HENRY G. BOHN, YORK STREET, COVENT GARDEN.

1848.

## P R E F A C E.

---

In ushering the following pages into the world little seems necessary in the way of exordium.—It may be remarked, however, that works professedly of a similar description have appeared before ; but none within the period of the last twenty-seven years ; since which, the improvements in almost every thing which relates to the subjects contained in the following pages have been so numerous and important, that the Chase, and its collateral appendages, may be said to have assumed a very different character. What indeed may have been called “*Sportsmen’s Dictionaries*” were publications evidently huddled together by persons whose knowledge of Field Sports was confined to *hearsay*, or what they had gleaned from spurious works which have at different times made their appearance : in consequence, these “*Sportsmen’s Dictionaries*” not only abounded in errors, but were so grossly absurd, for the most part, that, so far from imparting amusing and interesting instruction, they excited the contempt and derision of the genuine enlightened Sportsman. Under these circumstances, therefore, the want of a Work like the present appeared evident ; and if it cannot lay claim to unqualified originality, it certainly possesses the advantage of having been put together by a long-experienced and a practical Sportsman—one who has pursued the Chase in all its ramifications from almost childhood to what may be called the afternoon of life :—he has studied the Chase not only as a Sportsman, but as a philosopher and a physiologist ; and in the following pages has endeavoured, in a genuine, character-

istic manner, to present all that can be interesting or useful to the professed Sportsman, and to those who are attached to, or occasionally pursue, the healthful, the invigorating, the highly-fascinating and delightful amusements enumerated in the title page.

At the same time, the author and compiler very frankly acknowledges, that he has freely availed himself of whatever has hitherto appeared in print upon subjects connected with the present publication : this, however, was not a task of very great or extensive labour ; since, comparatively speaking, little has been written upon subjects evidently interesting to the human feelings above all others. The reason is obvious : Sportsmen capable of expressing their opinions upon paper are almost uniformly placed in situations and circumstances where literary exertion is not necessary as a means of existence ; and, being occupied with the fascinating pleasures of the Chase, feel no desire to give their opinions to the world thro' the medium of the press. In consequence, works of this nature have been for the most part, put together by men, who, whatever might be their attainments in other respects, possessed no practical knowledge of Field Sports. These observations are not intended to apply to Veterinary Subjects, upon which many publications have appeared, several of them evidently the productions of acute and enlightened minds ; tho' the "art of healing," as far as relates to horses, must still be considered in its infancy.

Finally, the following pages are intended to form, not merely a book of general reference, a kind of copious index ; but a compendious, interesting, and complete Library of every thing essentially connected with the Sports of the Field.

# THE SPORTSMAN'S ENCYCLOPEDIA.

## A

AARON, bay, was bred by Lord Chedworth, in 1747; he was got by Whitenose, out of Diana, by Whitefoot. In 1751, Aaron won the £50 purse, for four-years-old, at Burford, beating Fearnought, by Second, and nine others. Aaron's running, in 1752, proved unfortunate: in the spring he was beat by Lord Eglintowne's Lightfoot, at Newmarket; at Epsom, in May, he ran second to Lord Onslow's Victorious; in August, at Burford, he was again obliged to yield to Lord Onslow's Victorious. He afterwards became the property of Mr. Rogers; and in May, 1753, he was beat in a give and take plate, at Epsom, by Capt. Vernon's Driver, Aaron, however, winning the first heat. In June, he carried off the Ladies' Plate, at Guildford, beating Lord Onslow's Why-Not; in August, he won a £50 plate, at Hounslow; in September, he beat the Duke of Hamilton's Figure, give and take, at Winchester.

*Town Plate of £50, at Epsom, on May 25th, 1754.*

Mr. Rogers's bay horse, Aaron,  
weight, 8st. 6lb. 2oz. . . . . 1 0 1

Mr. Lamago's chesnut horse, Little Driver, by Beaver's Driver, out of Childers' Mare, weight, 9st. 11lb. 12oz. . . . . 2 0 2

The second heat was run so near, that the judge could not determine which had won it, and the third heat he gave to Aaron. This, however, was not fully determined till September following, at which time a paragraph appeared in the London Evening Post, including the affidavit of the judge in this affair.

Isaac Tarratt, of Epsom, in the county of Surrey, linen-draper, maketh oath, and

## A

sayeth, that, in the month of May last past, he, this deponent, was requested to observe and give his judgment respecting a certain horse-race, run on Epsom Downs, in the said month of May, between a horse, the property of Mr. Aaron Lamago, known by the name of Little Driver, and another horse, the property of Mr. Benjamin Rogers, known by the name of Aaron. And this deponent sayeth, that, according to his, this deponent's strict observance and belief, Mr. Rogers's said horse, Aaron, clearly won the third heat, against Mr. Lamago's said horse, Little Driver. And this deponent further maketh oath, and sayeth, that he had no bets depending, was nowise interested in, nor could he receive any benefit or advantage whatsoever from, the decision or event of the said horse-race, [one way or the other.]

“ISAAC TARRATT.”

“Sworn at Epsom, in Surrey, the 6th of September, 1754, before me,

EDWARD NORTHEY.”

“I do hereby declare my full consent to the above determination. September 14th, 1754.

AARON LAMEGO.”

In August he beat Lord March's Danby Cade, £50 give and take, at Romford; in September, he was beat by Little Driver, at Maidenhead, £50 give and take. In the first heat, near the ending post, both horses fell, and threw their riders, occasioned by the crowd breaking in upon them. September 26th, at Chipping Norton, Oxon, he won £50 give and take, beating Lord Ferrars's Mark Antony and another. In May, 1755, this famous little horse won another give and take, at Epsom, beating Lord Eglintowne's Lightfoot and another. On August 5th, he fell lame

in running at Reading; on the 19th, we find him at Oxford, where he was beat by Lord Onslow's grey horse, Martin. This excellent horse, which has never been surpassed in lastingness and determined perseverance, was under fourteen hands in height.

**ABACK.** This word is variously applied in the sports of the field, but pronounced *Back*.—*Hark Back!* is a term used to recal those hounds which have over-run the scent; and, indeed, various occurrences may happen in the field to induce the application of this word: in a run with a fox, for instance, which the writer once saw, after running for some time, a fresh fox broke away from some bramble bushes, which the hounds were passing at the time, and while they were viewing the original chase; several of the tail hounds, however, divided, and attempted to run the fresh fox: *Tallyho Back!* was used to call them off, and induce them to rejoin the pack: hence, the application of the term may be easily understood. In giving the expression, perhaps, were the strict rules of punctuation attended to, another mark of exclamation should be used, thus—*Tallyho! Back!* but as the term or phrase is generally spoken or hallooed without any distinctive pause between the words, so one of the marks of exclamation has been omitted, in order to make it appear better in the eye of the sportsman, though not in the estimation of the inveterate cynic or the carping critic. Similar instances may occur in the course of the work, which, we trust, after this short explanation, will be perfectly understood.

The word *Back* is also applied to pointers:—when one dog has made a point, the others, the moment they perceive it, should immediately stop; and this is termed *backing*; or the dogs, in this case, are said to *back*.

**AB-AMBOBUS.** Of those invaluable sources whence Eclipse and Highflyer deduce their origin, (neither of which horses were ever beat) it is, that this horse boasts his pedigree. He was bred by Mr. O'Kelly, in 1782; got by Eclipse, out of Harmony, by Herod; grandam, Rutilia, (sister to the dam of Highflyer) by Blank; great-grandam by Regulus; great-great-grandam by Soreheels; great-great-great-grandam by Makeless, out of Kit D'Arcy's royal Mare. Abambobus was own brother to Scots; he was himself a good runner, and, though early lamed, in the name of Chanter, beat several of the best horses of his day:—Alexander, Balloon, Spartacus, Le Picq, Gran-

tham, &c. &c. He was fifteen hands three inches high, remarkably full of bone, in colour bay, and the first produce of his dam.

**ABATURES.** Foiling the sprigs or grass which are thrown down by the stag or deer in passing.

**ABBA THULLE**, bay, bred by Mr. Dodsworth, in 1786, got by Young Marske, dam by Chatsworth, grandam by Engineer, Wilson's Arabian, Hutton's Spot, Mogul, Crab, Bay Bolton, Curwen Barb, Spot, White legged Lowther Barb, Vintner Mare. In 1789, Abba Thulle won £50 at Durham; 1790, twice £50 at Hexham, twice £50 at Lancaster, and the gold cup at Doncaster; 1791, £50 at Preston, Lancaster, Morpeth, Dumfries, Perth, 140 guineas at Nantwich, the gold cup at Richmond, and the King's plate at Carlisle; 1792, £50 at at Preston, and Doncaster, and 80 guineas at Nantwich; 1793, the gold cup at Richmond, and 210 guineas at Nantwich. Abba Thulle now became a covering stallion; he was sire of Milbanktonia, Airy, &c. He was sold to Russia.

**ABBATIS.** A sort of steward of the stables, or hostler; called also an Avenor. An obsolete term.

**ABDOMEN.** The cavity in animals containing the intestines or bowels, liver, stomach, kidneys, &c. commonly called the belly. It is divided from the thorax or chest, by the membrane called the diaphragm, skirt, or midriff.

**ABORTION.** Miscarriage, or slipping the foal. Mares that are overworked when far gone with foal, are liable to this accident; it may also be brought on by any thing which causes the mare to strain and struggle much, or from being struck or kicked on the belly. The best way to prevent abortion is, not to allow the mare to work during the latter months of gestation.

**ABSCESS.** A collection of matter generally arising from a bruise or other injury.

**ABSORBENTS.** Chalk, prepared oyster-shells, bole, and many other substances that readily take up or absorb fluids, are thus called:—preparations of this kind are sometimes given to the horse, with the intention of correcting any hurtful matter that may be supposed to exist in the stomach. They are, however, seldom productive of any good; and in the cases where they were formerly given, mild purgatives are now found to answer much better.

**ABSORBENT VESSELS.** These are

small transparent canals, which are supposed to exist in every part of the body of an animal; their office is to absorb any useless fluid, or other matter, that may be in the cavities or other parts of the body. They are divided into lacteals and lymphatics.

ACACIA, chesnut, bred by Mr. Pantton, 1787, got by Turf, out of Madonna, by Herod; grandam by Snip, Bay Bolton, Darley's Arabian, Byerly Turk, Place's White Turk, natural Barb mare. Of Aca-cia's exploits we have but little to record; in 1791 he won £50 at Lewes, beating Bustler, Gunpowder, and Æolus. He was sire of Lismahago, Paulina, &c.

ACCLOYED. An obsolete term in farriery; it has been used to signify an injury sustained in the foot by shoeing; as when a nail had swerved from its proper direction, and punctured, or pressed too close upon, the membranous mass, so as to occasion lameness; the horse was then said to be *Accloyed*.

ACIDS. Medicines that have a sour taste. Acids are divided into three classes; the mineral, vegetable, and animal acids. The mineral acids used in veterinary practice are the sulphuric, the nitric, and the muriatic. The vegetable acids, the acetic, or acetuous acid, commonly known by the name of vinegar; and the tartaric acid, or rather its combination

with a small proportion of potash, which is named cream of tartar.

ACOPUM. We sometimes meet with this word in old veterinary authors; it signifies a composition used by the antients, as a cordial or stimulant. It consisted of about thirty ingredients; some of which were powerful stimulants. They used it both internally and externally.

ACRIMONY is a state of the blood disposing it to certain diseases, by the quantity of the serum in the blood becoming too great for the proportion of crassamentum with which, in its state of active fluidity, it is combined, for the purpose of regular circulation, so necessary to the health of the animal. Blood, thus deprived of its properties, soon displays, in horses, a tendency to those diseases which are termed *acrimonious*.

ACTION is a word much used by the sporting world, to signify the peculiar property of a horse by his *good* or *bad* action.

ACTUAL CAUTERY. The application of red-hot iron, as in firing, docking, &c.

ADAMANT, bay, bred by Lord Grosvenor, 1755; was got by Herod, out of Seraphina, by Blank; grandam by Blaze; great-grandam by Greyhound; great-great-grandam by the Curwen Bay Barb. Adamant covered in Leicestershire at five guineas.

ADDER.—The term *Adder-stung* is indiscriminately applied, in some parts of the country to the bites and stings of venomous animals and insects without distinction. The adder or viper seldom exceeds two feet in length, though they are sometimes found more than three. The ground colour of their bodies is a dirty yellow, deeper in the female than in the male. The back is marked throughout with a series of rhomboidal black spots, joining each other at the points; and the sides have triangular ones. The belly is nearly black. They are chiefly distinguished from the common snake by their darker belly; their head much thicker than the body, and in particular by the tail; which, though it ends in a point, does not run tapering to so great a length as in the snake. When, therefore, other distinctions fail, the difference of the tail may be distinguished at a single glance. Vipers are common enough in morasses and fenny places, as well as in dry and sandy banks; in all probability, they frequent the former in summer and the latter in winter. The adder, like the rattlesnake, and all other venomous serpents, has two large teeth or fangs that issue from the upper jaw, and that hang out beyond the lower: these are only to be found in those serpents which are venomous, the common snake being destitute of them. The wounds which these fangs inflict produce the most dangerous symptoms; while the wounds

## A D D E R

inflicted by the teeth only, are attended with nothing more than the ordinary consequences of the bite of any other animal. The adder is furnished with an elaboratory where the poison is formed, a canal by which it is conducted to the jaw, a bag under the tooth for keeping it ready for every occasion, and also an aperture in the tooth itself for injecting it into the wound. To be more particular, the glands that serve to fabricate this venomous fluid, are situated on each side of the head behind the eyes, and have their canals leading from thence to the bottom of the fangs in the upper jaw, where they empty into a kind of bladder, whence the fangs on each side are seen to grow. The venom contained in this bladder is a yellowish, thick, tasteless liquor, which, injected into the blood, produces the most alarming consequences, or perhaps death. This poison, according to Dr. Mead, when diluted with a little warm water, and applied to the tip of the tongue, is very sharp and fiery, a sensation taking place as if the tongue had been struck through with something scalding or burning. This, he says, goes off in two or three hours. One person mentioned by Dr. Mead, tried a large drop of it undiluted; in consequence of which, his tongue swelled, with a little inflammation; and the soreness lasted two days. Other persons, on the contrary, assert that it has no particular acrimony of taste; but that, in this respect it rather resembles oil or gum. Contradictions somewhat similar have taken place relative to the effect of viperine poison taken into the stomach. Boerhaave asserts that it produces no ill effect whatever; while the Abbé Fontana maintains a contrary opinion, although he admits that it possesses no unpleasant taste. We are told, however, that, in the presence of the Grand Duke of Tuscany, while the philosophers were making elaborate dissertations on the danger of the poison taken inwardly, a viper catcher, who happened to be present, requested that a quantity of it might be put into a vessel, and then, with the utmost confidence, and to the astonishment of the whole company, he drank it off in their presence. Every one expected the man instantly to drop down dead; but they soon perceived their mistake, says the relater of the story, and found, that, taken inwardly, the poison was as harmless as water.

The fangs that give the wound are large in proportion to the size of the animal that bears them; crooked, yet sharp enough to inflict a ready wound. They grow, one on each side, and sometimes two, from two moveable bones in the upper jaw, which, by sliding backward or forward, have a power of erecting or depressing the teeth at pleasure. In these bones are also fixed many teeth, but no way venomous, and only serving to take and hold the animal's prey. Besides this apt disposition of the fangs, they are hollow within, and have an opening towards the point, like the slit of a pen, through which, when a fang is pressed down upon the bladder where it grows, there is seen to issue a part of the venom that lay below. To describe this operation at once:—when the adder is irritated to give a wound, it opens its jaws to the widest extent; the moveable bones of the upper jaw slide forward; the fangs that lay before inclining, are thus erected; they

## A D D E R

are struck with force into the flesh of the obnoxious object ; by meeting resistance at the points, they press upon the bladders of venom from whence they grow ; the venom issues up through the hollow of the tooth, and is pressed out through its slit into the wound, which, by this time, the tooth has made in the skin. Thus, from a slight puncture, and the infusion of a drop of venom scarcely larger than the head of a pin, the part is quickly inflamed, and without a proper antidote, the whole part completely contaminated. Hence, it would appear that the venom of the viper is perfectly innoxious when taken internally ; as little doubt can be entertained that the adder, in seizing its prey, injects a portion of the noxious fluid into the animal, which it immediately swallows. It is, then, the infusion of the liquid into the blood, that causes these alarming consequences which have repeatedly been witnessed : nor, indeed, is it to be wondered at, when we consider that even milk, and also atmospheric air, when injected into the blood, produce death.

The appearances which the bite of the adder produces will be found to vary according to the strength of the reptile which strikes the blow ; or the season may also perhaps have some influence in the same way. If an adder bites a human being, and the wound be neglected, it first causes an acute pain in the affected part, followed by a swelling, first red and afterwards livid. This by degrees spreads to the neighbouring parts ; great faintness, and a quick, though low and interrupted, pulse ensues ; to this succeed great weakness at the stomach, bilious and convulsive vomitings, cold sweats, pains about the navel, and death itself. Nothing can more justly excite one's wonder than that so small a portion of venom should produce such powerful and deadly effects.

The most esteemed and best remedy for the bite of the viper or adder, is olive oil ; salad oil, or common sweet oil, will answer the same purpose ; and perhaps other vegetable oils would effect a cure ; but animal oil in all probability would have no such effect. Of the efficacy of common sweet oil, the writer was an eye witness. Some years ago, in the month of August, he went, accompanied by a setter dog (which would take the water) to a marshy, fenny spot, for the purpose of shooting young wild ducks ; when, after about a quarter of an hour, the dog was bitten by an adder in the nose, which swelled to a prodigious size immediately. Aware of the remedy, the writer hastened to the nearest house, distant nearly two miles ; and by the time he reached it, the dog's nose appeared frightful. Fortunately there happened to be some sweet oil in the house, which was immediately rubbed on the wound, and the swelling around it : the part affected was rubbed for a considerable time at intervals, though the surprising effect of the oil was very soon remarkably conspicuous. In the course of an hour, the dog appeared perfectly recovered, and the next morning not the slightest swelling or affection was perceptible. In case a human being is bitten by an adder, sweet oil will be found equally efficacious. An adder, having once bitten, exhausts for that time the greatest part of its poison ; and though the wound caused by its biting a second time, will be attended with some malignant symptoms,

yet they will be much milder than before. It has been proved by experiment, that a serpent biting upon a sponge, or piece of soft bread, and then biting a dog immediately after, did not inflict a wound more dangerous than the prick of a needle.

The progressive motion of the adder is slower than that of the snake; from which it also differs in the manner of bringing forth its young, which are excluded completely formed and alive; while the snake deposits eggs, which are hatched afterwards by atmospheric heat. Adders are supposed to copulate in May, and to bring forth three months afterwards; they have seldom more than eleven eggs at a time, and these are of the size of a blackbird's, chained together in the womb like a string of beads. Each egg contains from one to four young ones, so that the whole of a brood may amount to twenty or thirty. They continue in the womb till they come to such perfection as to be able to burst from the shell, and, it is said, that they creep from their confinement by their own efforts into the open air, where they continue for several days without taking any food whatsoever.

**ADDER-STUNG.** Horses are often stung by wasps, hornets, and a large fly, called, from its stinging the horse so frequently, "the horse-fly:"—these are generally all called by the above term, by those who do not take the trouble to think that these insects are much more common in our pastures than the viper or adder.

**ADMIRAL**, bay, bred by R. Vernon, Esq., 1779, got by Florizel, dam (sister to Juno) by Spectator; grandam (sister to Horatius) by Blank, Childers, Miss Belvoir. Admiral won races of 1500 guineas, 300 guineas, 50 guineas, 100 guineas. He beat Sweet William, a match, 500 guineas; a plate, three miles, beating Regent and five others; a match, the Duke of Bolton's Achilles, by Eclipse. He was about fifteen hands and a half high, full of bone, and covered at Buntingford at two guineas.

**ADOLPHUS**, roan, bred by Mr. Martindale, 1750; got by Regulus, out of Miss Layton, (Lodge's roan mare) by Partner; grandam by a horse bred by Lord Cardigan, got by the Duke of Richmond's Turk, out of a full sister to Leedes; great-grandam by Why-Not; great-great-grandam by Wilkinson's bay Arabian, out of a natural Barb

mare, bought by Mr. Wilkinson of Lord Arlington, secretary of state to King Charles II. to whom she was a present from the emperor of Morocco.

**ÆGYPTIACUM.** The mil ægyptiacum, so much used by some farriers as a detergent dressing, in foul and indolent ulcers, is made in the following manner:—take one pound of honey, five ounces of powdered verdigris, and seven ounces of vinegar; boil these all together, until the mixture is of a deep red colour, and as thick as the honey was before mixing it with the vinegar.

**A. F.**, in the language of the turf, is an abbreviation of "across the flat," a course for two-year-olds, of one mile and a quarter, at Newmarket.

**AFFOREST.** To afforest is to turn land into forest; and, on the contrary, to disafforest is to convert a forest into cultivated ground.

**AGARIC.** A fungous substance, growing on the oak and other trees. Agaric has been used as a styptic; but at present is seldom, if ever, employed in modern veterinary practice, as more effectual means may, on all occasions, be found.

**AGE.**—The following rules for determining the age of different animals, as well as of the horse, will be found extremely serviceable to sportsmen;—we shall begin with the rules for knowing the

**AGE OF THE DOG.**—The age of a dog may be ascertained, in a very great degree, by the appearance of his teeth. When a dog is twelvemonths old, his teeth will present a very white, clean appearance; and the front teeth will be completely serrated: as the animal advances

in life, this saw-like appearance will gradually wear away; at two years old, it will be very perceptible; at three, it may still be discerned, but at four, nothing of it is to be seen: if the dog be chiefly fed on bones, the serrated appearance of the front teeth will much sooner disappear than when he is principally fed upon soft provisions. The front teeth are the first to wear away and fall out; though, as the animal advances in age, the fangs or canine teeth become obtuse and discoloured towards the bottom; and indeed the mouth altogether assumes an appearance sufficiently indicative of the subject in question, and which can never be mistaken by those who have paid the slightest attention to it. But there are other appearances expressive of advanced age, which are obvious to the most superficial observer, namely, the dimness of the eyes, and a grayness about the nose and head; and these will be perceptible (early or late) according to the constitution of the animal, or according to the labour or fatigue he has undergone. A pointer which is worked very hard will often manifest symptoms of old age by the time he has reached his seventh or eighth year; while one that has only moderate exercise will not exhibit such appearances till ten or twelve; the same observations will apply to the greyhound; but, of all the dog tribe, none shews age at so early a period as the foxhound; this arises from the nature of his occupation; and thus, as he frequently undergoes the most violent exertion, and the most excessive fatigue, so he becomes old at an early period (if the expression may be allowed); and may be said to be worn out precisely in proportion to his labour. The age of a fox may, no doubt, be ascertained in the same way.

**THE AGE OF A HART OR STAG** may be tolerably well known by the furniture of his head. At a year old, there is nothing to be seen but a horny excrescence which is short, rough, and covered with a thin, hairy skin. The next year the horns are single and straight: the third year they have two antlers; three the fourth; four the fifth; and five the sixth: this number is not always certain, for sometimes there are more and often less. When the hart is arrived at the sixth year, the antlers do not always increase; and, although the number may amount to six or seven on each side, yet the animal's age is then estimated, rather from the size of the antlers and the thickness of the branch which sustains them, than from their variety.

**THE AGE OF THE HARE.**—A young hare, that has attained its full growth, may be known from an old one by feeling the knee joints of the fore legs with the finger and thumb nail. When the heads of the two bones, which form the joints, are so close that little or no space is to be perceived between them, the hare is old. If, on the contrary, there is a perceptible separation, the hare is young; and is more or less so in proportion to the separation of the bones. It may also be known, whether a hare is old or young, but without pretending to ascertain the precise age, by compressing the under jaw bones; if they break at the point immediately under the fore teeth, upon a slight degree of pressure, the hare is certainly a young one; but if considerable force is required, the contrary may be inferred. The same remarks will apply to the rabbit.

**THE AGE OF FEATHERED GAME.**—Young grouse are sufficiently distinguished by their smaller size the greater part of the shooting season to need any further distinction; and after the first year, there is no criterion by which to judge of the precise age of this bird. While partridges are young and their plumage is not complete, they may be distinguished from the old ones by the first feather of the wing, which terminates in a point like a lancet; whereas, in those which are not of the last brood, this feather is round at the extremity; but this distinction ceases after the first moulting:—also, the bill of the young bird is brown, while that of the old one is a bluish white; the legs of the old ones a sort of bluish or slate-coloured gray; those of the young are yellow. Young pheasants are much smaller than the old birds; and till the moulting season, their plumage is similar to that of the hen. After moulting, the young male birds assume the elegant plumage of the cock, but yet are sufficiently distinguishable from the old male bird by their size, as well as from the spurs on the leg, which, in the young male bird, appear like blunt protuberances; indeed, a tolerable idea of the age of the cock pheasant may be formed from the spurs, which evidently increase in length for some years. Generally speaking, the age of the pheasant may be ascertained much in the same manner as that of the partridge.

**AGE OF THE HORSE.**—There are no certain marks by which we can judge truly of the age of a horse but his teeth; and these only for a certain time: after that time, there is no method to be depended upon, but we may form a good guess by the front teeth of his upper jaw, until he is about twelve or thirteen; especially if we take into consideration the countenance of the horse, with some other marks which we shall point out.—A horse has forty teeth, twenty-four called *grinders*, from which we learn nothing of his age; then six above and as many below, in the fore part of his mouth, called *gatherers*, or *cutting* teeth, and it is from these we know his age; then four tusks, two above and two below, sometimes named *bit teeth*, making in all forty. Mares generally have no tusks, their teeth are therefore only thirty-six. When a colt is foaled, he has no teeth in the front of his mouth; in a few days, two above and two below make their appearance; soon after these, four others appear; after these, it is usually three or four months before the corner teeth make their appearance. These twelve colt's teeth in the front of the mouth, continue without alteration, till the colt is two years or two years and a half old; he then begins to lose his colt's teeth for permanent ones, sooner or later, according to the manner in which he has been fed.

As it is from the front teeth of the *lower* jaw a horse's age is known, until he is in his eighth year, it is to these only we shall confine our attention. At about two years and a half old, he sheds the two middle teeth of the six; (as these first appear in the colt's mouth, so are they the first to disappear); these are succeeded by two permanent or horse teeth, stronger, of a deeper colour, and grooved or fluted from top to bottom, with a black cavity in the centre; he is now rising three.

His mouth continues thus till some time in the latter part of the fourth year, when the same process takes place with the teeth on each side of the two in the centre; so that at four years old, he becomes possessed of four horse teeth in the middle, with their natural black marks in the centre; and one colt's tooth only on each side.

The next he sheds are the two remaining, or corner teeth; when he has got the successors to these, his mouth is full; he is then called a horse, five years old: he has the black mark now in all the six front teeth.

During the course of this year, the *tusks*, situated beyond the corner teeth, upon the bars, appear: he is now five years old, off; and through the whole of the year is "rising six:"—we say, "he will be six years old next grass." Sometime in the last six months of the sixth year, the black cavities of the two middle teeth are gradually filled up; and when he is *turned* six years old, they are nearly, or quite smooth upon the surface. In the latter part of the seventh year, when the horse is termed "six off," six past, or rising seven; the teeth on each side of the two centre ones, become gradually possessed of the same appearance; and when he is seven years old, the two outside or corner teeth only, are marked with the black cavity.

TWO YEARS AND A HALF.

RISING THREE YEARS.

FOUR YEARS.

FIVE YEARS.

SEVEN YEARS.

After this period, the horse is said to be aged ; and from this time to the completion of his eighth year, the mark in the corner teeth continues gradually to disappear, till it is quite gone, when the age by the teeth is no longer known. He is now “past the mark of the mouth.”

After this period, you may judge of the age by the marks or cavities in the *upper* teeth. At about ten, the two front teeth have lost their marks ; the two next them have but little left, but in the corner teeth these marks may be readily seen ; these gradually wear out, and during the twelfth year are quite erased. The tushes, like the teeth, are gradually changing their appearance ; they are small, sharp, and shell-like at first, and are grooved on their inner surface ; they gradually become larger and longer ; the concavities or grooves on their insides also lessen ; and at about eight, they are nearly lost. At about eleven and a half, or twelve, the inside of the tush begins to approach towards a round form, and after becomes quite round ; they are then blunt at the top and of a yellowish brown colour. The teeth of horses as they advance in years, appear longer, from the gums shrinking from them, they get more oblique in their position ; they also acquire a much darker colour. Horse dealers are said to practice numerous artifices in order to deceive their customers, with respect to their horses' ages : one of these is termed *bishopping* ; that is, making artificial marks in the teeth, when the natural ones are worn out ; but there is always a want of resemblance between the natural and artificial mark, you may likewise compare them with the state of the tushes. They also knock out the corner teeth of four year olds, to make them appear five ; for when these are removed before their time, they are soon succeeded by horses' teeth : this may be detected by the want of tushes. In racing, all horses take their ages from May-day.

**AIR-GUN.** This is an instrument neither so well known, so common, nor so generally applicable to the purposes of the sportsman, as the fowling-piece. This treacherous engine has been long known, but at what period it was first introduced cannot be ascertained with precision. In England the use of the air-gun is better understood than in any other part of the world, where it is manufactured in various forms, and altogether in a very superior manner. As the projectile force, or power of impulsion, arises, in the fowling-piece, from compressed air, so, in the instrument under consideration, the power is produced by compressed air also, but of a different quality ; it is consequently procured in a different manner, and the discharge of it is far less effective. It is the usual calculation, that gunpowder contains a thousand times its own bulk of fixed air ; or, in other words, that a grain or a charge of gunpowder, on its ignition, generates an air or fluid, which expands one thousand times larger than the original bulk

from which it was produced ; consequently, gunpowder will be strong in proportion to its expansive power on ignition : this gaseous fluid, for the sake of distinction, we will call inflammable air (as it is not our object to enter into a chymical analysis or disquisition.) Thus, while the fowling-piece derives its force in the manner just described, the engine which forms the subject of the present article, is discharged by the compression of atmospheric air, and the force of the discharge will, of course, always be found in proportion to its power of compression.

Air-guns are made in the form of the fowling-piece or musket, with the addition of one or more spheroidical balls, into which the air is forced, by means of an instrument or pump made for the purpose. One of these balls, when filled, is attached to the gun by means of a screw immediately under the breech, and, by pulling the trigger, the valve is momentarily forced open, a portion of air escapes into the gun-barrel, and thus the ball is discharged.

Hence it results, that the first discharge will be the most powerful or strongest, and that every successive discharge will become weaker and weaker, till it is absolutely ineffectual. The number of effective discharges will of course be in proportion to the size of the ball, and of the strength which is applied to the forcing-pump. For rook-shooting the air-gun is preferred by some to the cross-bow, particularly since it has been manufactured in such a form as to offer no very indifferent resemblance to a stout walking-stick. An air-gun thus becomes very portable, as the pump which is applied to these walking-stick air-guns may be easily put into a common-sized coat-pocket without inconvenience. Instead of spheroidal balls, as in the former case, for containing the compressed air, the walking-stick air-gun is so contrived, that the breech of the barrel answers the same purpose. They are more powerful engines than the cross-bow, while the discharge of them is attended with very little noise, and no re-percussion whatever. In the fowling-piece, it was formerly considered, that the force of the discharge would be in proportion to the length of the barrel, (see the article FOWLING-PIECE;) and this erroneous notion was equally applied to the air-gun; and, in consequence, air-guns were formerly made of a much greater length than necessary, and the force of the discharge decreased accordingly.

For buck or deer-shooting, the best air-gun is not sufficiently powerful; for rook-shooting it is very well calculated; and could we stop here, it would be all very well; but this mischievous instrument has sometimes been applied to the most diabolical purposes; and has at length found its way into the hands of the poacher, who very willingly uses it for nocturnal depredation.

Air-guns are principally made in Birmingham; and those which are used by the poachers, are manufactured so as to represent those stout walking-sticks which are formed rough, in imitation of the bark of trees. This disguises the instrument so completely, that a close inspection only will enable a person to discover the deception. Air-guns are used with the most destructive effect amongst pheasants, as these birds roost on trees during the winter, and are easily brought down by them, and that, too, without the noise and alarm which cannot fail to result from the discharge of the fowling-piece.

**AIRING OF HORSES.** When a horse is not in work, and stands all day shut up in the stable, it is quite impossible for him

to enjoy health, without regular airings. if kept in the stable without exercise, his strength fails, he loses his appetite, and his breathing becomes thick. The best time for airing horses is early in the morning, and he should be kept out two hours or more. These airings will keep him in health, and make him capable of ordinary exertion, or moderate work.

**ALANDES.** An obsolete term for wolf-dogs.

**ALANERARIUS.** An obsolete name for the keeper or manager of spaniels or setting-dogs, used in hawking; also a falconer.

**ALCOHOL.** Rectified spirit of wine.

**ALIMENT** is that which affords nourishment to the animal. The best food or aliment for horses that work in a moderate way, is good hay and oats; beans are certainly of great use for those which are harder worked; sweet clover hay, cut short, is a useful addition to these. Some horses thrive, and look sleek, and in condition, with a much less quantity of food than is required to produce any thing like the same appearance in another; and such horses should be fed accordingly, though they should be allowed no more than is really necessary. The best plan is to give them a little at a time, and often; they will thus make less waste, and enjoy it much more. It is one of the worst things for the horse, to let him stand long without something before him to eat; it is productive of many diseases. The horses used in the mines of Wales suffered much, and many were lost, by the disease called the sleepy staggers, which has its seat in the stomach, and may be said generally to arise from over-distension, produced by previous debility from long fasting. These horses now always wear nose-bags when at work; and the disease has left the mines. Horses that are used merely for short rides, and taken out only occasionally, should have bran mashes now and then, or they may be fed constantly with a mixture of bran and oats; this is of great use when the horse is inclined to costiveness, and in such cases green meat will be of service.

**ALL-AGE** stakes or plates, are those for which start any horse, mare, or gelding, including three-year-olds, carrying weight according to their age, with allowances, and sometimes extras, according to circumstances.

**ALLAY.** To allay a pheasant, is to cut or carve it at table:—we need not tell our readers that it is perfectly obsolete.

**ALLOW, or ALLOWANCE.** An archer

is said to allow, or make allowance for the wind, when he shoots somewhat wide of the mark, and on that side nearest the wind, in order that the wind may bring his arrow into the line of the mark.

**ALLOWANCE**, in the language of the turf, signifies a certain weight (usually three pounds each) which mares and geldings are allowed to carry less than such horses as they may be running against; also, if coming of untried parents, three pounds is allowed for horses, mares, and geldings, against those who come of tried parents. Fillies always carry less than colts, by two, three, four, and sometimes even five pounds; this, however, is not called by any name.

**ALLURE**. To allure is to draw to the line or bait.

**ALODARICS**. Lords of free manors—lords paramount.—*Obsolete*.

**ALODIUM**. A free manor.—*Obsolete*.

**ALOES** are distinguished by the name of the place from whence they are brought. The Socotrine aloes are brought from the island of Socotra, and are supposed to be more safe in their operation than the other kinds. This aloe is of a dark brown colour, opaque, and has a less disagreeable smell than the others. The Barbadoes aloe is brought from Barbadoes, and has been generally considered apt to produce griping, and other unpleasant effects; it is of a darker colour than the former kind, less brittle, and of a stronger and more disagreeable smell. It is more active than the Socotrine, and for that reason is more used in veterinary practice than it, though this kind of aloes has its advocates. The Cape aloe is rather transparent, very brittle, easily powdered, and is of a bright yellow colour; its smell is not so strong as the Barbadoes, but stronger and less agreeable than the Socotrine. It is much lower in price than either of the others, but is so uncertain in its effects, that it is hardly ever employed in medicine. The aloe is the most effectual purgative for horses with which we are acquainted; it is generally made into balls with the addition of soap, which makes them operate more speedily. The dose of Socotrine aloes is about six drachms; Barbadoes, from four to six drachms; and of the Cape aloes, from six to seven drachms; but the dose depends upon the form of the horse, and not his size, as might be supposed.—*See Purging*.

**ALTERATIVES** are medicines which act very gradually on the system, and without any very sensible increase or di-

minution of the natural evacuations. Those most commonly used in veterinary practice, are antimony, sulphur, nitre, resin, Æthiop's mineral, &c. Alteratives require to be continued for a long time; and the cases in which they are most commonly employed, are diseases of the skin. They act by producing an increased discharge from the bowels, the kidneys, or the skin. One of the best alteratives in many cases, is a run at grass, for a month or two; and when this can be given, it will often do away with the necessity for medicines. When this cannot be done, feeding in the stable, on vetches, lucerne, &c., will be found a good substitute.

**ALTISIDORA**. This celebrated mare, the winner of the Doncaster St. Leger, 1813, was bred by R. Watt, Esq. Altisidora, chesnut, was got by Dick Andrews, out of Mandane, sister to Enchanter, by Pot-8-os; grandam Young Camilla, sister to Colibri, by Woodpecker; great-grandam Camilla, by Trentham; great-great-grandam Coquette, by the Compton Barb, out of a sister to Regulus, by the Godolphin Arabian.

**Performances**.—1812, April 8th, 60 guineas at Malton; May 27, 180 guineas at York. 1813, May 25, 80 guineas at York; September 27, the great St. Leger, Doncaster; September 30, a sweepstakes of 320 guineas at Doncaster. 1814, August 22, a match, beating Cameleopard, 500 guineas, at York; a sweepstakes, 250 guineas, beating Catto Llangold and Georgiana; September 29, walked over for the club stakes at Doncaster. 1815, August 23, one of the great subscriptions at York; September 25, the Fitzwilliam stakes at Doncaster; September 28, a sweepstakes of 75 guineas at Doncaster; October 11, the King's plate at Richmond.

**Produce**.—1817, chesnut colt Cæsar, by Cerberus. 1818, chesnut colt Cataline, by Cerberus. 1819, chesnut filly by Rubens. 1820, bay colt Abron, by Whisker. 1821, chesnut filly by Blacklock. 1822, bay filly by Walton. 1823, chesnut filly by Catton. 1824, chesnut colt by Magistrate. Altisidora died January 23, 1825, at Bishop Burton, aged fifteen.

**ALUM**. A saline substance, possessing a considerable astringent power. It is often used, when burnt, combined with sulphate of copper, or red precipitate, to cleanse foul and indolent ulcers in horses. It is used internally, in doses from half an-ounce to an ounce or more.

**A. M.** Ancaster Mile at Newmarket; length, 1778 yards.

**AMAUROSIS.** A disease of the eye, attended with total blindness, without any altered appearance of the eye; it does not often occur in horses, and when it does is not easily distinguished, on account of the eye retaining its natural appearance. One plan for observing it is, by turning a horse loose into a place where want of sight will be discovered by his running against objects: but this can only be of use in discovering the disease, when he is blind of both eyes: a much better method is, to close the eyelids with your finger and thumb, and keeping the eye shut for a minute or two: on opening the eye, you will see the pupil, or black spot in the centre, grow larger, if he is not blind; but if it remains unaltered, of the same size, he has got amaurosis, which is a decay of the optic nerve, and is of course incurable.

**AMBER.** The essential oil of amber is the only preparation of this article which is used in veterinary practice; it is of a dark colour, and to most people its smell is very disagreeable. It was formerly much used as an ingredient in *strain oils*, combined with other oils, as turpentine. It has been given internally in spasmodic cases, in doses of from one drachm and a half to half-an-ounce; but for any purpose in which it was formerly used, we have now much more efficacious remedies.

**AMBLING.** A pace in a horse, almost peculiar to ponies and galloways; it is a very easy pace for the rider, but is now in very little use: formerly it was taught by forcing the animal to go with his legs tied; we now very wisely adhere to the natural paces of the horse, which are, the walk, trot, canter, and gallop.

**AMBROSIO**, bay, foaled in 1793, was got by Sir Peter Teazle, out of Tulip, by Damper, grandam by Eclipse; Rarity by Match'em, out of Snapdragon, by Snap; Regulus, Bartlett's Childers, Honeywood's Arabian, dam of the Two True Blues. In 1796, Ambrosio (the property of Mr. Lowther) won £50 and 150 guineas at York; after which, he was purchased by Mr. Cockson, and was a winner of 275 guineas at York, and the great St. Leger at Doncaster; 1797, the first class of the Oatland stakes, 100 guineas and 200 guineas at Newmarket; 1798, the third class of the Oatland stakes, 50 guineas, 200 guineas, the Jockey Club Plate, 25 guineas, 400 guineas, and 200 guineas, at Newmarket; 1799, £50 at Newmarket, £225 at York, and 200 guineas at Doncaster. Ambrosio covered at Barham Wood, near Edgeware, Herts, at ten gui-

neas; he was sire of Jewess, Black-and-all-Black, Frances, Rosario, Mousetrap, Brown Bess, Matilda, Huntingdon, Jack Spavins, &c.

**AMBURY.** A kind of wen, or spongy wart; they are generally found about the nose and sheath of horses. They are of various sizes, and are in appearance something like a large mulberry. When they are small at the part by which they grow from the body, tie a strong thread round them, and pull it a little tighter every day for about a week, when they will drop off. When the wart has fallen off, touch the part every morning with lunar caustic, for three days or more, which will destroy the roots, and prevent its returning. When they grow from the horse by a broad base, the best plan is to eat them off by means of some escharotic application, as the butter of antimony, powder of verdigris, &c.

**AMMONIA.** There are several useful preparations of this article kept by the veterinary surgeon. The carbonate of ammonia is a stimulant and cordial, and is given in doses from one to two drachms. The liquor or water of ammonia is used externally, as a useful stimulant for dispersing indolent lumps or tumours, formed into an embrocation, by mixing it with equal parts of sweet oil and oil of turpentine, to which camphor is added.

**AMMONIACUM.** Gum ammoniacum is an expectorant, and is given to the horse in doses of from two to three or four drachms. It is given in chronic cough, combined generally with the powder of squills; sometimes with camphor, opium, balsam of sulphur, or balsam of tolu. The horse should be bled, and take a purging-ball, previous to taking any of these expectorants, which will render them much more useful. It is only in chronic coughs, or those which have become habitual, that ammoniacum is useful. For those which are recent, and depending on inflammation, other means must be employed. (*See Cough*) There are two kinds of gum ammoniacum sold in the shops; the best is called drop ammoniacum, and is in small pieces or drops, of a whiter colour than the other sort, which is yellowish, and contains small pieces of wood, and other extraneous matter; when this is employed, these should be separated from the gum, by pounding it in a mortar, and sifting it.

**ANASARCA**, or external dropsy, is a collection of serous or watery fluid in the cellular membrane under the skin. It has often been called water-farcy by the farriers, with their usual inaccuracy. It some-

times affects only particular parts, as the lips, belly, or legs; at others it is diffused over the greatest part of the body. These swellings may be distinguished by their size, their coldness, and by their retaining the impression of the fingers for some time. It generally depends upon weakness; for horses which are poorly fed, as in low marshes, or on moors, are often affected with a kind of dropsical effusion, called by the country people moor-evil; and it is often attended with great danger.

ANCASTER DRIVER was bred by his Grace, 1727; Driver was got by Wynn's Arabian, out of the Lady mare, by Pert; grandam by St. Martin's. In May, 1732, he won the Wallasey stakes, in Cheshire, of 500 guineas; in October, the Wallasey stakes, at Newmarket. In 1733, the same stakes, of 600 guineas, at Newmarket, to which place they were removed, on the discontinuance of racing at Wallasey; he also beat Seymour's Archer, for the Ladies' plate, at Stamford; he likewise won the King's plate at Nottingham. The following summer closed his career as a racer,—he was let down in running at Northampton. Driver was sire of Frisky, Dizzy, and Mr. Villa Real's grey mare, Polly Bell, &c.

ANCHYLOSIS. Two or more bones becoming joined together, in consequence of injury, forming a stiff joint. Firing and blistering are the remedies usually employed; but they are almost always ineffectual. The writer of this article recollects a small horse, which for many years was used in the ring at Mr. Astley's amphitheatre; on dissecting him, several of the bones of the lones (lumbar vertibræ) were found united firmly together, in consequence of the injuries he had received from the continual vaulting and jumping on his back. This horse had several other peculiarities, all arising from the kind of work he had been employed in.

ANEURISM. A pulsating tumour communicating with an artery. This disease rarely occurs in horses.

ANGLE-BERRIES. Spongy excrescences, found on various parts of the bodies of horses, have been so termed by old writers on the veterinary art.

ANGLING. Notwithstanding the many sarcasms that have been thrown out by a variety of authors against the practice of angling, there are a number of circumstances, independent of the natural predilection which many evince, that concur to render the diversion more extensively practised than most others: requiring neither

qualification nor license, the angler is less liable to be informed against, even should he commit a trespass, than the shooter, whilst the number of *free waters* enables him to choose those situations where he is in no danger of being annoyed: the delightful season of the year is another inducement; whilst it is at this time, that, "people being gone out of town," the London tradesmen and shop-keepers are enabled to spare a little time for angling, which they could but ill afford during the winter season. Angling, indeed, has long been the particular amusement of the Londoners (perhaps because they could get no other); and it is this, together with the superiority of their tackle, and the comparative scarcity and shyness of the fish in the waters frequented by them, that renders the London angler much superior in point of skill to the provincial sportsmen, in every department except fly-fishing: here it is that the London angler fails, through want of practice, there being few really good trout streams near the metropolis, except those which are private property; whilst in Wales, the north of England, and Scotland, every brook literally swarms with these fish, affording to the inhabitant of those parts continual practice of the best kind, no fish living so exclusively on flies during the summer season as the trout, with the exception of the grayling or umber, a fish remarkably scarce in the south.

The first thing to be attended to by the angler is the necessary apparatus, consisting of rods, lines, winches, float, hooks, landing rod, landing net, plummets, baiting needles, disgorgers, clearing ring, drag hook, split shot, two or three leger leads, a pair of pliers for putting shot on a line, caps for float, kettle for live bait, a pannier or basket for ground bait, gentle-boxes, bag for worms, a piece of Indian rubber, bank runners, cork or man of war trimmer, thumb winder, book of trolling tackle, books of flies with materials for making them, a piece of shoemaker's wax and a bit of soft leather; also, a pocket-book of fishing tackle, with a reel to hold lines.

THE ROD. As the angle-rod is a material article in the angler's catalogue, much care should be taken to procure a good one. The fishing-tackle shops keep a great variety, made of bamboo cane, hazel, hickory, &c. and of different lengths; some fitted as walking canes, and others to pack in canvas bags: the latter are to be preferred, because you may have them

of any length, and they are made more true, and are stronger: the rods made to pass for walking-canes seldom exceed twelve feet, which is, generally speaking, too short: those made of bamboo cane are best for general fishing, having several tops of various strengths; but the rods made of the white cane are much superior for fine fishing, particularly for roach, being very light in weight, but stiff. In choosing a rod, observe that it is perfectly straight when all the joints are put together, and that it gradually tapers from the butt to the top, and is eighteen feet long; if longer, they seldom play true;—some strong, and fit for trolling; others for barbel, perch, &c. and some finer, for roach, &c. all of which should have rings in every joint. Rods fitted with several tops, all packing together, are certainly very convenient, when on a distant journey; but the angler who wishes to have rods neat, and to be depended on, must keep one for trolling; another for barbel, perch, or other heavy fish; and also a fine light cane rod, for roach and small fish, as well as those for fly-fishing. A good trolling-rod should be made of the choicest stout and well-seasoned bamboo cane; in length, it should not be shorter than fourteen feet; but sixteen is more desirable, if your tackle-maker can furnish cane every way fit for the purpose of striking true, and not too heavy, yet sufficiently strong; but if bamboo of a sufficient length, &c. is not to be procured, the tackle-makers use other light wood for the butt, generally well-seasoned willow: those anglers who are indifferent about the weight of a rod, may have them made of solid wood, in four joints, each measuring nearly a yard and half: such trolling-rods will almost last for ever. When trolling with the gorge or live-bait fishing, a long rod is necessary to enable the angler to drop in his baited hook over high sags, rushes, &c.; and also if the water be bright, he should then keep as far away from it as he possibly can, which a long rod enables him to do while dipping, casting or spinning his bait; for, if either a jack or pike see him, it is very rare indeed that he will then take the bait: and again, with a long rod you will be able to drop your baited hook in some very likely place for jack or pike to lay, such as a small hole, division, or clear place among a bed of weeds, in a river, or any other water where there are many weeds; but if your rod be too short for that purpose, your baited hook frequently falls short when cast, or among the weeds, in-

stead of the open place which you desire or wish it to fall into: in such case jack or pike are alarmed, and your chance of getting a run (a run in jack and pike-fishing is a bite) is lost; and frequently the bait is spoiled, or much injured, by catching or hanging to the weeds: you then have to bait your hook afresh, losing time, &c.—from which mishaps you are, perchance, sometimes near losing your temper, forgetting that hope and patience support the fisherman. There is some difference of opinion among anglers about the number of rings necessary for trolling-rods; those who have their line on a thumb-winder, or on a bank-runner, seldom place more than two or three rings on their rod, and others have only one large ring at the top; but if a winch is used, there should be a ring to every joint except the butt; that is, fasten the winch to the butt about a foot from the bottom, and let that joint be without a ring, and all the other joints except the top to have a ring, each made of double brass wire, fixed so as always to stand out, and nearly large enough to admit the top of your little finger; the top joint should have two rings, the top one nearly three times the size of the others: this prevents any obstruction to the line running, which is of material consequence. I have two tops to my trolling-rod, which I always carry with me, in case of breaking one, &c.: one is made very flexible, with wood, and a whale-bone tip about two feet long: to this, for strength and security, I have a ring on the wood part, as well as the large one at the whale-bone tip: this top I always use when trolling with the gorge bait, or when fishing with the live bait: the other top is made wholly of stout whale-bone, about one foot long; this I only use when snap-fishing, which it is well calculated for by its superior strength and stiffness. Those anglers who may object to have such large rings as I have described fastened on their rods so as always to stand out, instead of laying close to the rod, because they prevent the several joints packing one within another, and in consequence augment the bulk to be carried going to and from trolling, can have such rings, if they prefer them to those which lay close, fixed to metal ferules, made to fit each joint of the rod, which they may carry in their pocket, and put them on or off at the commencement and leaving off trolling or jack-fishing, excepting the top joint, which, with the rings on, will pack in the butt or largest joint of the trolling-rod; or, by using

such rings and ferrels, a roach rod may be used for trolling, leaving out the weak top joint; some anglers use a few small brass curtain rings sewed to loops of leather, and pass the loop over each joint of a stout walking cane rod, made with long joints and without rings; the hanging outwards through which rings the trolling line runs: these leather loops are made in a similar manner to those which you may see in the fishing tackle shops, passed over as the means of keeping together several joints of hazel and other common fishing rods: some few anglers troll without a rod, only using a poll, or a stick with a forked top; they carry their line on a bank runner, or a hand winder; after baiting the hook and letting out a proper length of line, they then pass the fork of the stick or poll under the line about a yard above the baited hook, and cast out in search, and occasionally use the said fork, to hoist the line over, &c. the high sags, rushes, or whatever else may impede their progress. This mode of jack or pike fishing can be resorted to by an angler who may be at a water which promises sport, and he, unfortunately, is without a proper rod; unless this happens, I think few anglers would so troll or fish for jack or pike.

If you should have the misfortune to break your rod while fishing, repair it in the following manner:—cut the broken ends with a slope, so that they may lay smooth and close together, then bind them together with some strong silk or twine waxed with shoemaker's wax, or you may use wax ends such as cobblers mend shoes with; begin to bind the fractured parts together about two inches above the middle of the fracture, then whip or bind back again to the part at which you began; now bind or whip down again, keeping the lapping close together until you come within four or five turns of the two inches below the middle of the fracture; now lay the forefingers of your left hand over the rods, then with your right hand make four or five bows or hoops over the finger of your left hand with the silk, or whatever you are mending the rod with, and pass the end of it between the under side of your left hand finger and the rod; now draw away gradually your left hand finger, and with your right hand finger and thumb take hold of the second from the top of the bows or hoops, and draw it tight, which will make the first bow or hoop lay close and secure over the broken rod; then draw the third, which will secure the second from breaking, and so on till all lays

smooth and close to the last turn; to fasten and fix which, take the end of the waxed silk or twine which lays under the bows or hoops just described, and draw it upwards till all lays smooth and tight; then cut off the spare part, and all will be fast and strong. This way of mending and fastening off, without tying, is called the hidden or invisible knot. If you mend a broken rod at home, spread a little softened shoemaker's wax on each slope of the broken rod, or glue them before you attempt to bind these sloping parts together, and it will increase the security of the broken parts; after which, varnish the whipping and lay them to dry, which will soon take place if good drying varnish is used. When you have occasion to mend a small joint of a rod, then a bodkin or a disgorging does not require that the hooped whipping should be so large as if passed over the finger, and in consequence thereof, are, with less difficulty, drawn and confined to their proper places: when the bodkin or disgorging is used, you pass the waxed silk or twine through the eye of either of those instruments, which enables you to draw from under those bows or hoops, before described. This is the best way I can describe or direct the angler how to repair a broken rod; for, when at a distance from home, &c. he should be prepared to remedy such an accident.

**LINES.** Fishing lines are made of gut-twisted horse or cow hair, and single horse hair, also of silk and mohair, or of silk alone, either twisted or platted; those made of gut are the strongest, the twisted hair cheapest, and the single horse hair the finest: you may make a fine line having half single hair at bottom, the other part, two hairs twisted: the gut or silk-worm gut is made or manufactured from the intestines or gut of the silk-worm, and is the strongest substance, for its circumference, known by the angler, and makes a line superior to any thing else; the natural colour of which is better than much that is stained. The young angler will find a line of about four yards in length the most useful either to fish with or without a winch, as he must note that the line is unmanageable if longer than the rod: in shotting the line to sink the float, place them close together within three inches of the bottom loop of the line, to which loop fix the loop of the hair or gut that the hook is tied to, and always put one or two shot on them, above the middle, which will keep your bait down, and cause the whole to swim steady: how-

ever, when you make a line either of silk, gut, or hair, it always must be finest at bottom where the hook is fastened,—very gradually increasing in bulk or thickness to the top. Note, when you place shot on the line, do it with a pair of pliers, which is the best and easiest method; some fasten them with their teeth, but it is a bad practice, for they often bite the hair or gut through, which causes much delay and vexation, particularly if it happens when you are fishing. Many good fish are lost after they have been fairly hooked, by the hook breaking or straightening; therefore make it a rule to try the strength of your hooks before you tie them on, or use them, in the following manner:—hold the hook by the shank, and place the other end over a nail or staple that may be driven in a board, wall, or any other place, then pull strong with jerking: if the hook breaks, there is an end of the trial; if it bends a little and again recovers its shape, it may be used; but if it bends or nearly draws straight, it should be rejected, for you are as likely to lose a fish by the hook straightening as by its breaking: a real well-tempered hook will neither bend nor break: small hooks may be tried by holding one between the fore finger and thumb of each hand, by their shanks, and hooking the bended parts together, and pulling and jerking one against the other. Some anglers tie the line and the length which is fastened to the hook, together, instead of using loops, which is a neat way. Note, those who choose to twist their own lines may purchase machines for that purpose at all the principal fishing tackle shops, and receive information how to use them. In respect to the advantage arising from angling with lines made of single horse hair, and hooks tied to the same over those which are made of fine gut, some difference of opinion exists among anglers, the advocates for gut say, when it is equally fine and of the same colour as horse hair, it is not likely to alarm fish any more than horse hair, and being much stronger, it certainly deserves the preference. This seems plausible, but I know from practice, that fish may be taken, when angling, with a single hair line (especially roach) that will not touch the bait when offered with a gut line, though the line shall be as fine and of the same colour, &c. as the hair line. To ascertain the fact, I have several times taken off my hair line, when roach have been well on the feed, and put on one of gut; I could then hardly take a fish; again I changed for the hair line,

and had excellent sport:—such has invariably been the case with me, and many experienced anglers of my acquaintance; therefore, I should certainly recommend single hair to those who fish for roach, dace, bleak, and gudgeon; and assert, without fear of contradiction, they will kill nearly two to one to those who angle with gut, however fine; the only reason I can assign for this difference is, that gut ever retains a shining glossy appearance in the water; and also small beads or bladders of water hang around the gut, which increases its bulk while in the water, and probably creates alarm among fish. Trolling lines are made of silk, and also of silk and hair or mohair, of various lengths and strengths, by platting, spinning, or twisting several strands together. There are silk lines called India twist, sold at the fishing tackle shops, and at some of the china shops, and other shops in London. This India twist may be bought of any length and degree of strength and fineness, at something less per yard than what is manufactured in this country; but it is much inferior in strength and value, because it is full of gum when you first purchase it; and after some little wear and tear, the gum is gone, the line then soon untwists and becomes rotten, therefore very unfit for jack and pike fishing. The platted silk lines are the best for trolling, in every sense of the word; they are stronger than those which are twisted. Let the twisted be made wholly of silk, or silk and hair, or mohair. Platted silk lines are also less inclined to link or tangle, than the twisted, which every troller knows, is of some consequence. Therefore, my advice is to provide yourself with a platted silk line, the colour immaterial, made of about eight strands, and in length, from fifty to sixty yards. If you wish to make your line waterproof, dress it in the following manner:—lay the line in coils, in a large tumbler or basin, and pour as much cold drawn double boiled linseed oil on it as will cover the whole, let it lie a few minutes, then take the end last put in, and gradually draw all the line out of the tumbler or basin, and pass it through, or wipe it with a piece of woollen cloth or flannel, which will make the surface smooth, and the whole line will be alike saturated with the oil. Hang the line up, for a few days, in dry air, and it will then be fit for use. Note, some trollers think this dressing a line causes it sooner to rot; but I am not of that opinion; I find a line so dressed, is less likely

to tangle, or stick to the rod, than those without it; and, also, that the dressed line passes quicker through the rings when you make a cast, in consequence of its not imbibing much water, and from its being a little stiff.

**TO FASTEN THE ROD TO THE LINE.** Pass the loop of your line through the ring at the extremity of the top joint of your rod, carry it over the ferrule end, and then draw your line up to the top again; the loop will then be fast, and the line will hang from the above mentioned ring: you will then put the joints of your rod together, and the rod and line will be complete. Most experienced anglers keep about six or eight inches of fine silk line tied to the end of the top joint, and fasten the gut or hair line to the said six or eight inches of silk, by a draw loop knot; this is an excellent method, because the ring is apt to chafe gut or hair. When you have a winch on your rod to use running line, pass the said running line from the winch, through every ring on the rod, and pull about a yard of it through the top ring and fasten it with a draw loop knot to the line which has the float and hook to it: when you angle with running line for those fish that it is proper to strike the instant you perceive a bite, make a slip knot in the line, and put in the said knot a piece of thin stick, quill, or tough grass, about an inch long, to prevent the line running back on the rod, which it will do, especially if the wind is any way in your front; and by their hanging slack on the rod, prevents the hook from fixing firmly in the fish you strike: always keep your winch unlocked, because in the hurry of the moment, when you have struck a heavy fish, and the winch is locked, he generally breaks away before you can give line to prevent such an occurrence. I use only those winches which are made without locks or stops.

**WINCHES.** The best winches are those that fix in a groove, and are fastened with brass ferrules, made for the purpose, on the butt; because you can fasten such a winch to any sized joint; which is not the case with those with a hoop and a screw. Be sure to choose a multiplying winch, which will be found infinitely superior to a common one.

**FLOATS.** With regard to floats, it is of the first consequence that the angler should be acquainted with the floats proper for fishing in different waters, and for various kinds of fish; as more depends upon that part of his tackle, than inexperienced

or superficial observers imagine. I shall therefore request his attention while I point out those proper for the purpose:—

**THE TIP CAPPED FLOAT.** These floats are made of several pieces of quills, or of reed for the middle, and ivory or tortoise-shell at the top and bottom, and narrow at each end, gradually increasing in bulk or circumference to the middle; but those which are made thickest above the middle, nearest the top, I find, swim the steadiest, in blowing weather, against the stream, rough eddies, and at the tail of mills: these floats are fastened to the line with a cap at each end. Tip capped floats are superior to every other for angling in waters which are not very rapid, particularly in roach fishing, as the least movement or fine bite sinks it below the surface of the water. The tip capped float is also best for pond fishing for carp and tench; as it requires but few shot to sink, it consequently disturbs the water but little when cast in; which is of the first consideration, when angling for such shy or timid fish as carp, tench, or chub. Note, the caps which fix the line to the float are often rough at the edge, which chafes and weakens a fine line; therefore, make it a practice to examine and smooth them before you put them to use.

**CORK FLOATS** are generally made of quills at the top, with a piece of cork which is burned or bored through the middle, to admit the quill, and then filed or ground smooth, and painted; the bottom is plugged with wood and a ring to let the line pass through. The cork floats are well calculated to fish in heavy and rapid streams, as they require a great many shot to sink them; which weight of shot prevents the baited hook passing too quickly over the bottom of the place where you may be fishing; for, with a strong current or stream and a light float, the baited hook goes over the place you have ground-baited, before it reaches the bottom; consequently you lose the greatest chance of success from the float not sinking quickly. Cork floats are made of various sizes and shapes: instead of common quills, some introduce the quill of the porcupine, which makes an excellent strong float.

**PLUGGED FLOATS.** These kind of floats are the cheapest, and made of indifferent quills; some of them with one goose quill and a wooden plug at the bottom, from which they take their name; they are very apt to loosen by the plug coming out. These floats suit the young angler from their cheapness, and by being easily put on the

line, having a cap at the top, and a ring at the bottom; however the better informed angler objects to the ring at bottom, because it does not keep the line close to the float, and from the resistance or hindrance it makes in passing through the water, particularly when the fish bite fine; therefore, he always uses the tip-capped float in ponds or rivers, where the stream will admit, in preference to every other.

**TO MAKE THE FLOAT STAND OR SWIM UPRIGHT IN THE WATER.** Some shot must be put on the line, as directed in the next article; they are kept ready split for the purpose, at the tackle shops. To strengthen a quill float, and to prevent the line slipping after passing the line through the bottom cap, give it two or three twists round the body of the float before you fix the top cap to it.

**TO TIE ON A HOOK.** Hold the hook between the thumb and finger of your left hand, and whip round the shank from the bend of the hook to the top, some fine silk waxed with shoemaker's wax, then lay the hair or gut on it, and whip it over very close with the waxed silk, from the top of the shank till you come opposite the point of the hook, then draw the silk through the loop which is made by leaving it three turns slack, and cut off the spare silk. The knot used in making fishing lines is called a water-knot, which is made by passing the ends twice over and then drawing them tight—this knot will never draw or slip. To wax the fine silk used in whipping or tying on hooks requires some care, therefore take the following directions:—Get a piece of stout leather, such as the upper part of shoes or boots are made of, and lay some shoemaker's wax of the softest sort smoothly on it; then take three or four lengths of silk together and draw them over the wax with one hand, keeping your thumb of the other hand lightly pressed on the silk, the waxed leather lying or resting on the fingers of the same hand, until the whole is well coated with wax; then take each piece separately and draw it briskly between a piece of soft or wash leather, by which friction every part of the silk will be equally waxed and then fit for use.—Note, fine silk is not strong enough to be waxed singly, and it is a saving way after having waxed several lengths of silk together and separated them, to fix every one singly with a pin to a cushion, such as are made to screw on the edge of a work table; those cushions are to be bought at any toy shop. Twine may be waxed in single

threads the same way as practised by shoemakers or menders.

To bait a hook with a worm use the following method:—first, enter the point of the hook close to the top of the worm's head, and carry it carefully down to within a quarter of an inch of its tail; to do which you must gently squeeze or work the worm up the hook with your left thumb and finger, while with the right you are gradually working the hook downwards; the small lively piece of the worm at the point of the hook moving about will entice or attract fish; but note, if too much of the worm hangs loose, though it may entice fish to nibble, yet they will seldom take the whole in their mouth so as to enable the angler to hook them; on the contrary, he is frequently tantalized with a bite, and when he strikes finds part of the worm gone, the hook bared, and no fish: therefore, to bait a hook well with a worm is necessary to insure hitting a fish when you strike, and it consists in drawing the worm, without injuring it, quite over and up the shank of the hook, leaving only a small lively part of the tail below the point thereof. If you bait with half or a piece of worm, prefer the tail end, and enter the point of the hook into the top part of it and bring it down nearly to the end of the tail, leaving only a very small piece loose. But if you bait with two worms on a hook, draw the first up above the shank while you put the second on in the same manner as directed with one worm, but enter the hook near the tail of the second worm, then draw the first one down on the second over the shank of the hook, and all will be then well covered, and will be a very enticing bait for perch, carp, chub, barbel, and all large fish; but when angling for gudgeon or other small fish, half a red worm is sufficient, and the tail end is best; if blood worms are used put on two or three, in doing which be very tender or you will burst them.

**WITH GENTLES.** To bait a hook with a gentle, use this method:—enter the point of the hook into the gentle near either end, and bring it out at the other end, then draw the point back again just within the gentle enough to hide it: if you use more than one pursue the same method. This is the best way to bait with a gentle whose skin is something tough, especially in cold weather, by piercing the skin in the first instance; with striking fine (when a bite) your hook will enter sufficiently into the fish and secure it, and you do not risk breaking your line or the top

of the rod, which frequently happens by striking too hard.

**WITH GREAVES.** To bait a hook with greaves is as follows:—first select the whitest pieces from what you have soaked, and put four or five pieces on your hook, or as much as will cover it from the bend to and over the point; these pieces should be about half the size of a sixpence and put on the hook separately or one after the other, not a large piece doubled, as some indolent anglers do, for then the hook is prevented entering firmly the fish you strike; whereas, by putting the pieces on separately, when you strike they either break off or are pushed up the shank, and the whole bend of the hook enters the fish, and you have firm hold. These minutiae of baiting, &c. are of singular advantage, which the observing angler will not fail to attend to and appreciate, being worthy of his notice. Note: it is a bad practice to boil greaves or soak them in boiling water, for it makes them rotten and soon fall off the hook: they are longer in soaking in cold or cool water, but are then tough.

**LANDING HOOK AND LANDING NET.**—The landing hook is a large hook which is sometimes barbed like a fish hook and sometimes plain, fastened on the end of a rod; this rod is occasionally composed of several pieces which run one within another like a telescope, from which the apparatus is called a telescope handled landing hook. A landing net is small like a purse net, mounted on an iron ring, which is fastened like the landing hook on the end of a rod or pole.

**PLUMMET.** Plummetts are of two kinds, either the common plummet, or the folding plummet.

**PLUMMING THE DEPTH** is done in the following manner:—if a ring plummet, pass the hook through the end, fix the point into the cork at the bottom; if a folding plummet, unfold about two inches of it, pass the hook over its side, and then fold the plummet up again; your hook is now secured from drawing away from the plummet: as success depends much in angling at a proper depth, take due pains, and measure the depth accordingly before you begin fishing. Note: when the plumb lead touches the bottom, and the top of the float is even with the surface of the water you have the true depth.

**BAITING NEEDLE.** The baiting needle, for putting on dead baits for trolling, &c.

**DISGORGER.** The disgorging is an instrument with a forked top about six

inches long, made of bone, iron, or brass. When the fish has swallowed the hook, the forked end of the disgorging is thrust down upon it with one hand, while you hold the line tight with the other, which disengages the hook, and permits it to be easily drawn out. This is the safest way to unhook a fish that has gorged the bait, or got the hook fixed in its throat, because by using violence with the thumb and finger to disengage it, you sometimes break a fine or small hook either at the point, barb, or shank, which causes loss of time and much vexation, in having another hook to put on, to plumb the depth again, &c. which is all absolutely necessary to be done, or you may as well give over fishing. But when the fish is hooked through the lip, the angler has only to hold the fish steadily in one hand while with the other he carefully takes away the hook.

**CLEARING RING—CLEARING LINE.**—The clearing line is made of several yards of strong small cord, to the end of which is fastened a heavy ring of lead or brass; if the hook should get fast to a heavy weed, post, or any thing else, this ring is put over the rod and suffered to go down to the hook: hold the rod in your right hand, the top pointing downwards, and the clearing line in your left, letting the ring fall on the hook, which, from its weight, generally clears the hook from what it may have struck into: if not, hold the rod tight, and draw the line sideways and break away. In this case the angler seldom loses more than a hook, if he acts as above directed, but without the assistance of a clearing ring he frequently loses his float as well as hook and line, and sometimes breaks his top joint. The brass clearing rings are to be preferred, because they are jointed, and in consequence can be used when the angler has a winch in his rod, in which case the leaden ring could not be passed over the winch.—These useful articles to the angler are to be met with at the fishing tackle shops.

**DRAG HOOK.** The drag is a piece of iron with three or four stout wire hooks, without barbs, placed back to back, to which is fastened a long packthread line; this is used to draw away weeds that a heavy fish may have got himself or the line among, and also to recover any part of the tackle that may be entangled in weeds, or to take up night lines, trimmers, &c.

**LIVE BAIT KETTLE.** With regard to the live bait kettle, I prefer one of a long

square form to a round one, and have always mine japanned white inside and brown out, as the water is much less agitated in such a shaped kettle when you are carrying it than in a round one, and it is more convenient to carry or pack in a basket, &c. for a journey. To select my bait, instead of putting my hand among the fish, which not only frightens them, but by heating the water, makes them sickly and dull, I make use of a very small net, not much more than half the size of those used to take gold and silver fish out of globes; this net I carry very conveniently in my fish kettle, by having a piece of the lid cut away at one corner, where a few inches of the handle of the net projects.

**INDIAN RUBBER** is of use to rub lines when they become chafed and ragged, as it immediately makes them smooth; by rubbing gut or hair, which has laid in coils, with Indian rubber, it will instantly become straight.

**BANK RUNNER.** The bank runner is mostly used in the day time while the angler is fishing for roach, barbel, &c. and is stuck in the bank, the bottom being strong turned wood sharpened for the purpose, with a winder at top for the line, which should be from sixteen to twenty feet long, made of silk trolling line, thin cord, or platted Dutch twine; but you must have a cork and bullet to the line, and bait with a live fish, which should swim a foot or two from the ground, as it will by the aid of the cork.

When you use the rod, hold the line with your left hand, and with your right pass the forked end under the line just above the bullet; you may then place the baited hook in the water where you please by a jerk of the rod; at the same time letting the line go from the left hand.

**MAN OF WAR TRIMMER**, called also a foxhound, is made of a large piece of flat cork, about five or six inches in diameter, with a groove to admit the line, which is the same as that used for the bank runner; it is, however, without a cork, and sometimes without a bullet, according to circumstances.

The hook is baited with a gudgeon, roach, or some small fish; you then draw as much line out as admits the bait to hang about a foot from the bottom. There is a small slit in the cork or in the peg which is sometimes thrust through it, that you pass the line in to prevent its unwinding; as soon as a fish seizes the bait,

the line loosens and runs from the groove of the cork freely, and allows the fish to return to his haunt and paunch at leisure.

**THUMB WINDER.** Thumb winders are sometimes used instead of winches, but they are extremely inconvenient.

**ANGUELLES.** Small worms thrown up by sick hawks.

**ANIMAL.** All bodies endowed with life and with spontaneous motion are called animals. Hence are animals distinguished in general from vegetables. But this gives us no perfect definition; for there are entire classes of animals which are fixed to a place; as the lythophytes, and zoophytes, which are produced and die upon the same spot; and, on the other hand, certain vegetables have as much motion in their leaves and flowers as certain animals; for example, shell-worms. However, by attending to the most general characters, we may define animals to be bodies endued with sensation and motion, necessary to preserve their life. They are all capable of reproducing their like: some, by the union of the two sexes, produce small living creatures; others lay eggs, which require a due temperature to produce young: and some multiply without a conjunction of sexes.

**ANISEEDS.** This seed is much used as a stimulant and cordial in horse medicine. When reduced to powder, it forms a principal ingredient in the formation of the pectoral cordial-balls for horses; they are generally mixed with ginger, caraway-seeds, &c. They yield by expression an aromatic essential oil, which contains all the medical virtues of the seeds. When the oil is used, the dose is about half-a-drachm, which may be given in warm ale, rubbed down in a mortar with sugar.

**ANODYNES.** Medicines that alleviate or remove pain, the principal of which is opium. Hemlock, deadly nightshade, henbane, and belladonna, possess also anodyne qualities, but are much less certain in their effect than opium. When pain depends upon spasm, as in the flatulent or spasmodic colic, which is commonly called gripes or fret in horses, these are excellent remedies. But pain often depends on inflammation or obstruction in the bowels or other passages; and in such cases anodynes or narcotics are injurious, and should never be given to the horse. Anodyne fomentations are sometimes used, which consist chiefly of a decoction of white poppy-heads.

**ANTÆUS**, bay, bred by Mr. Cornforth, 1789, got by Phlegon out of Jacintha by Cornforth's Forester, out of bay Babra-

ham, the dam of Johnny. In 1793, he won £50 at Newcastle; 1794, the King's plates at Newcastle and York. Antæus was sire of Wrestler, &c.; he was sent to Russia.

**ANTELOPE.** The different species of this animal, which are all included under one general name, are chiefly found in the hottest parts of the world. Like the goat tribes, antelopes have hollow horns, which they never shed, forming, thereby, a strong mark of distinction between them and the deer tribe, which they greatly resemble in the elegance of their form and the swiftness of their motions.

Of all animals, the antelope, or as it is called in the east, the gazelle, has the most beautiful eye; and the oriental poets continually compare the eyes of the ladies they wish to celebrate, with the eyes of this animal.

Antelopes are generally found in large herds, sometimes amounting to two or three thousand, preferring hilly countries; and such is their extraordinary swiftness, that the fleetest greyhounds are unequal to the chase.

Mr. Johnson, in his Sketches of the field sports practised by the natives of India, gives the following method of taking antelopes with the *cheetah*, or hunting leopard. "It is distressing to see them (*the cheetahs*) catch the deer; they are led out in chains, with blinds over their eyes; and sometimes they are carried out in carts; and whenever antelopes, or other deer, are seen on a plain, should any one of them be separated from the rest, the *cheetah's* head is brought to face it, the blinds removed, and the chain taken off.

"He immediately crouches, and creeps along, with his belly almost touching the ground, until he gets within a short distance of the deer, who, although seeing him approach, appears fascinated, and seldom attempts to run away. The *cheetah* then makes a few surprising springs, and seizes him by the neck. If many deer are near each other, they often escape by flight, their numbers, I imagine, giving them confidence, and preventing their feeling the full force of that fascination, which, to a single deer, produces a sort of panic, and appears to divest him of the power, or even inclination, to run away or make any resistance. It is clear that they must always catch them by stealth, or in the manner I have described, for they are not so swift even as common deer.

"Antelopes are the swiftest of all deer. The keeper carries with him some carrion, commonly bullock's liver, which he gives the *cheetahs* when they have caught a deer, to induce them to surrender it. They are then allowed to satisfy their hunger, and are again blinded and chained. I believe they seldom, if ever, kill more than one deer with each *cheetah* on the same day. Two are often loosened after the same deer, but more frequently after two, or a herd."

Among the Persians, falcons are trained up to hunt the antelope, having the stuffed skin or figure of that animal, on whose nose they constantly feed the falcons. Having spied an antelope, they let fly two of these falcons, one of which fastens just upon the nose of the creature, who endeavours to shake off his enemy, whilst the bird flutters to keep his hold, which hinders the antelope from seeing well before him. If, however, he happens to disengage himself from his first assailant, the other falcon immediately stoops, and supplies his place, whilst the one that the antelope has thrown off hovers over him, ready to fill his companion's place, should the animal get rid of him also. In this manner they harass the poor creature, and impede its running, till the dogs overtake it.

**ANTELOPE** was got by Croft's Brilliant, dam by Bumper, grandam by a son of Bartlett's Childers, great-grandam by the Chesnut Litton Arabian, great-great-grandam by King William's white Barb called Chillaby, great-great-great-grandam by the Byerley Turk, out of the Farmer mare. Antelope, at three years old, won a match at Epsom; at four years, he won the four-year-old plate at Canterbury; at five years, he won the King's plates at Burford and Lichfield; at six years, the King's plates at Guildford, Winchester, Lewes, and Salisbury; at seven, he beat Mr. Croft's Tortoise, giving him 14 lbs., at Oxford. Antelope was foaled in 1760; he was fifteen hands and a half high; he covered at Newmarket at three guineas.

**ANTHELMINTICS.** Those medicines which remove or destroy worms of the intestines are so called. Both the stomach and intestines of horses are liable to be infested with different kinds of worms; for these the same plan of treatment is proper, whatever kind of worms they may be. Mercurial purgatives are the most certain anthelmintics. Oil of turpentine has been recommended as an

anthelmintic, and has been found very efficacious.

**ANTICOR.** A disease of the horse, very differently described by various authors; indeed, they seem to have applied the name to different diseases. They all seem to agree in the propriety of bleeding the horse freely, and giving opening medicine. "It is known," says Solleysel, "by a swelling in the breast just opposite to the heart, from whence the word anticor (anticœur) is derived."

**ANTIDOTE.** Those medicines that destroy or prevent the effects of poison are so called. When a horse has been maliciously poisoned by arsenic, or corrosive sublimate, a solution of soap in some mucilaginous fluid, such as infusion of linseed, should be given freely; oil and salt of tartar are recommended also, and the sulphuret of potash.

**ANTIEN PISTOL,** bay, bred by Lord Grosvenor in 1764, got by Snap out of Eloisa, by Regulus; grandam (own sister to the grandam of Elfrida) by Bartlett's Childers. In 1769, Antient Pistol won the 1200 guineas sweepstakes, at Newmarket: in 1770, his lordship disposed of him to Mr. Parker, in whose possession he was a winner of 150 guineas and £50 at Wells, and £50 at Bath. Antient Pistol covered in Devonshire at ten guineas; he was sire of Cinder-Wench, Nannette, Yarico, Pistol, Arbitrator, Index, Reptile, Allegrante, Lucifer, Culverin, Milo, Hardwicke, Squib, Julat, Old-Port, &c. &c.

**ANTIMONY.** A medicine much used in farriery. The term antimony was formerly given to an ore, in which antimony was combined with sulphur; but it is now solely appropriated to express the pure metal. It is found in various parts of the world in different states of combination. There are several preparations of antimony, the most useful of which are the tartarized antimony or tartar emetic, antimonial powder, and the sulphuret of antimony. Tartarized antimony is preferable to every other preparation, as a fever medicine; and though it is a strong emetic in the human stomach, yet it does not even appear to excite nausea or sickness in the horse; it is with that animal a safe and effectual fever medicine, in doses of from one to two or three drachms. Butter of antimony, now called muriate of antimony, is a fluid preparation, which is often employed as a caustic in foul ulcers, such as canker, quittor, and farcy buds. The sulphuret of antimony is given to the

horse as an alterative, to improve the coat and condition. The common dose is an ounce or more.

**ANTINOUS,** chesnut, bred by the Duke of Grafton, in 1758, was got by Blank, dam (sister to the Widdrington mare) by Partner; grandam by Bloody Buttocks. In 1762, Antinous won the King's plate at Ipswich: in 1763, a sweepstakes of 1200 guineas at Newmarket: in 1764, Antinous beat the Duke of Cumberland's Gift over the B. C. 600 guineas, and received 50 guineas forfeit from Mr. Pratt: 1765, he won 500 guineas, beating Sir John Moore's Fryar, Newmarket B. C.; and the great subscription at York, beating Le Sang, Engineer, and three others: 1766, a sweepstakes of 1500 guineas, at Newmarket, beating Askham and Prospero; at starting, three to one on Askham; 1767, thrice 500 guineas at Newmarket. Antinous covered at Euston, at ten guineas; he was sire of Euston, Hylas, Skipjack, Abelard, Duke, Sweet-William, Tickler, Leap-Frog, Tell-Tale, Duchess, Nun, Searcher, &c. &c.

**ANTIPHLOGISTICS.** This term is applied to those medicines that cure inflammatory complaints, to which almost all the diseases of the horse are allied; it signifies also any general mode of treatment or regimen, that is calculated to cure inflammation. Antiphlogistic remedies, properly so called, are divided into general, by which are meant such as affect the whole system, and into topical, the operation of which is, at least for a certain time, entirely local and circumscribed.

**ANTISEPTICS.** Remedies supposed to have the virtue of resisting the tendency to putrefaction. The most efficacious in veterinary practice are bark, opium, camphor, ammonia, wine, and yeast. As external applications in gangrene or mortification, the fermenting poultice, and the common poultice with powdered charcoal sprinkled over it, have been very strongly recommended by some of our best authorities.

**ANTISPASMODICS** are medicines which possess the power of curing those diseases which depend upon spasmodic or convulsive action of any part of the body; of these, locked jaw is one of the most formidable. Opium, musk, camphor, and all the vegetable narcotics, have been given to the horse as antispasmodics. The spasmodic complaint to which horses are most liable, is the flatulent colic, commonly called fret or gripes, in which opium is the most useful remedy; it is generally

combined with other medicines, as assa-fœtida, camphor, the oil of peppermint, juniper, &c. &c., and is most efficacious in the form of a tincture, made by infusing the ingredients you use in proof spirits of wine.

ANTLERS, now generally understood to be the entire horns of either the red or fallow deer, was formerly applied to the *starts* or *branches* of a deer's horn, being divided into *brow antler*, which was the branch next the head, and *bes antler*, which signified the one immediately above the *brow antler*.

ANVIL, by Herod, dam by Feather, grandam by Lath, great-grandam by Childers. In 1781, at Newmarket second spring meeting, he beat Rosemary, R. M. 100 guineas; same meeting he beat Tetotum, R. M. 100 guineas; at Epsom he won the Ladies' plate; at Exeter, the great subscription for all ages (33 subscribers); and walked over for an all-aged sweepstakes at Bath. At Newmarket, 1782, first spring meeting, Anvil won £50, beating Boudron and four others; at Exeter he won the great subscription for all ages; at Blandford he won £50, beating Sulphur and three others. At Newmarket first spring meeting, 1783, he beat Buccaneer, B. C., 200 guineas; in the second spring meeting he won a sweepstakes of 200 guineas B. C., beating Boxer and Pot-8-os; he won the King's plate at Winchester, beating Mercury and Diomed, and next day walked over for an all-aged sweepstakes (seven subscribers); at Newmarket second October meeting, he won the whip and 600 guineas, beating Guildford and Boudron, 10 stone each, B. C. In the second spring meeting, 1784, at Newmarket, he beat Mercury, B. C. 300 guineas: in the second October meeting he won 60 guineas for all ages, D. I., beating Drone, Fortitude, and two others. At Newmarket, 1785, first spring meeting, he received 90 guineas compromise from Buzaglo, A. F. 200 guineas half-forfeit; in the same meeting he received forfeit from Premier and Cantator, D. I. 200 guineas half-forfeit; in the second spring meeting, carrying 8 st. 11 lbs., he beat Challenger, 7 st. 10 lbs. B. C. 200 guineas; in the first October meeting, he received forfeit from Signor, B. C. 200 guineas half-forfeit. Anvil was sire of St. George, Cymbeline, Mother Blackcap, Anvilina, Lisette, Sledge, Mother Shipton, Scotilla, &c. &c. He covered at Cannons, at ten guineas.

APERIENTS are medicines which mildly empty the intestines of their con-

tents, without producing the strong and repeated effects of physic given with an intention to purge. Small doses of aloes, the olive or linseed oil, neutral salts, as Epsom or Glauber's salts, are the medicines generally employed by the veterinary practitioner for this purpose.

APOLLO, bay, was bred by C. Routh, Esq., 1755, who sold him to Mr. Shafto. Apollo was got by Regulus, dam by Cottingham, grandam by Snake, great-grandam by the bald galloway. At four years old he won the great sweepstakes at Huntingdon; at five he beat the Duke of Cumberland's Dapper, for 500 guineas, won £50 at Ipswich and Huntingdon, and the King's plate at Burford; at six years he won the King's plates at Winchester, Salisbury, Lewes, Lincoln, and in the spring following at Newmarket. Apollo covered in Sussex at three guineas: he was fifteen hands high: he also ran and covered in Ireland.

APOPLEXY, in horses, is a paralytic affection of the brain, in which the horse generally drops down suddenly without sense or motion, except a working of his flanks. It seems to be caused either by too much blood being sent to the brain, or by a rupture of a blood-vessel in that organ; and bleeding is, therefore, the most essential remedy, along with purging medicines.

APOSTHUME (in hawks). A disease in the head, attended with swellings, and which is occasioned by the heat of the head, and various ill humours. It may be discovered by the swelling of the eyes, by the moisture that issues from their ears, and by the bird's slothfulness; for the cure of which, give a pill of butter the size of a nut, well washed with rose-water, and mixed with honey of roses and fine sugar, for three or four mornings, when they have meat: they must be held on the fist till they have made one or two mutes; then take four drachms of the seed of rue, two drachms of hepatic aloes, and one scruple of saffron; reduce all to fine powder, and mix with honey of roses, and make into a pill, which must be given them: it will purge, and scour their heads. About two hours after, give them some good strong hot meat. When the nares of a hawk are stuffed up with filth, after a convenient scouring, take pepper and mustard-seed beaten to a fine powder, put it into a linen cloth, and steep it for some time in strong white-wine vinegar, of which put some drops upon her nares, and they will soon cleanse her head.

**APPETITE.** Want or loss of appetite may arise either from fatigue, from overwork, or it may be the consequence of disease or fever, or from a diseased state of the digestive organs of the horse. If it depend upon fatigue, rest, a cordial ball, and warm mash, will soon restore the stomach to its usual state. If it be the consequence of disease, the particular disease must be overcome before the horse can be expected to have his accustomed appetite. The treatment then will of course depend upon the nature of his complaint. Horses have sometimes an excessive or craving appetite; they will even eat their litter, besides an unusual quantity of whatever food is given to them. This may justly be considered a disease, and one of importance; for, unless restrained, it often causes incurable cough, roaring, broken wind, and many other diseases. A horse of this kind should wear a muzzle constantly, except when he is feeding; he should only be allowed a proper quantity of food, at first rather more than another horse; his allowance of water also should be moderate. The only medicines likely to be of any service in this case are purgatives.

**APPLEGARTH**, chesnut, bred by Mr. Lidderdale in 1795; got by Stride, out of Emma, by Telemachus; grandam, A-la-Grecque, by Regulus; great-grandam by Allworthy; great-great-grandam by the Bolton Starling; great-great-great-grandam, Dairy-Maid by Bloody-Buttocks; great-great-great-great-grandam, Bay Brockelsby by Old Partner; great-great-great-great-great-grandam, Brockelsby by Greyhound out of Brockelsby Betty. In 1798, Applegarth won £50 at Penrith; 1799, £50 at Catterick, the King's plate, and 50 guineas at Edinburgh; 1800, £50 at Newcastle, £50 at Morpeth, and the King's plate at Carlisle; 1801, £50 at Carlisle; 1802, the Maccaroni stakes at Newcastle, and the King's plate at Hamilton; 1803, 100 guineas at Ayr. Applegarth served mares afterwards in Berkshire at three guineas; his charge after the second season was five guineas.

**APPROACHING** (in wild fowl shooting) was a device employed, to approach such birds as frequent waters and marshy places, and which are, for the most part, very difficult to reach. Various means have been employed for the purpose, one of which was, three hoops tied together, all at proper distances, according to the height of the man who was to use the in-

strument, and having boughs tied all round it, and with cords to bear on his shoulders, so that the person was thus concealed by the boughs, and was able to approach till he came within gun-shot. The figure of a horse was also used for this purpose, as well as several other devices, all of which appear to be laid aside, and aquatic fowls are rather waited for by the shooter, than any approach made towards them. Thus as it is very well known, that geese, ducks, teal, &c. leave the water, and fly to feed both morning and evening, the fowler places himself in a situation where he expects them to pass, and shoots as often as an opportunity offers. It sometimes happens that ten or a dozen shots will be presented in the course of an evening. Moonlight nights are of course the best for this amusement, as the birds continue to fly for some time after night-fall, and the diversion is consequently prolonged. Men well practised in this nocturnal shooting frequently become very dexterous, and will kill birds by moonlight with tolerable certainty; and even when the nights are quite dark, they will direct their aim by the sound of the bird's wings, and frequently effect their object. This, however, is a department of the chase very little attended to by sportsmen, as it is very chilly diversion, after all, and is principally followed by the peasantry who reside on the borders of the lakes and marshes, and obtain a precarious livelihood by it. But these fowlers resort to other modes of procuring their game, and by means of snares contrive to catch more than they are able to shoot with the gun. In very severe and long frosts, when the lakes and marshes are frozen, and aquatic birds resort to the larger rivers, they may be successfully approached by concealment in any manner, so as to resemble objects which are constantly passing before their eyes. Thus, on the River Dee, during the severe winter of 1822-3, a person so contrived a small boat in which he concealed himself, as to represent the floating ice and snow that was continually passing down the river. In this vehicle he also contrived to mount an enormous fowling-piece, by which, on approaching a flock of ducks, he was able to kill from a dozen to a score at one discharge.

**APRIL.** The month of April is extremely dull in regard to every branch of field-sports, except angling and otter-hunting, which latter generally begins this month. The various occurrences, &c.

## A P R

which may happen to be interesting to the sportsman in this month, we have attempted to arrange: the arrival of migratory birds, however, as well as other circumstances, will depend, in some degree, upon the forwardness or backwardness of the season. It is by observing the relation which one period bears to another that this arrangement will be found useful, as for instance—in about a week after you hear snipes piping and bleating, you may know that badgers have young; and that the stone curlew has arrived, when you see the house swallow, white throat, or redstart.

Fish for chub with red worms.

Fish for bleak, with small worms, paste, and gentles.

Otter hunting begins this month, if the weather be sufficiently warm.

Golden plovers resort to the high and heathy mountains of the north of England and of Scotland.

The pope and gudgeon spawn first time; bait with blood worms or gentles.

Badgers bring forth.

Dace spawn; fish with red worms, paste, or small flies.

During this month, martens, polecats, and other vermin of the weasel tribe, make considerable havoc among the game by destroying their eggs, or even the old birds, whilst sitting: these animals bring forth this month.

Fish for barbel with red worms, greaves, or gentles.

Curlews resort to the heathy, boggy, upland moors, where they breed, losing their fishy taste, and becoming well flavoured.

Pike not in season this month.

Godwits haunt the fens.

Rove for perch with brandling or minnow.

Stone curlew arrives; found on downs, sheep-walks, and dry stony places.

Fish for roach and rudd with worms, cad-bait, and gentles.

The house swallow, redstart, and white-throat, return.

Fish for carp and bream with red worms or blood worms.

Quails and land rails appear.

Bucks begin to shed their horns.

Begin to fish for tench; bait with blood worm or red worms.

The martin returns.

Fish for trout and grayling, with hackles, palmers, dark brown, bright brown, blue dun, whirling dun, cow dung, oak or ash fly, and horse fly; for trout with minnows or worms.

## A R C

Salmon now in season; fish with any large showy fly.

Fieldfare and redwing leave the country for the most part earlier.

Bitterns lay; also lapwings.

Foxes bring forth.

Hawks, crows, and magpies, may be readily destroyed, either by smearing bird lime round the nest, or by small pieces of poisoned meat.

The woodcock and royston crow depart, most of which leave this country at an earlier period.

Red grouse lay and sit, generally from eight to twelve eggs.

With this month gamekeepers should leave off breaking dogs, lest the birds be disturbed, and the breeding injured.

The roe (female of the roe-buck) fawns.

AQUATIC. That lives, breeds, or grows in or about the water, as *aquatic plants*, *aquatic birds*, &c.

AQUATICS. A term applied to any amusement or exercise on the water, as rowing, sailing, boat-races.

ARABIC, GUM, is given to horses, dissolved in water, in painful affections of the urinary organs, and to sheath and protect the bowels, when they have been disordered by too strong a dose of physic.

ARCHERY. Our ancestors used the bow for a double purpose; in time of war it was a dreadful instrument of slaughter; and in peace an object of amusement.—That both the anglo Saxons and the Danes were well acquainted with its use is certain, as the Scandinavian writers, when praising the heroes of their country enumerate among their acquirements a superiority of skill in handling the bow.—Among the Saxons and the Danes, however, it seems only to have been used for the purposes of food or pastime; and we are perhaps indebted to the Norman Conquest for its introduction as a military weapon.

The first thing to be learnt is to bend and unbend the bow, as it is sometimes broken by beginners who attempt to string it without having learnt the proper method. Before, however, we proceed in our directions for doing this, we must give a few definitions of the different parts of the bow.

The flat part of the bow is the *outside*, and is called the *back*.

The round part is the *inside*, and is called the *belly*. The two extremities of the bow are called the *horns*, the *longest*

ENGLISH

ARCHERY.

of which is at the *top* end of the bow, and the shortest at the *bottom*: the notches or grooves in the horns, and in which the string is placed, are called the *nocks*, being always spelt and pronounced that way in every thing relating to archery, and not notches. Remember that the round part or belly of the bow must always be bent inwards, for if you bend it the other way, that is, with the flat part or back inwards, it will instantly break.

**TO BEND OR STRING THE BOW.** To bend the bow you must take it by the *handle* and no other part (the handle is the centre of the bow, which is generally covered with cloth or silk shag), with the flat part or back towards you, the right wrist resting against your side, the lower end of the bow resting against the inside of the right foot, the toe of which ought to be turned a little inwards to prevent its slipping, the left foot being brought nearly a yard forward with the knee straight, though the knee of the right leg may be somewhat bent. You must now place the centre of the hand close to the wrist below the eye of the string, having the tip of the thumb on one edge of the bow, and the side of a knuckle of the fore finger on the other. When the hand is placed in the above position, pull up the bow briskly with the right hand, and press the upper part down with the left, sliding the wrist at the same time upwards towards the horn, till the eye of the string fall into the nock before the left hand is removed; take care and be certain that the string be well in the nock. Remember to press the finger and thumb somewhat firmly upon the edges of the bow, which will prevent the string from getting under them, a thing which often happens, and renders the stringing difficult.

Should the archer find himself not strong enough to bend his bow *alone*, he will, by the assistance of another person, be able to string it with ease, if that person places his finger on the top horn and bends it down whilst the archer carries the string upwards into the nock, holding the bow as before directed.

**TO UNSTRING OR UNBEND THE BOW.**—Hold the bow in the same position as before directed; press down the upper limb with the left hand, and slip the eye of the string out of the nock with the fore finger and thumb.

We must caution the archer to be careful that the string is not twisted round the bow, and that the noose be in the centre

of the horn, before he attempt to bend it: he should also see that when bent, the string runs along the centre of the bow, from the middle of one horn to the middle of the other.

To determine whether the bow has the right degree of bend, place the first finger perpendicularly on the inside of the handle of the bow, raising up the thumb as high as it will reach: if the string touches the extremity of the thumb, the bow is bent a proper degree.

Having now described the best methods of bending and unbending the bow, we shall proceed on our instructions in the practice of archery, which, according to Ascham, may be divided into five parts, viz. *standing*, *nocking*, *drawing*, *holding*, and *loosing*; and which are generally known by the name of *Ascham's five points of archery*.

**OF STANDING.** By standing is meant the attitude an archer ought to put himself into when about to draw the bow.

In the first place, the archer should stand with his left side towards the mark; his feet flat and firm upon the ground, the heels being about six inches apart, and his left foot advanced a little before his right, with the weight of his body resting equally on both legs, and not more on one leg than another: his knees should be *straight*, not bent, his hams being extended but possessing an easy firmness: his body should be upright, with his neck a little bent downwards. The left hand, which holds the bow, must be held out quite straight, the surest way to do which is to turn the wrist in as much as possible; by this means, the bow being grasped firmly, but not too tightly. As the string, when loosed from the right hand, strikes against the left arm, an implement is made use of called a bracer.

In drawing the bow, the right arm is drawn towards the ear; this, however, belongs more properly to *Drawing*.

**OF NOCKING.** By nocking is meant merely the fitting or placing the arrow on the string of the bow. The centre of the string opposite the top of the handle of the bow is whipped with stout sewing silk, to prevent it from being fretted and worn by the nock of the arrow. It is on this part that the nock of the arrow is placed previous to its being drawn, so that no difficulty can possibly arise.

The following directions for nocking, taken from Waring's treatise on archery, will assist the learner:—Hold the bow by the handle, in a horizontal position, with

the string upwards. Draw the arrow from the pouch, holding it by the middle. Carry the arrow under the string and to the left of the bow, holding it still by the middle, till the pile reaches the right hand, the fore finger of which is thrown over it, whilst the left hand is drawn back to the nock: look for the *cock-feather*, which having found, the arrow is slid down the bow and fitted upwards to that part of the string which is whipped with silk, taking care that the *cock-feather* stands *outwards from the bow*. The finger of the left hand is then removed and grasps the bow. In pulling up the string the thumb is not used: the two, or, by some, three first fingers, being all that are required, the arrow lying between the first and second. The string should be held between the tip of the fingers and the first joint.

OF DRAWING. Ascham observes that "drawing well is the best part of shooting, and it is better to draw to the ear than to the breast."

In drawing, Mr. Waring observes that, "as the left hand raises the bow, the right should begin to draw, so that when it is held up to its intended elevation, it should be above half drawn. It does not do to elevate the bow quite undrawn, for the right hand in reaching to the string, displaces the position of the body." It is the method of our best archers, as they raise the bow, to draw it three parts of the way, then pause to take aim, then draw it quite up to the head, and instantly loose; for it ought not to be kept on the full stretch more than a second or two for fear of breaking.

The archer should remember, that whether he be shooting at a short or a long distance, he ought always to draw the arrow to the head.

OF HOLDING. By holding is meant the holding the string when the arrow is drawn to the head. Ascham observes, that holding must not be long, for it puts a bow in danger of breaking, and also spoils the shoot: it must occupy so little time that it may be perceived better in the mind, when it is done, than seen with the eye when doing.

With regard to holding the bow itself, the perpendicular position is not only the most convenient, but is also the best for taking aim.

OF LOOSING. Loosing signifies the letting loose of the string; and, according to Ascham, must be performed much in the same manner as holding: so quick and

hard that it be without any twitches; so soft and gentle that the shaft fly not as if it was sent from a bow case. The mean betwixt both, which is perfect loosing, is not so hard to be followed in shooting, as it is to be described in teaching. For clean loosing you must be careful of not hitting any thing about you; and remember to hold your hand always the same height on your bow, that you may keep the length truly.

ROVING. By roving is meant the shooting at casual and unmeasured marks, such as trees, hillocks, stones, or any other object that may happen to appear. In this kind of shooting, a heavier arrow, called a *flight-arrow*, is used. Roving is sometimes practised at the butts instead of casual marks, the distances being changed every shot.

BUTT SHOOTING. Butts are made of sods laid one upon another, being in width about eight feet, and the height seven feet, growing narrower towards the top: the base is between three and four feet, and the top about one foot six inches thick. Butts are placed at various distances. Those erected by the Toxophilite Society are in sets; each set consisting of four, and each butt being thirty yards distant from the other; forming a chain of thirty, sixty, ninety, and one hundred and twenty yards, and disposed that they do not stand in the way of the archer when shooting at any of the lengths. Upon these butts (breast high, or about three feet and a half from the ground,) is placed the mark, which is a round piece of paper, fastened with a peg through the centre, being of smaller dimensions as the distances are shorter;—thus, for one hundred and twenty yards, the mark is sixteen inches in diameter; for ninety yards, twelve inches diameter; for sixty yards, six inches; and for thirty yards, four inches.

No shot is counted that does not hit the pasteboard, and he who hits it oftenest during the day is the winner: where two, however, reckon the same number, then he who is nearest the peg has the game: if it be doubtful which is the nearer, they shoot again, and he who hits nearest the mark, in any part of the butt, or if both miss the butt, he who shoots nearest to it is the winner. The same rule holds good in target shooting.

TARGET SHOOTING. Target shooting is generally one hundred yards, and fifty yards. Targets are made of oiled cloth, on which are described five circles, the

innermost being gold; the next red; then inner white; next black; then outer white; and lastly, green. This target, which is four feet in diameter, is sewed upon a bass, made of compressed straw, worked in the manner of a bee hive, which is supported by a stand or frame. Ladies' targets are considerably smaller.

For reckoning the numbers, two ways are used; one, by the mere number of hits, without regard to the circles; the other, by the hits as they approach the centre, counting nine for a hit in the gold; seven for a hit in the red; and so on—counting two less for every circle as it gets farther from the centre.

HOYLE SHOOTING is the same as roving; hoyle being a north country word for a hillock, tuft of thistles, mole hill, or any other little eminence.

FLIGHT SHOOTING is so called, the arrow being shot without any mark, the object being merely who can shoot his arrow the farthest.

CLOUT SHOOTING. The clout is a small white target, generally about twelve inches in diameter. It is fastened into a short upright stick, which is driven into the ground, somewhat obliquely, till the lower end of the clout touches, or nearly touches, the ground. It is but very seldom used at present.

ARM. Of a horse, so called, is properly the fore thigh, from the elbow immediately under the chest, to the knee.

ARROW. According to Ascham, an arrow or shaft is composed of three principal parts, viz. the *stele*, the *feather*, and the *head*. By the stele is meant the whole length of wood of which the arrow is made.

In modern archery five kinds of wood are commonly used in making the steles of arrows; these five are deal, asp, and arbele; which are light woods; and lime, and Jamaica lance-wood, which are heavy: to these may be added a kind of light wood, brought from Flanders, and which Mr. Roberts supposes to be poplar.

Ascham observes, that "a stele must be well seasoned, to prevent warping, and it must be made the same way the grain lies and as it grows, or else it will never fly clean.

The best length of arrow for a bow five feet eight inches long, is supposed to be twenty-seven inches, including the pile: of this length arrows are now made in England. For roving and shooting great lengths, it is customary to use an arrow twenty-eight, twenty-nine, or even thirty

inches, as the range and power of the drawing arm is considerably increased when the bow is much elevated.

The weight of arrows is generally proportioned to the distance to be shot; and in weighing them, silver money, at the mint standard weight, instead of pounds, ounces, &c. Arrows weigh from 3s. to 20s. though seldom shot with above six or seven.

Waring says, that arrows of any shape, if straight, will fly well at almost every distance within the power of the bow.—Many archers, however, differ in this respect, every shape having its advocates, and difference of opinion prevails even in the shape of the head, some maintaining that a blunt pile is best, and others the contrary. A blunt pile has this advantage, that when shot into the target frame it is more easily extracted.

By *breasted* or *high-chested* is meant a stele that is thickest in the middle and tapered off towards each end; which form is, by many, esteemed the best for any kind of shooting except very short lengths, or in a rough wind, as it floats longer in the air than one tapered or made heavy towards the pile. Ascham, speaking of piecing shafts, justly observes, that it is "more pleasant to the eye than profitable for use; as most arrows by piecing become somewhat sluggish, and lose a part of their former spirit: lime pieced with any hard wood, such as lance wood, makes a very good *roving* arrow.

The *nock* (which is that part of the arrow that rests against the string) is usually made of horn, or horn and wood, inserted into the end of the shaft, having a hollow to admit the string.

For the *feathers* of an arrow there is no other material besides a feather that will do for the purpose; as a feather is the only thing that will give place to the bow as it passes over it, and then rise up again to its original form. Ascham recommends the old goose feather for a wind or a dead shaft; a young goose feather for a swift shaft, and clipt somewhat high, as being weak, it will settle to a proper height.

Of late years, however, turkey feathers have come into use, as they are much stronger in their texture than goose feathers, and resist the wet better; they are also more beautiful in their colour and take a dye better.

The feathers of flight arrows are very short and low, being seldom longer than three inches, or higher than half an inch at the nock end.

The *head* of an arrow is the point, which, when not used for war, is termed a pile: this is usually made of iron, though the Flemish fletchers make some of horn, which answer very well. "Concerning heads for pucking, which is our purpose, there are various kinds, some being blunt, some sharp, and some both blunt and sharp; a blunt head in a calm or down a wind is very good—otherwise, none worse. Sharp heads at the end without any shoulders (I call that the shoulder in a head which a man's finger may feel before it comes to the point) will go quickly through." Mr. Roberts, in his English Bowman, observes, that "Ascham's observations that sharp heads pierce the wind better than blunt ones, deserves some consideration, and may require further experiment."

**ARROW, *barbed*.** A war-arrow having the head armed with barbs or wings (by the poets called beard.)

**ARROW, *bearing*.** An arrow which possesses a steady flight.

**ARROW, *bob-tailed*.** An arrow increasing in bulk, in a regular proportion, from the nock to the pile.

**ARROW, *breasted*.** An arrow which is largest in the middle; also termed *high chested*.

**ARROW, *broad*.** A war arrow with a flat barb, sometimes called a swallow-tailed arrow.

**ARROW, *bullet*.** An arrow made for throwing a bullet.

**ARROW, *fishing*.** An arrow made for striking fish.

**ARROW, *butt*.** An arrow used in shoot-at short butts.

**ARROW, *fluted*.** An arrow which is indented in lines to prevent its casting.

**ARROW, *rush-grown*.** An arrow formed like a rush.

**ARROW, *sheaf*.** The common war arrow, so called, because they were carried in certain quantities called sheafs.

**ARROW, *shot*.** An arrow used for casting small shot.

**ARROW, *taper-shaped*.** A rush-grown or *bob-tailed* arrow.

**ARSENIC.** This, though a violent poison to the human subject, may and often is given to the horse with perfect safety; it has been considered as a tonic. It is prudent to begin by giving the horse a small dose, as from two to eight grains. This may be gradually increased, and continued as long as there is occasion. It has been said to have cured the glanders, but on reviewing the experiments that

have been made with arsenic on glandered horses, it does not appear that it has ever done any good.

**ARTERIES** are the pulsating canals, conveying the blood from the heart to the extremities.

**ARTERIOTOMY** is the opening of an artery, for the purpose of taking away blood. This operation is performed only on the temporal artery of the horse; the pulsation of which, may be felt in the temple, about two inches from the outer corner of the eye; where it may be safely opened with a lancet. There is generally more difficulty in stopping the bleeding when you have taken away enough, than in opening the artery. The best method of stopping the bleeding is to make a complete division of the artery, the ends of it will then shrink within the cellular membrane, and the bleeding will very soon cease.

**ASCARIDES.** Small worms in the intestines of horses and other animals; they are chiefly confined to the rectum. See worms in horses.

**ASHTON, b.** bred by the Duke of Hamilton, in 1806; was got by Walnut, out of Miss Haworth, by Spadille, grandam by Clayhall Marske; great grandam, by Herod; great-great grandam by Goldfinder—Compton Barb—Vanessa by Regulus—Fox—Bloody Shouldered Arabian—Basset Arabian—Arabian mare. In 1809, Ashton won 240 guineas at York, the great St. Ledger and the Doncaster stakes at Doncaster: in 1811, one of the subscription purses at York. Ashton was the first produce of his dam, full 15 hands 2 inches high; and covered at Woodford, at ten guineas.

**ASSASSIN, b.** bred by Lord Egremont, 1779; got by Sweetbriar, out of Angelica, by Snap; grandam by Regulus;—Bartlett's Childers—Honeywood's Arabian—dam of the two True Blues. In 1781, Assassin beat the Duke of Grafton's Puzzle, a match at Newmarket, 100 guineas; in 1782, he won 140, 300, 300, 500, 100 guineas at Newmarket; and the Derby stakes at Epsom; in 1783 100, 150, 300, 500, and 50 guineas at Newmarket.

**ASTRINGENTS** are medicines that check morbid evacuations, as in diarrhœa, or purging, &c.; they are also used externally, as in grease; for internal use, extract of catechu, gum kino, and dragon's blood, are often employed; externally the preparations of lead and zinc, alum, &c. are generally preferred as astringents.

**ATTACHMENTS (Court of)** a ceremony or court peculiar to the laws of a

forest, and necessary to be known only to those who reside therein. The officers of this court do no more than receive the attachments of the foresters, and enrol them in the verderers' rolls, that they may be ready for the court of swainmote, when held. This court of attachments having no power to determine upon cases of offence or trespass, beyond the value of fourpence; all above that sum must appear in the verderers' rolls, and be sent by them to the court of swainmote, there to be tried according to the forest laws, which are replete with peculiar privileges, immunities, and what are termed royalties, appertaining to the crown itself.

**ATTAINT.** An old term given by farriers to wounds caused by the horse overreaching; that is, a wound in the heel or back part of the fore-leg, inflicted by the toe of the hind foot.

**ATTIRE** of a deer. Of a stag, if perfect, is called the burr; the pearls (the little knots on it) the beam; the gutters, the antler; the sur-antler, royal, sur-royal; and all at top the croches.

**ATTIRE** of a buck; the burr, the beam; the brow-antler, the sur-antler; the advancer, palm, and spellers.

If croches grow in the form of a man's hand, it is then called a palmed head. Heads bearing not above three or four, the croches being placed aloft, all of one height, are called crowned heads; heads having double croches, are called forked heads; because the croches are planted on the top of the beam like forks.

If you are asked what a stag bears, you are only to reckon the croches he bears, and never to express an odd number; as, if he hath four croches on his near horn, and five on his far; you must say he bears ten, and a false right on his near horn (for all that the beam bears are called rights); but if four on the near horn, you may say he bears twelve, a double false right on the near horn; for you must not only make the number even, but also the horns even with that distinction.

**AUGUST.** This month may properly be termed the first of the sportsman's year, as red grouse shooting, the earliest of our field sports, properly so called, commences on the twelfth, and black game shooting on the twentieth. Angling, it is true, may be said to begin in March or even February; but then it is a diversion, *sui generis*, which bears little or no relation to any other branch of field sports; and is indeed seldom characterised as such.

Angle for chub with gentles or greaves;

also with bumble-bees, moths, and blue flies.

Golden plovers frequent the lofty hills of Scotland and the North of England.

Fish for roach and rudd with gentles, little white snails, or flies under water.

For dace, bate with gentles, greaves, or small flies.

Otter hunting still continues, and may be said to continue during all the warm months.

Angle for trout and grayling with fern flies, harry long legs, orange flies, spinners, batter stone flies, ant flies, and lesser whirling dums; for bottom angling, or for roving for trout, only use minnows or worms.

Fish for barbel with red worms, greaves, or gentles.

Knots and godwits now begin to be taken with nets in the fenny counties.

Angle for bleak with gentles, house flies, or the artificial ant fly.

The stone curlew, or Norfolk plover, in dry stony upland meadows and downs.

Rove for perch with brandling or minnows.

Troll for jack and pike.

Fish for carp and bream, with worms, paste and gentles.

Salmon generally spawn in this and the foregoing month, and immediately begin to descend towards the sea. In the Thames, however, they begin to ascend in this month.

For pope or gudgeons use blood worms or gentles.

Seek for curlew on upland boggy and heathy moors.

Tench come in season again; bait with gentles and sweet paste.

Red deer go to rut.

With this month flapper (young ducks) shooting ends, they being now able to fly, and of course no longer *flappers*.

**AVIARY.** A place set apart to keep birds in; being generally so large as to allow them a degree of freedom nearly approaching to their natural state.

**AURELIUS**, chesnut, was bred by Lord Grosvenor, 1785, a son of Eclipse, dam by Blank; grandam by Snip; great grandam by the Godolphin Arabian; great-great-grandam by Frampton's White Neck. Aurelius was the only son of Eclipse, out of a blank mare; he was a horse of great power, and very like his sire in shape, marks, &c.; full 15½ hands high, and was considered the best three year old in the kingdom. At the first Spring meeting, 1788, the first time of his starting, he won

the third class of the Prince's stakes of 100 guineas each; beating Grey Diomed, Amadis, Minos, Eagle, &c.; at the same meeting he won the main of the Prince's stakes of 200 guineas each, beating Grey Diomed and Feenon, allowing them 3lb. Sir Thomas and Amadis paid forfeit; after

which he ran for the Derby Stakes, when amiss, and was second to Sir Thomas, beating Altamont, Feenon, Grey Diomed, Young Highflyer, Star, Ponto, Goliah, Conflans, and Jupiter.—He was sire of Marius, Rolliker, &c. and covered in the neighbourhood of Bristol, at five guineas.

## B

**BABBLER** is a hound, upon whose tongue no reliance can be placed, either in drag, upon trail, or the recovery of a fault; so strictly true is the well known adage, that “a liar is not to be believed although he speaks the truth.” A halter is a certain remedy for the babbling hound, and the only known cure.

**BACK.** See **ABACK**.

**BACK OF A HORSE.** The part upon which the saddle is placed. Upon the shape of the back a great deal of the beauty and utility of the horse depends. If he is long in the back, narrow across the loins, and light in the carcase, with flat ribs, he can never be considered either a strong horse, or a handsome one, however good he may be in other points.

**BACK-BEAR, BACK-BEREND, BACK-BEROND,** in the forest laws signified *bearing upon the back*; and the circumstance of a man being found *back-berend* was one of the four cases wherein a forester might arrest an offender against *vert and venison*, when he was found carrying a deer upon his back. The other three were **DOG-DRAW, STABLE-STAND, and BLOODY-HAND.**

**BACK, GALLED.** Horses are sometimes hurt on the back, by the saddle or harness; this can only occur from the inattention of those who have the management of them. Great care is necessary in examining the saddle, or harness frequently; to keep them in proper order; and if any injury or lump is found on the horse's back, the pads of the saddles or harness, should be examined; when the cause of the injury, will, in general, be very soon found. It can be of no service to apply any thing to a galled back, while the pressure which originally produced it, is continued: and it is from such culpable and cruel neglect, that very troublesome abscesses and fistulas are produced. When the harness has been made to fit the horse properly, very little more is required to get the back well again. If it has produced a sore, dress it with the following ointment:—

Saturnine ointment, two ounces.

Alum, in fine powder, half an ounce.

Mix.

When a swelling only is observed upon the horse's back or shoulder, you may bathe it frequently with the following lotion:—

Vinegar, four ounces.

Goulard's extract of lead, an ounce.

Water, one pint. Mix.

Cloths dipped in this, should be laid on the part, and changed whenever they become dry.

**BACKING.** In horse-breaking, signifies the first time that a colt is mounted, after having previously undergone all the ceremonies of *handling, quieting, stabling*, together with the discipline of the ring, &c. &c. For the proper method of *backing* a colt see **BREAKING THE HORSE.**

**BACK-RAKING** is an operation which consists in introducing the hand into the horse's fundament, in order to draw off any hard dung that may be in the gut. It will be rendered much more easy, by giving the horse a clyster previously to performing the operation.

**BACK SINEWS.** These are the tendons on the back part of the fore and hind leg of the horse, extending from the knee or hock to the fetlock joint. They are very liable to injury from strains, &c. they are flexor tendons, and consist principally of two, one inserted into the bottom of the coffin-bone, and the other into the pastern; this last serves as a sheath to the former. See **STRAINS OF BACK SINEWS.**

**BACK WORM, or FILANDER.** A disease incident to hawks. These worms are about half-a-yard long, are very troublesome to the bird, and will ultimately kill him. They lie wrapped up in a thin skin about the reins, and proceed from gross and viscous humours in the bowels, occasioned by indigestion and want of natural heat. This distemper is easily discerned by the following symptoms; namely, by the hawk's fetid breath, casting her gorge, croaking in the night, trembling, ruffling,

and writhing her tail; by the muting, which is small and unclean; and also by keeping at a stay in a low state of health. The back worm is seldom quite extirpated; but cloves of garlick, steeped in worm-wood, and given her once a fortnight, prior to her being put into the mew, will check or neutralize the disease; and without this precaution the bird will be suddenly spoiled. There is another sort of

filander, which lies in the gut or pannel, being long, small, white and red worms: for cure, take aloes hepatic, filings of iron, nutmeg, and as much honey as will serve to make them into a pill, which should be given to her in the morning as soon as she has cast; and after she has muted completely away, good warm meat should be given her.

**BADGER.** This animal cannot be said to afford diversion to the superior classes of the present day; yet a particular notice of it is indispensably necessary. The badger is very well known in this country, and is occasionally found in all the temperate parts of Europe, Asia, and America. Its general length is something more than two feet, and that of the tail six inches. Its body and legs are thick. The eyes and ears are small, and the claws of the fore legs long and straight. It is of an uniform grey colour above, and on the under parts entirely black, a singular circumstance, animals being generally darkest coloured above. The face is white; and along each side of the head runs a black pyramidical stripe, which includes the eyes and ears. The hair is coarse, and the teeth and claws peculiarly strong. The badger inhabits woody places, the clefts of rocks, or takes up his abode in burrows which he forms in the ground. He is a very cleanly animal, and keeps his subterraneous mansion exceedingly neat. He continues in his habitation during the day, and does not make his appearance abroad till the evening. At times, from indulging in indolence and sleep, he becomes excessively fat. During the severe weather in winter, he remains in a torpid state in his den, sleeping on a commodious bed formed of dry grass. Under the tail is a receptacle, in which is secreted a white fetid substance, that constantly exudes through the orifice, and gives him a most unpleasant smell. They live in pairs, and produce in the spring four or five young. If caught before they are grown up, they may be tamed. The flesh, when the animals are well fed, makes excellent hams and bacon, their mode of feeding being somewhat similar to that of the wild hog.

Badger-hunting is a sport occasionally enjoyed by the rustics and lower orders. As the badger is generally either under ground, or in some place of security, during the day, the diversion is followed by moonlight. At a late hour in the evening, when the animal has left his strong hold, in order to supply the cravings of hunger, some of the party, according to previous agreement, proceed to place a sack lengthways in the burrow, and so contrived that the mouth of it directly corresponds with the mouth of the burrow, and it is secured in that position by means of a willow hoop, which, from its pliability, readily submits to the form required. This part of the business being completed, and the party who fixed the sack withdrawn to a convenient distance, the signal whistle is given, when their distant companions lay on the dogs, (terriers generally, though there

are few dogs that will not pursue the badger,) encouraging them through the neighbouring woods, coppices, and hedge-rows; which the badgers abroad no sooner find, than they make to their earths for shelter. They enter the sack, and are immediately secured by those stationed near the spot for the purpose.

Badgers are sometimes dug out of their subterranean retreats; which, however, can seldom be effected without much labour and difficulty, as the animal's fortification evinces much instinctive ingenuity, and will be frequently found to terminate in a variety of ramifications amongst the roots of trees. At all events, digging of badgers, without very good dogs, is a work of time; for should the terriers not keep constantly at him, from his facility of penetrating and throwing back the earth, he will, in a loose soil, bury himself faster than the workmen can sink pits, by which he may be got into an angle.

Badger-hunting was formerly considered an amusement; and, amongst other directions to promote the sport, one was, to entice them from their holes by drawing a piece of pork (of which they were supposed to be remarkably fond) over the entrance, which would induce them immediately to make their appearance. Another story told of them was, that they lived a number of years, and when they lost their sight, through age, they kept in their burrows, and were fed by the younger of their tribe. A third was, that their legs were longer on the right than on the left side, and therefore, when they were pursued, they took care, if possible, to run along the side of a hill, bank, furrow, or cart-rut.

Few animals have suffered more from vulgar prejudice than the badger: inoffensive in his nature, he appears to have acquired the character of ferocity merely because he possesses uncommon strength, and is furnished with strong teeth, as if formed to live by rapine. He has been charged with destroying rabbits and game; but the circumstance seems to rest on no well-founded authority. Nature has denied the animal the speed requisite to escape from its enemies, but has, at the same time, provided it with the most formidable weapons of defence: few animals defend themselves better, or fight harder; and hence, perhaps, we may perceive the origin of badger-baiting.

According to some old sporting-books, the badger was distinguished by several appellations; viz. a *graybrock*, *boreson*, or *bausow*. The male was called a *badger*, or *bore-pig*; and the female a *sow*.

Naturalists once distinguished this animal by the name of the *swine-badger* and the *dog-badger*, from the supposed resemblance of their heads to those animals, and thus divided them into two sorts; but the most accurate observers have been able to observe only one kind, that whose head and nose resemble those of the dog; and Buffon remarks, that the badger admits of no varieties, nor does it even approach to any other species.

Badgers have, at former periods, been used to enter young fox-hounds; and for this purpose their long teeth were first broken; but it was a bad practice, and has been utterly abandoned for some time.

As the badger is known to be a very cleanly animal, it has been asserted that the fox takes advantage of this niceness, and uses an obvious method to make the badger's home unpleasant, of which he by this means possesses himself; but this is founded on no better authority than mere conjecture.

The fat of the badger in some parts is in great request for ointments and salves. The skin, dressed with the hair on, is used for pistol furniture. The Highlanders make their pendent pouches of it. The hair is also made into brushes, to soften and harmonize the shades in painting, and which are called sweetening tools.

**BADGER-BAITING.** In baiting the badger, the animal is put into a long narrow box, with an opening at one end and at the top. One person stands with a watch, in order to calculate the time: the keeper of the badger having placed the animal in the box. Whoever wishes to *draw him* sends in his dog, which immediately seizes his opponent, who likewise is not slow in returning the compliment so that both get fast hold of each other. The dog is then drawn out by the tail, and the badger with him; they are then separated; the badger is turned into his box, and the same dog attacks him again, showing his *bottom* by the number of times he lays hold of the badger in a minute, so as to allow his master to drag them both out together.

**BADGER-HUNTING.** See **BADGER.**  
**BAIT.** Independent of those fish which are used as live and dead bait, and which I shall notice in **TROLLING**, **LIVE-BAIT**, **FISHING**, &c. a number of objects, chiefly of the insect and reptile tribes, are used in bottom angling. Flies are not, however, classed under the head of **BAIT**. (See **FLIES** and **FLY-FISHING**.) The most common bait, especially near London and other large towns, is

**THE GENTLES.** Gentles or maggots may be bred from any animal substance, either fish, flesh, or fowl, (those from fish are the least worthy,) by exposing it to flies to blow on during the spring and summer. I have found flies in winter among ivy on walls that are fronting the south, and on a warm day have procured them, by which means I have had flesh blown by flies, and bred gentles, in every month during winter: after they are of a full size, put them in a vessel with some house sand: some use bran; but, from its heating quality, the gentles sooner turn, as anglers term it; that is, become a chrysalis, in which state they are of little or no use. In London it is not worth the trou-

ble of breeding gentles; for as many as will serve a day's fishing may be purchased at any of the tackle shops for a few pence. The least troublesome method I am acquainted with, to keep gentles during the winter, is to get some full-grown ones as late in the season as possible, and put them with fresh mould and half-dried cow-dung into a vessel two or three feet in depth, which vessel must be kept in a cool cellar or outhouse, occasionally sprinkling a little water over them; by adopting this plan, I am seldom without gentles in February, March, and April, in which months they are a valuable bait. When you use any at this season of the year, (during spring,) take only as many as you are likely to want, and keep them cool and close, or they will soon turn to a chrysalis if exposed to the air, and therefore close up immediately the place you take them from.

In the summer season, when on a fishing excursion from home, I take a quantity of gentles rather green with me, and daily give them a small piece of fresh flesh or liver, or a small fish; the small gentles then increase in size, and keep up my stock.

When you go out for a day's angling with gentles, put them in damp sand or earth; for if put in a box with bran, they may turn. Note—carp, tench, barbel, and chub, prefer gentles that are somewhat green.

Anglers who live in the country may, if they choose, breed and preserve gentles all the year, in the following manner: get the whole or part of a bullock's liver in October, or the heads of sheep with part of the wool on. Cut gashes in them, and let them be well blown by the flies: when the fly-blows are become full-grown gentles, put them and the remainder of the liver or heads into a tight cask or tub, having first put into the tub or cask about a peck of fresh mould from the fields, to

which add half the quantity of half-dried cow-dung, and then put the same quantity of mould and dung over them; keep them in a cold place; and when the mould, &c. at the top becomes dry, sprinkle a little water over it. Using liver or heads I think less disagreeable than having a dead animal blown by flies; but those who prefer a rabbit, or hare, or cat, or dog, have only to follow the directions given above, and they will have gentles at all times. Those who object to having gentles in their house, may preserve them in the garden, by putting the liver or other substance with gentles, mould, or dung, in a hole about three feet deep; but note—this hole must be plastered round and at the bottom with strong clay, or the gentles will penetrate into the earth to a great distance. I find those bred from rabbits or hares, or heads, less liable to burrow in the earth, because the skin and wool keep longer moist, and also afford them food. When you open the store, do it carefully; for when the cool spring air reaches the gentles, they quickly become a chrysalis. Horse-dung is too hot for gentles; but cow-dung nourishes them, as will hog's-dung also, but in a less degree.

The best way to keep gentles in the summer, is to put them in a salmon-kit (which may be bought of the people who sell pickled salmon) with some house sand, and sprinkle daily a handful of dampish sand over them, or a very little water, and they will keep from changing to a chrysalis much longer than if kept in a box or bag; for the kit, being very broad at the bottom, enables the gentles to move about and keep themselves cool; but when they are laid on each other in heaps in a box or bag, they soon become heated, and, in consequence, soon change to the chrysalis state.

WORMS are a useful and a general bait for fish, of which there are many different species. I shall describe those which are most fit for the angler's purpose, which are six different kinds; namely, the lob, the marsh, the brandling, the red, the blood, and the tag-tail worm. There are small worms found about the roots of dock-weeds, cabbages, turnips, potatoes, &c.; but they are much inferior to either blood or red worms.

*Lob Worms, large and small, by some called the Dew or Garden Worm; by others, the Twatchel, or Squirrel Tail.* These worms, which are the largest used in angling, are generally found in gardens, and may be gathered in great numbers in a

damp evening during the spring and summer, when they come out of the ground, or by digging for them where much manure has been laid; they may also be got by laying straw on the ground, and pouring water over it; they then soon come near the surface: and they may also be forced out of the ground by pouring a strong mixture of salt water on it, or by forcing a dung-fork or spade in the ground, and shaking and loosening the earth therewith. The lob is a good bait for trout, barbel, eels, and perch, particularly for night lines, during the early part of the summer. Note—the largest lob worms are of a dirty yellow whitish colour; the smaller, a brownish red, with a flat tail, something like a squirrel; always prefer the large lob.

*Marsh Worms or Blue Heads* are very common, particularly in marsh lands, and may be found under every lump of cow-dung in the fields or commons, or dug out of garden fields or dunghills; in fact, wherever you find earth, you may find marsh worms, especially in the spring and in marsh earth mould: in colour they are a dark brown, with a blueish gloss of a fleshy substance, or fat, and, when well scoured, by which they loose their earth inside, and are filled with a white sort, they are an excellent bait for trout, perch, and most large fish. The poor people who supply the London tackle-shops with worms, get a great number of marsh worms on Kennington Common in the night, using a candle and lantern to see the worms; this method is practised in spring and summer, particularly after warm rain has fallen in the evenings.

*Brandlings* are found in great numbers in dunghills, particularly in those which have lain some time, and become very rotten: they are used for carp, perch, &c. This worm is striped with red and yellow across the whole body. Brandlings are more used by provincial than by the London anglers; they should be kept several days in moss, to scour out the bitter pungent mixture with which they abound.

*Red Worms.* Some red worms are found in old dunghills, and they also breed among the bark after it has been used by tanners, and thrown out in heaps; but the principal places where they are found, are the banks of the great common sewers near the metropolis; from which places the tackle-shops are chiefly supplied, as those banks close to the water breed lob, marsh, brandling, and red worms, in immense numbers. Several poor people get part

of their living by procuring these worms, which they sell to the London tackle-shops at per hundred. The red worm, when well scoured, is of a fine bright red colour, with a knot or belt in the middle; it is the best and most killing worm for carp, tench, barbel, chub, dace, perch, gudgeons, eels, flounders, bream, &c. Too much cannot be said in praise of well-scoured red worms: two on a hook are very enticing to perch, barbel, carp, chub, tench, &c.—indeed, hardly any fish will refuse them, especially during the spring, autumn, and winter; in summer you may use them in the evenings of wet days, because at such times worms move, and the fish then expect them on the banks, from which they frequently drop into the water.

*Blood Worms.* This worm, or maggot—for it seems to be covered with a case or chrysalis, and at last becomes a gnat-fly (the smallest used in angling)—is found at the bottom of shallow ponds in cowlayers or yards, and is bred from the excrements of the cows and other horned cattle. By gathering the earth, sand, and dung, from these ponds, innumerable blood worms may be found; some are also to be met with in the ditches or drains that run from houses, farm-yards, &c. but they are not so large as those found in the cowlayers. In the ditches, drains, and sewers, the curious may find so many blood-worms, that certain parts appear a mass of blood, over which innumerable gnats are playing; they are about an inch long, and not much thicker than a worsted needle, and of a blood-red colour, from which they take their name: they generally appear in April. This worm is very lively, and a most killing bait; for many fish, particularly gudgeons, carp, roach, dace, &c. Put two or three on the hook together. To preserve them alive, keep them in some earth mixed with a little damp cow, horse, or pig-dung; or they may be kept in the soil you find them in when taken from the ponds.

*Marl or Tag-Tail Worms.* This worm is so called from its having a yellow tail: they are found in marly lands and clayey banks; and it is a clean, light, red-coloured worm, with a deep head, very strong and lively on the hook, and requires but little scouring. Two of them put on a No. 6 hook is the most killing worm bait for trout in the morning early, and late in the evening, particularly during the month of April, and after rain, while the water is a little coloured: so are the smaller size, for dace, roach, perch, and gudgeons. Note—dur-

ing the spring months, this worm cannot be too much prized.

*CATERPILLARS.* Caterpillars, found on cabbages, lettuces, and indeed almost every kind of plant or bush, are excellent baits for most fish.

*SHRIMPS.* Live or dead shrimps are a good bait for perch, eels, ruffs or pope, and flounders. If dead, the shell or case must be taken off before you use them. When you use shrimps for a bait, enter the point of your hook in its side near the back, and bring it to the side of the head near the eye. During the summer months, the canal crossing the Isle of Dogs abounds with shrimps, which are easily taken with a minnow or fine landing-net. Note—when angling for perch, carp, pike, barbel, chub, roach, &c. during the months of June, July, August, and September, you must not expect them to feed in the middle of the day, say from eleven till four o'clock in the afternoon, unless the weather is very dark and gloomy. During drizzling rain or a light breeze of wind, therefore, fish early and late, or you lose your time and labour.

*TO CLEANSE AND KEEP WORMS.* The best method of cleansing or scouring worms from their filth, is by putting them into damp moss. Persons who live in the country have it in their power to get moss with little trouble, as it grows in most fields on commons and on banks. About February and March it is in the best state, at which time I generally procure as much as will last me for twelve months: in London it may be purchased at the herb-shops in Covent Garden Market, Fleet Market, and, I believe, all the vegetable markets.

Worms should lie in moss two or three days before they are used; they will then be much brighter, larger, and more lively than when first taken. If you find any of them bruised, mutilated, or sickly, throw them away; for if they die, their bodies soon become corrupt, spoil the moss, and will occasion the death of others; therefore make it a rule, when you leave off angling, or when you have returned from it, to look over your worms, cast away the diseased, and give the remainder some fresh damp moss, or a piece of damp old net, or coarse hempen cloth: and if you find, when out angling all day, that the worms you have with you seem sickly, gather a little grass and damp it, and put it among them, which will much refresh them. Some dip their bag of worms in the water; but it is a bad practice, for it frequently kills them all.

TO PRESERVE A STOCK OF WORMS ALL THE YEAR. Take about a pound of mutton suet chopped into small pieces, and put it into a saucepan containing about a quart of water; let it boil slowly until the suet is dissolved, and then into this liquor dip some pieces of coarse hempen sack or cloth, such as is called coarse wrappers at the linen drapers, or old coarse worn out traces, or old nets, or old nail bags, though the new cloth is best if very coarse, and before it is used it should be well washed, to free it from the oil or dressing which may adhere to it from the loom: when the cloths are well saturated with the fat liquor, and cold, mix some fresh mould with them, and put the whole into a deep earthen vessel, or small tub; into this pour a good stock of marsh or red worms, and over the top tie a cloth, to prevent them escaping, and in which there should be a few very small holes to admit air. If the vessel is placed in a cool dark cellar, the worms will feed and cleanse themselves, and keep lively and fit for use for many months. It is very advisable to keep the different species of worms in separate vessels, so that the angler can at any time select the sort and quantity necessary to be placed in moss preparatory to using them.

During the time your worms are in pans or tubs, it will be proper, when the earth they are among gets very dry at the top, to place those vessels for a few minutes in a gentle shower of rain, or to dip your hand in water and sprinkle some on it; but soft rain refreshes them amazingly, therefore is to be preferred.

Brandlings will live some months in pans or tubs half filled with dung from a pig sty, mixed with yellow gravel, changed once a month as follows:—turn the pan or tub upside downward; put in fresh dung and gravel; then put the worms in again; if any are dead cast them away.

The best time to collect a stock of worms is in March or April, for at that season they are very healthy, and may be kept more than twelve months, by following the directions here given.

I would advise the angler always to take a few red worms with him when he goes to fish, even if he intends to try for roach or any other fish; for, although paste is the proper bait for roach, yet sometimes a perch will make his appearance among the roach, which he may have collected about his baited hook, and his sport will instantly cease: in that case a worm bait is the best remedy; for, on ap-

plying it, the disturber is generally soon taken.

Lob, marsh, brandling, red and blood worms, may be purchased at most of the fishing tackle shops in London, at from three pence to sixpence per hundred.

WASP, GRUBS, MAGGOTS, CLAP BAITS, AND CASE WORMS, OR CAD BAIT. The young wasp or bee, when in the state of maggot, is an excellent dapping and tripping bait for trout: this maggot is much like the common gentle, but considerably larger; use a No. 8 hook, and put a good bunch of them on at a time, and let them swim down the current, touching the bottom. There are two kinds of maggots which were used by anglers formerly, but the experienced of the present day very properly reject them. These maggots, or, as some call them, bobs, and grubs, are found when turned up by the plough, particularly in the spring, and in a sandy soil; they are three times as big as a gentle, and have a red head: they are the breed of insects called cock-chaffers; they afford food for rooks, who will closely follow the plough in search of them, and during the season grow very fat upon them. The other is called the cow dung bob-grub, or clap-bait; they may be found early in the spring months, and parts of the summer, under half-dry cow dung, in meadows, grass commons, &c. This maggot is the produce of the blue or cow-beetle, which flies about in the summer evenings, and frequently smites the patient angler on the face in his return from his favourite amusement. Its colour is a dusky yellowish white, and some have a dark coloured head.

The only success I have met with in angling with those bobs or grubs (those grubs or maggots are used chiefly by country anglers, in still waters, especially for perch; they are found in a light mould, and under and about cabbages, potatoes, &c. they are very tough, and will live a long while among half-dried cow dung or light mould; they vary in colours, some are gray—which I have found the best—others green and brown,) has been while fishing for perch, and have sometimes taken perch in the months of July and August (especially in ponds and still waters,) when they refused a worm, but they have generally been small fish. There are also two or three other insects, known by the names of cad-bait, cadis, or case worms, or maggots, which may be kept and scoured in a box or bag in damp house sand; these, though an excellent bait for

most fish, are not worth the trouble of getting or preserving while gentles can be procured; when they are changed into a fly, some use them sunk a foot into the water, by putting a small shot on the line, and will sometimes take a fish in this manner.

First, the cad in a husk or case; secondly, a complete fly; thirdly, on the wing. This fly is the stone fly; by some called the cad fly. The green and gray drakes are similarly incased in pieces of rushes, dried stems of weeds, &c. until they become flies, (those look like maggots or grubs, of a yellowish colour, that are found in cases, or husks of wood and stones, and those incased in rushy or weedy husks are invariably green,) case worms, rough coats, &c. which were used formerly in angling for roach, dace, and chub; but in respect to their value as bait for fishing, compared with what the modern anglers use, they are not worth naming or describing, yet are extremely curious as a natural production. The cad may be found on the margin of small rivers, (the banks of the New River and the Lea abounds with them,) adhering to the bank sides, or a little below the surface, and sometimes on the top, during the spring months.—This insect is about three quarters of an inch long, inclosed in a rough husk or case, the size of a large tobacco pipe stem, and has the appearance of small pieces of decayed sticks, &c. As the weather becomes warm they break through the case, and are a complete fly.

**SALMON SPAWN.**—Salmon spawn is described by some writers as a superior bait for trout, chub, roach, &c. The way to preserve it is as follows:—lay it on a board or trencher, and dry it gradually, then put it in a woollen bag and hang it in a moderate warm dry place, near the fire, or beside the chimney; when it grows too dry, soak it a little in water before you use it; put a piece on your hook something larger than a pea. Note: Salmon spawn is in the best state about two months before the fish spawns.

Among the various methods of preserving salmon spawn, the following is the best:—take one pound of full grown salmon spawn; put it into water as hot as you can bear your hands in, and wash off all the skin, &c. from the spawn, then rinse it by pouring on cold water, taking care that no skin, blood, &c. is left with the spawn; then put it into a cloth or bag, and hang it up to drain for twenty-four hours; then put with it about two ounces

of rock or bay salt, to which add about a quarter of an ounce of salt petre, and hang it up again for twenty-four hours more; then spread it out on a dish to dry dry in the sun, or before the fire, until it becomes stiff; then put it into a jar or gallipot, and run melted suet over the top of it, which should be well covered, and fastened with bladder and leather, to keep the air out.

**WHEAT.** Wheat is a favourite bait with some anglers; those who choose to try it must prepare it in the following manner:—take some new wheat in the state it is used for making furmity; bruise it a little, and then add a little milk or water to it; let it then be put into the oven, or parboiled over a slow fire, and when cold it will be in a state of a substance between glue and jelly; the grain will be the size of a large gentle; put one on the hook, same as if baiting with a gentle, but I prefer paste, having never killed so many large roach with wheat:—with pearl barley parboiled I have also killed many roach and rudd in ponds and still water.

**GREAVES.** All the refuse of the fat used by tallow chandlers, and forms a good bait for barbel, eels, and even trout: to prepare greaves for use, you must break it in pieces, and soak it in cold water till perfectly soft; then select the whitest parts and keep them dry for use.

**CHICKEN'S GUTS,** or of any kind of poultry, form, when fresh, excellent bait for eels, and occasionally for jack and pike.

**PASTE.** Paste is a killing bait for almost every kind of fish that breed in rivers or any fresh waters, but it requires some little time and labour to make it, which must be done with clean hands; also care and skill in using it. Many strange and ridiculous receipts are to be met with for making paste, which tend much to confound and puzzle the inexperienced angler; such as part of the leg of a kitten, with bee's wax, suet, &c. beat in a mortar; or, cherries and cheese, sheep's blood and saffron; or, cheese, flour, dead men's fat, aniseed water and roasted bacon: many others, equally useless and absurd, I could mention; but I shall better serve the novice in angling by assuring him that nothing more is wanted in making paste to kill every kind of fish which will take paste, than flour, bread, water and honey, (with a little vermilion or red ochre to colour the paste, which may sometimes be useful,) and teaching him how to make and use the same.

**SWEET PASTE FOR CARP, TENCH, CHUB, AND ROACH.** Take the crumb of a penny roll, or a piece of loaf the same size, of the first day's baking, and dip it into honey; then work it in your hands, that the honey may be well incorporated with the bread, and until it is of a sufficient consistence to remain on the hook: this is the most killing bait for carp I ever met with, during the months of July and August, and the rest of the season. Tench are also very fond of it; likewise chub and roach. I have taken many heavy roach with this sweet paste when they refused every other bait. The quantity I have named is enough for a day's fishing, but it is proper to take some to throw in occasionally close to your float, while angling. When honey is not to be had, dissolve a quantity of loaf sugar in warm water, and dip the bread therein; this makes a good clean and sweet paste when well kneaded.

**PLAIN PASTE FOR ROACH, &c.** Take a piece of the crumb of a roll or loaf the day after it is baked, about the size of an apple, and dip it lightly in water; immediately squeeze it as dry as possible, and then place it in your left hand, and with your right thumb and fingers, work or knead it well until it becomes exceedingly smooth and stiff. To make this paste to the consistence I have named, it will require to be kneaded a quarter of an hour at least. This paste, when well made, is the best bait used for roach, as they will seldom refuse it at any time of the year. Carp, tench, chub, dace, bleak, barbel, and minnows, will also take it.—This paste is valuable from its being easily made while you are at the water side; indeed it is most proper to make it there, especially if you fish at any distance from home, as it may chance to get somewhat sour by carrying it a length of time; it is further valuable in striking fish when they bite; for, if made properly, it will adhere to the hook until you have struck; it then flies all to pieces, consequently your hook is not impeded in fixing in the fish, which is material, particularly in angling for roach, when so small a hook as No. 10, 11, or 12, is used. New bread paste is more glutinous and adheres too close, which makes it unfit for a small hook.—This new bread paste is made by taking a piece or crumb of new baked bread, and a small piece of stale, and kneading it well together in your hands a few minutes, (without water) till of a proper consistence: those who prefer ease to sport, make use of the last mentioned paste in-

stead of that made of the second day's bread. To colour paste, add a little vermilion, or red ochre; a very small quantity will make it a pale pink colour; a little more, a poppy; but the pale pink or salmon colour is best.

**CHEESE PASTE FOR CHUB, AND GREAVES PASTE FOR BARBEL.** Paste made with cheese and bread is a very killing bait, particularly for chub, if made in the following manner:—take some old Cheshire cheese—the damper, the more rotten, and ranker, the better—and well work it, and mix it with the crumb of new bread until it becomes of a proper consistence to bait the hook with; if the angler will go to the expense and trouble of making ground bait, of a pound of old maggoty Cheshire cheese, and a new quartern loaf, and fish in still chub holes, he will have sport enough. To make paste for barbel, dip the crumb of a new penny loaf into the liquor that greaves have been boiled in, and knead it till stiff and fit for use. This bait is a killing bait for barbel.

In making paste it is absolutely necessary that your hands should be very clean, and likewise the bread and water, otherwise the paste will be of a bad colour, and taste. In that case you must not expect success. A paste is made by mixing water in small quantities with flour, and several times squeezing it dry, forming in the first instance a piece of dough; this dough must be worked in the hands through twenty or more different waters, till it becomes of a consistence almost as sticky as birdlime: when made, carry it in a damp cloth, and you must invariably wet your fingers when baiting your hook: this paste is known to experienced anglers, and preferred, solely for its remaining fast to the hook, which it will do in any stream, however rapid. It is distinguished from other pastes by the name of patent paste; but my own experience has quite convinced me that the other kinds which I have described, are, in every respect superior, and which is also the opinion of the best anglers I am acquainted with. By using the different sorts of paste which I have enumerated, and for such fish as I shall direct, in their proper places, the angler may be assured of success, without the aid of oils, scents, or any other quackery.

**BAITING.** See bull baiting, &c.

**BAJAZET**, the property of Ld. March, was bred by Sir John Dutton, 1740.—Bajazet was a son of the Godolphin Arabian; dam by Whitefoot; grandam by

Leedes; great grandam a natural barb mare, the property of Queen Anne. In June, 1746, Bajazet gave Russett 6lbs. and beat him in a four mile match; in 1747, he won £50 at Beccles, Burford, and Epsom; in April, 1748, he beat Abraham, six miles, each carrying 12st. at Newmarket, 50gs.; in June, he beat Moorcock, by Blacklegs, at Winchester, 12st. each, £50; in June, 1750, he won £50 at Winchester, beating Drudge, by Crab, and Sir Charles Goring's Tom Thumb. Bajazet was a bay, with a little white on his off hind fetlock.

**BALD CHARLOTTE.** This mare, allowed to have been the best in the kingdom in her time, was bred by Captain Appleyard, in 1721. She was got by Old Royal, out of Bethell's Castaway mare; grandam, a gray mare by Brimmer; Brimmer was bred by the D'Arcy family, out of a royal mare by the Yellow Turk. In 1726, she beat twenty-three mares for the King's plate, at Black Hambleton; same year she won the October stakes at Newmarket, beating seven horses; on April 15th, 1727, she bore off the King's plate at the same place: three days after, carrying 18st. she beat Mr. A. Swinger's horse, 17st. a four mile match, for 200gs.: she also won the King's plate at Winchester, carrying 12st. In April, 1729, she gave Sir Robert Fagg's Fanny, 7lbs. and beat her, four miles, 300gs.

#### THE BALD GALLOWAY.

"In Whittlebury forest vast  
This goodly steed was rear'd."

He was the property of, and was bred by, Captain Rider. The Bald Galloway was got by the St. Victor barb out of a royal mare. We know but little concerning this horse; he was, however, sire of Old Cartouch, Buckhunter, Dart, Foxhunter, Gray Ovington, Lilliput, Judgment, Bauble, Daffodil, Roxana, Silverlocks, and several that won plates in the north, which brought him into repute as a stallion.

**BALLS.** This is the form in which medicine is most commonly given to horses. They are generally rolled up into a cylindrical form, about one inch in diameter, and two and a half in length. A little practice will enable a groom to give balls—though sometimes there is much difficulty in giving them without the instrument called a *balling iron*, and there are some horses that will not take a ball by any other means. When the balling iron is used, it should be covered carefully with listing or strips of flannel, to prevent

the mouth from being bruised by it. In giving a ball, the horse's tongue is drawn out on the right side, and held firmly with the left hand, while, with the right, the ball is quickly passed over the tongue, into the pharynx, or top of the gullet.—The moment the right hand is withdrawn from the mouth, the tongue is let loose, and the ball is generally swallowed. The balling iron is to be removed immediately after the ball has been passed into the throat. Balls should be made at the time they are wanted, as by keeping, they will become so hard as to be almost insoluble in the stomach, besides losing much of their strength, this particularly when the ingredients of which they are composed are of an evaporating nature, as camphor, ammonia, and the essential oils. Horses have been destroyed from the balls having been kept until they became very hard, they have then stuck in the throat and choked them. Balls cannot be conveniently given unless they are wrapped up in paper; for this purpose the thinnest and softest should always be chosen.

When more than one ball are made at a time, you must observe that there is great care bestowed in mixing the various ingredients, so that each ball may contain an equal proportion of the articles employed, before it is made into a mass; this is usually directed to be done by adding syrup, but molasses will be found to answer as well. Soap is often used for bringing balls to a proper consistency for forming a mass, particularly purging balls; and when it is not an incompatible ingredient, is one of the best articles that you can employ. When a horse has a violent cold, or the disease called the strangles, it is not proper to give him either balls or drenches, for in these cases there is so much inflammation and soreness of the throat, as to render swallowing not only painful and difficult, but even dangerous.

The *alterative laxative* ball is formed by taking,

Barbadoes aloes, 11 drachms.

Soap (Castile) 1 ounce.

Caraway seeds powdered 1 oz. & a half.

To this some add about half an ounce of powdered ginger; the whole, after being well mixed, is to be formed into a mass, by adding a little treacle; it is then to be divided into four balls, one of which is to be given occasionally. While the horse is taking these balls, he must have mashes, and the chill just taken off his water; he should have moderate exercise.

For a DIURETIC ALTERATIVE BALL, take

Yellow resin	4 ounces.
Spanish or Castile soap	3 ounces.
Venice turpentine	2 ounces.

Caraway seeds powdered, enough to form the mass. The mass is then to be divided into balls of a moderate size; one of them to be given every day, until a diuretic effect is produced.

For a DIAPHORETIC ALTERATIVE BALL,

Antimonial powder	2 drachms.
Camphor	1 dr. & a half.
Flour	3 drachms.

Treacle enough to form the ball, for one dose.

CATHARTIC OR PURGING BALL, take

Barbadoes aloes powdered	6 drs.
Soap	3 & a half.
Ginger powdered	1 dr.
Oil of anise-seeds	12 drops.

Mix the soap and oil of anise-seeds into a paste, by beating them together in a mortar, with a very little water; when this is done, add the powdered aloes and ginger, and beat the whole into a ball. When the socotrine aloes are used, about 6 drs. made into a ball with a little oil and water, or soap, may be given; these generally operate in about fourteen hours, and you should give him a bran mash, composed of hot water and bran well mixed.

ASTRINGENT BALLS, for diarrhoea, &c.

Powdered catechu	3 drachms.
Alum	3 drs.
Powdered opium	half a dr.
————— ginger	2 drs.

Treacle enough to form the whole into a ball. To this some add about 12 drops of the oil of cloves.

CORDIAL BALLS. Take

Ginger powdered	1 dr.
Allspice powdered	2 drs.
Caraway seeds powdered	3 drs.
Oil of cloves	12 drops

Mix the whole into a ball, with syrup or treacle.—Or,

Allspice powdered	3 drs.
Caraway seeds powdered	6 drs.

Mix as before for a ball.

CORDIAL DIURETIC BALL. Take

Hard soap	4 drachms.
Common turpentine	4 drs.
Ginger in powder	1 dr.
Opium	half a dr.

Mix the whole into a ball, with powdered caraway seeds, or powdered liquorice.

BALSAMS. Of these there are several kinds employed in veterinary medicine; they are of various degrees of thickness, but generally fluid. They resemble resins, and, like them, are soluble in spirits of

wine. The principal balsams used, are, the

**BALSAM OF TOLU.** This is a solid resinous substance, of a fragrant smell; it is sometimes employed in chronic cough, with a view to promote expectoration: it is given in doses of from two to three drachms.

**CANADA BALSAM** is a pure kind of turpentine; it is not often employed, being very expensive; in comparison with common and Venice turpentine—the latter of which is sufficiently pure, and equally efficacious.

**BALSAM OF COPAIBA.** This is a diuretic, in the dose of about one ounce; it has been also employed in chronic cough, in diseases of the lungs, and in flatulent cholera.

**BALSAM OF PERU** is a dark-coloured, fragrant-smelling fluid, with a strong burning or acrid taste; the dose is from two to three drachms; it is much more stimulating than any of the former; like the other balsams, it has been recommended in chronic cough, and in broken wind, in its incipient stages. It is also used as an external application to ulcers of an irritable nature.

**FRIAR'S BALSAM** has long been a popular remedy for wounds, ulcers, &c. It is called the Compound Tincture of Benzoin, in the London Dispensatory, and is thus directed to be made:

Take of Benzoin	3 oz.
Storax balsam strained	2 oz.
Balsam of Tolu	1 oz.
Extract of aloes	half an oz.
Rectified spirits of wine	2 pints.

Let them remain together for fourteen days, and strain the liquor through blotting paper.

**BALSAM OF GILEAD** is much the same in its medical properties as Canada Balsam—strongly diuretic; it differs from the rest, principally in being of a much higher price. There was formerly another balsam much esteemed by the farriers of the old school, (or rather of no school at all,) in obstinate or chronic coughs, called Balsam of Sulphur, which was made by boiling sulphur and olive oil together. It is now very seldom employed.

**BANDAGES**, are very generally and properly used for swellings of the legs of horses, for weakness of the fetlock joints, and for windgalls. Bandages should be moderately tight, so as to support the joints, without impeding the circulation; they should be applied in such a manner as to press equally on every part, without causing any swelling either above or below

FISH. *Plate I.*

BARBEL, *p. 49.*

BLAB, *p. 50.*

CREAM, *p. 51.*

CARP, *p. 105.*

the bandage; for if they do this, they are productive of much more harm than good. They should be made of strips of flannel, which is preferable to linen, on account of its elasticity being greater, about three inches wide, the length, must of course depend upon the part to which they are intended to be applied; for the legs they ought not to be shorter than two yards each. Practice is the only thing that will enable a man to put on a bandage properly, simple as it may appear, in order that it may press equally, and not be disturbed by the movements of the horse. The best plan is to begin by giving the first turn of the bandage downwards, immediately under the fetlock joint; from thence bring it upwards over the front of the joint, in an oblique manner, it is then to be brought down again so as to form a figure of eight about the joint, then continue it up the leg. Tear the extremity of the bandage down the middle, which will enable you to tie it round the horse's leg when you have finished rolling it.

**BARB HOOK.** A kind of hook formerly used in trolling.

**BARB.** The beard of a hook.

**BARB.** The barbary Horse. See **HORSE.**

**BARBEL.** The barbel only breed and thrive in rivers. In the Thames and part of the river Lea, there are many very fine and large: they are a handsome fish, but their flesh is coarse, and therefore considered but of little value for the table; yet, I have been told they eat very well when baked, with veal stuffing in their belly, as do the smaller sized split and fried. The barbel is prized for being a game fish, affording excellent sport to the angler, mixed with some labour and anxiety. When of large size, they are exceedingly crafty, sulky and strong, struggling a long time after they are hooked, often lying motionless at the bottom many minutes, then running under banks, or into large beds of weeds, in fact, trying every possible way to get off the hook, or break your line, which they certainly will effect if you are deficient in skill, or your tackle is in any way faulty.

The barbel bites very sharp and sudden; you must strike on the instant and smartly, immediately raise the top of your rod, let him run some considerable distance before you attempt to turn him, then endeavour to keep your fish away from the shelves and beds of weeds, take him from the current into deep and still water as soon as possible, and play him till he has quite

lost his strength before you attempt to land him.

Before you begin to angle for barbel, throw in plenty of ground bait, (you can hardly give them too much,) and continue to do so frequently while fishing for them: the best ground bait is made with soaked greaves and clay, mixed together in balls the size of an egg, also clay and gentles: indent a piece of clay, in which put some gentles, close it lightly, and the gentles will work out gradually when at the bottom of the river. Use this ground bait only in still holes. A quantity of worms, if they can be procured, chopped into small pieces, are likewise a good ground bait.

The barbel feed from May till October, all the day, but best in the morning and evening; indeed the chance of success increases with the coming night. They will even bite all night, and will feed very freely after rain, when the water is thickened a little.

**BARBS.** The disease so called in books of farriery, is an inflammation and enlargement of the terminations of the salivary ducts, which convey the saliva into the mouth, from the glands which secrete that fluid. They are two small substances sometimes called paps (as is the disease), and on drawing out the horse's tongue on one side, may be seen in the under jaw, one on each side the channel or groove in that part. The remedy proposed is cutting them off with a pair of scissors, and afterwards touching the parts with lunar caustic, or common salt. But this may be productive of serious consequences, by causing obstruction in the salivary ducts. Indeed such an operation is never necessary. When horses are cutting their teeth, they have generally these parts inflamed, sometimes indeed to such a considerable degree, as to render feeding extremely painful. In these cases the inflammation will soon subside, by bleeding, and syringing the parts, with a solution of alum, and feeding on bran mash.—Barbary horses are called barbs.

**BARK, PERUVIAN, or CINCHONA.** There are three sorts of bark kept in the shops, the pale, the red, and the yellow; they differ very little in their effects; for though in the human subject bark is a very useful tonic and febrifuge medicine, it has little or no effect on the horse. It has been said to have been useful in the disease called *diabetes*, which is an excessive discharge of urine. When given to horses, the dose is eight drachms to one or two ounces.

BARREL. See FOWLING-PIECE.

BARBS. The fleshy ridges at the upper part of a horse's mouth are so called; these are always more prominent in young horses than in old ones. They are sometimes so much enlarged towards the front teeth, as to project below the surface of them, becoming so painful as to prevent the horse from feeding properly: this is called the *lampas* (which see). There are the bars of the foot likewise.

BASILICUM. A well known digestive ointment, now called ointment of yellow rosin. It is composed of yellow rosin and bees' wax, of each a pound; olive oil, one pint. Melt the rosin and the wax together by a slow fire; then add the oil, and strain it, while it is hot, through a linen cloth.—By adding to four ounces of this ointment, one ounce of oil of turpentine, and one ounce of red precipitate, finely powdered, you have a digestive and stimulating ointment, which will be found very useful for dressing foul and indolent ulcers on the horse.

BATE. In falconry a hawk is said to bate or bait, when she flutters with her wings, either from perch, or fist, as if striving to get away.

BATTLE ROYAL was formerly (much more than at present) a favourite mode of fighting amongst COCKERS of the *Lower order*, who, upon the old maxim of "the more danger the more honour," became practical advocates for general destruction in the following way:—a battle royal may consist of any number of cocks, but is hardly known ever to exceed eight. The owner of each having made good his stake, or previously contributed his share of the prize or purse for which they fight, and all parties being ready, the cocks are most inhumanly pitted at the same moment, when a long and distressing scene ensues, to which there is no termination as long as a second cock is left alive, and the victory can only be obtained by the last survivor."

BAY. The colour of a horse. Bays have invariably black manes and tails, with either black or white legs; they are of different kinds, such as *light* or *yellow bays*, *brown bays*, *mottled bays*, and *dark bays*.

BAY. When a stag has been so long pursued, that, finding his strength nearly exhausted, he turns round, and, placing his haunches against some tree or wall, or anything, to prevent being surrounded, resolutely faces the hounds, keeping them *at bay* with his horns, till the sportsmen come up; when they are drawn off, and the deer is saved from destruction. When a deer takes *soil* (that is, plunges into the water) he will defend himself, and keep the hounds a long time *at bay*, provided he fathoms the lake or river so well as to keep the hounds swimming, and not go out of his own depth; if he loses which, and is obliged to swim, he is inevitably drowned by his numerous determined foes.

In fox hunting, when the fox takes to earth, which will be ascertained by the terrier lying well at him, provided the fox has not turned in the earth, in which case, and they are face to face, they are both *baying*, or keeping each other *at bay* till the fox is dug out.

BAY BOLTON was got by Grey Hautboy in 1705, and was bred by Sir M. Pierson.—He subsequently became the property of the Duke of Bolton.—In 1710, when five years old, he won the gold cup at York, beating eight 6 years old—a circumstance of rare occurrence: he also won two matches of Mr. Frampton's celebrated Dragon; after which he was kept as a stallion, and was the sire of Sloven, Fearnought, Starling, Syphax, Camilla, Gipse, and Whitefoot. He died at Bolton Hall, Yorkshire, 1736, aged 31;—he was a capital runner, and proved an excellent stallion.

BAY BOLTON. Bred by Mr. Vernon; foaled in 1777: got by Matchem, dam by Regulus, out of an own sister to the Ancaster Starling. He was long in the possession of his late Majesty George III. and was for many years the favourite stallion at Hampton court.

BAY MALTON. Bred by the Marquis of Rockingham; foaled in 1760; got by Sampson, dam by Cade, and grandam by Old Traveller. It is supposed that he never covered as a stallion, or if he did, he produced no horses of note. He won more prizes of consequence and value than any horse of his time.

BEAGLE. A beagle is the smallest of the hound tribe, and principally, if not altogether, used in the pursuit of the hare. All those who have written on the subject of beagles, have never been sufficiently definite in their mode of expression, as to give a clear

## B E A G L E

idea of the animal to those who were not previously acquainted with it: for the word beagle, although it designates the smallest kind of hound, also signifies one of such a peculiar formation, as to be obvious at first view. Thus, the animal under consideration is remarkable for an elongated form, and short legs; and it presents to the eye altogether the appearance of a dwarf hound. Although the talbot, or Old English blood hound may be very justly considered as the original stock, whence have sprung all the various ramifications which we see at the present day, yet the peculiar cross which produced the beagle is now unknown. They were originally employed for the purpose of coursing: they would trail a hare to her form, or, by opening, give notice that one was at no great distance. This was not exactly a fair mode of sporting, as the hare was certainly overmatched when a beagle was employed with greyhounds; as, if she made her way into a thicket or otherwise blinked her long-legged pursuers, she was still very liable to be started again by the beagle, in which case her destruction was certain. On this account beagles were laid aside by honourable sportsmen, as far as related to coursing; and those who might be considered as pot-hunters thus became ashamed of a practice which they saw despised by those who sought diversion fairly.

The beagle, however, was too interesting an animal to be altogether abandoned; and though he was withdrawn from the assistance of the greyhound, he was nevertheless adopted in the chase of the hare; beagles were formed into regular packs, and their hunting is not only highly interesting from their diminutive form, but from the busy ardour which they manifest in the pursuit. It has been generally supposed that beagles are very slow in the chase, which is certainly a very mistaken notion; and those who have propagated such an idea have never seen them run, but formed their opinion from the diminutive size of the hound: they are not so swift as the fox hound, or yet as the sharp-nosed northern harrier, but they are superior in speed to the southern hound; and, if they are well-bred, will generally kill a hare in about an hour, or with a good scent, in much less time. On this subject, a writer has remarked, "beagles, rough and smooth, have their admirers; their tongues are musical, and they go faster than the southern hounds, but tail much. They run so close to the ground as to enjoy the scent much better than taller dogs, especially when the atmosphere lies low. In an inclosed country (continues the writer) they do best, as they are good at trailing or default, and for hedge-rows; but they require a clever huntsman; for, out of eighty couple in the field, during a winter's sport (he observes) not four couple could be depended on." Of the two sorts, he prefers the wire-haired, as having good shoulders and being well filleted. "Smooth haired beagles (he continues) are commonly deep hung, thick lipped, with large nostrils, but often so soft and bad quartered as to be shoulder-shook and crippled the first season they hunt; crooked legs, like the Bath turnspit, are frequently seen among them; after two hours' running, many of them are disabled, and the

hunter may proceed to hunt the hare himself, for he will never receive any assistance from the greater part of them ; their form and shape sufficiently denote them not to be made for hard exercise." Now, all this rhodomontade amounts to this, that the writer possessed little knowledge of a subject, on which he so confidently expressed an opinion ; and that the crude notion which he had thus formed, was founded upon individuals which he perhaps had seen, but which, supposing his estimate correct, were exceedingly ill-bred animals. It is very well known, that no creature is more susceptible of change than the dog ; and the beagle, like all other varieties, may be bred (comparatively speaking) to any size, or any quality. There are " beagles, rough or smooth ;" though the nature of the coat has, in all probability, but little influence on the quality of the dog ; there are excellent animals of both kinds ; but the latter are much more general, and, if appearance alone be consulted, certainly preferable. Good sized bony beagles (about twelve inches in height) are admirably calculated for the pursuit of the hare ; they should have large heads, chubby rather than long, as, thus formed, they cannot fail to possess exquisite olfactory organs (a small narrow head in a dog is incompatible with a good nose) ; ten or twelve couple of these form a good pack, with musical voices (for the size of the head will be found to have much influence on the cry) ; and if two or three small southern hounds be added (or small hounds, with much of the southern blood) it will render the cry more melodious and more delightful. Where the writer above-quoted, says, " they run so close to the ground, as to enjoy the scent better than taller dogs," evinces at once his ignorance of the subject, as hounds of any kind never run so well or so sure, as when they can carry a good head ; or, in other words, when they can run breast high. It may seem paradoxical in expression, but when the scent is said to lie well, it rises from the ground, as it were, and thus the dog is enabled to follow his game without putting his nose to the ground. As to beagles being " good at trailing or default," this entirely depends upon their noses, and the manner in which they are bred ; and this remark will be found equally applicable to all kinds of hounds. It has been already observed, that the manner in which the beagle was originally produced is at present unknown ; but those who are desirous of procuring these interesting little hounds, may suit their own taste as to size, strength, &c. as they are to be met with, in great variety, in almost all parts of the kingdom. The large bony beagle, mentioned above, is well calculated to endure fatigue, and to shew good sport, while the smaller kinds will not answer so well ; and as to the very smallest, distinguished by the name of the lap-dog beagle, though they are very pretty in appearance, and may occasionally kill a hare, yet ultimate satisfaction cannot be expected from their exertions. Finally, if an opinion is to be formed from the appearance of the animal of the cross whence sprung the dog under consideration, it might seem that the deep-mouthed hound, and something of the turnspit breed, had been the original progenitors.

**BEAM**, in the head of a deer, is the basis, or part bearing the antlers, royals, and tops.

**BEAM FEATHERS**, are the long feathers of a hawk's wing.

**BEAR**. The bear is an animal, which is occasionally exhibited in this country in a very grotesque attitude for the amusement of children and the vulgar. As to bear-baiting, it has been for some time on the decline, and will, in all probability, at no distant period, be utterly extinct. Of this animal, there are three different kinds, the brown bear of the Alps, the black bear of North America, which is smaller, and the great Greenland white bear. These, though different in their forms, are most likely of the same original, and owe their chief variations to food and climate. They have all the same habitudes, being equally carnivorous, treacherous, and cruel; and it must, at the same time, be observed that brown as well as black bears are found in America, while to those of Europe the same remark may be equally applied. At all events, the bear tribe are all remarkable for having the soles of the feet very long, extending completely to the heel, which gives them a very firm tread. From the length and sharpness of their claws, they are all able to climb trees in search of prey, or to escape from their enemies.

The black and brown, or common bears, are inhabitants of the forests in the Northern regions of Europe, will feed on either animal or vegetable substances, and are said to be particularly fond of honey. In search of this, they climb trees in order to get at the nests of wild bees. The bear will also catch and devour fish; and occasionally frequents the banks of rivers for that purpose. He is a savage and solitary animal, living in the most retired and unfrequented parts of the forest. Here it retires alone, and passes some months of the winter without provisions, or without stirring abroad. However, this animal is not entirely deprived of sensation, like the bat or the dormouse, but seems rather to subsist upon the exuberance of its former flesh; and only feels the calls of appetite when the fat it had acquired in summer begins to be entirely wasted away. In this manner, when the bear retires to its den to hide for the winter, it is extremely fat; but at the end of forty or fifty days, when it comes forth to seek for fresh nourishment, it seems to have slept all its flesh away. It is a common report, that, during this time, they live by sucking their paws, which is a vulgar error that scarcely re-

quires confutation. These solitary animals couple in autumn, but the time of gestation with the female is not well known;—the female takes great care to provide a proper retreat for her young. The male and female by no means inhabit the same den; they have each their separate retreat, and are seldom seen together but upon the accesses of genial desire.

The voice of the bear is a kind of growl, interrupted with rage, which is often capriciously exerted; and though this animal seems gentle and placid to its master, when tamed, yet it is still to be distrusted and managed with caution, as it is often treacherous and resentful without cause. But, notwithstanding the fierceness of this animal, the natives of those countries where it is found, hunt it with great perseverance and alacrity. The least dangerous method of taking it is by mixing brandy with honey and placing it in its way, by which it will speedily become intoxicated. In Canada, where black bears are very common, and where their dens are frequently made in trees that are hollow towards the top, they are taken by setting fire to their retreat, which are often above thirty feet from the ground. By this means the bear is forced to shew himself, and is shot by the hunters.

The Indian tribes adopt the most singular ceremonies in their chase of the bear, of which Charlevoix, in his *Travels in North America*, gives the following account:—"The chase of these animals is a matter of the first importance, and is never undertaken without abundance of ceremony. A principal warrior first gives a general invitation to all the hunters. This is followed by a most strict fast of eight days, a total abstinence from all kinds of food; notwithstanding which the day is passed in continual song. This is done to invoke the spirits of the woods to direct the hunters to the places where there are abundance of bears. They even cut the flesh in divers parts of their bodies to render the spirits more propitious. They also address themselves to the manes of the beasts slain in the preceding chases, as if these were to direct them in their dreams to plenty of game. One dreamer alone cannot determine the place of the chase; numbers must concur; but as they tell each other their dreams, they never fail to agree. This may arise either from contrivance, or from a real agreement in their dreams, on account of their thoughts being perpetually turned on the same thing. The chief of the hunt now gives

a great feast, at which no one dares to appear without first bathing. At this entertainment they eat with great moderation, contrary to their usual custom. The master of the feast touches nothing; but relates to the guests ancient tales of the wonderful feats of former chases; and fresh invocations to the manes of the deceased bears conclude the whole. They then sally forth amidst the acclamations of the village; equipped as if for war, and painted black. Every able hunter is on a level with a great warrior; but he must have killed his dozen great beasts before his character is established; after which his alliance is as much courted as that of the most valiant captain. They now proceed on their way in a direct line; neither rivers, marshes, nor other impediments stop their course, driving before them all the beasts they find. When they arrive at the hunting ground, they surround as large a space as they can with their company; and then contract their circle, searching at the same time every hollow tree, and every place fit for the retreat of a bear: and they continue the same practice till the time of the chase is expired. As soon as a bear is killed a hunter puts into his mouth a lighted pipe of tobacco, and blowing into it fills the throat with the smoke, conjuring the spirit of the animal not to resent what they are going to do to its body, nor to render their future chases unsuccessful. As the beast makes no reply, they cut out the string of his tongue, and throw it into the fire. If it crackles and shrivels up (which it is almost sure to do) they accept it as a good omen; if not, they consider that the spirit of the bear is not appeased, and that the chase of the next year will be unfortunate. The hunters live well during the chase on provisions which they bring with them. They return home with great pride and self-complacency; for to kill a bear forms the character of a complete man. They give a great entertainment, at which they make it a point to leave nothing uneaten. The feast is dedicated to a certain genius (apparently that of gluttony) whose resentment they dread if they do not eat every morsel, and even sup up the melted grease in which the meat was dressed. They sometimes eat till they burst, or bring on themselves some violent disorder. The first course is, the greatest bear they have killed; without even taking out the entrails or skinning it; contenting themselves with singeing the skin, as is practised with hogs."

The bear is by no means deficient in

courage, and never fails to make every possible resistance. A number of extraordinary recitals have been published by the Americans respecting their encounters with bears, some of which, it must be confessed, seem to partake somewhat of that hyperbole for which the transatlantic republicans are so celebrated. The following, however, may be received as authentic perhaps, as Campbell has related it in his *Travels in North America*. A gentleman and his son (near a house in which the author then lodged, on Spoon Island) had been out at hay making, and were luckily armed with pitchforks; and seeing a monstrous bear quite close to the river, they pressed so hard upon him as to drive him into the water. They then thought they had him secure, as there was a boat near them, to which they immediately ran, and having pursued and come up with him, they struck and pelted him with the pitch forks and shafts till they were broken in pieces. The exasperated monster now, as they had no weapon to annoy him, turned the chase on his adversaries, and, fixing his paws on the gunnel of the boat, attempted to get in. They did all they could to keep him out, but their efforts were in vain. He got in: thus circumstanced, they had their choice either to jump into the water, or continue in the boat and be torn to pieces: they chose the former and swam ashore. The bear made no attempt to follow, but continued in the boat; and, seeing the animal so calm, they ran immediately to the house for guns; and, upon their return, found him sitting in the boat, dipping one of his paws now and then in the water, and washing his wounds: on which, levelling their pieces, they shot him dead. The landlord of the house where this recital was given, showed one of the paws of this bear, which, on account of its great size, he kept as a curiosity; and added, that the bear was as big as a yearling calf.

The modern Russian method of hunting the bear differs very much from the mode just described, and is worthy of recital for two reasons: viz. in the first place, it is little known in this country; secondly, it exhibits a curious contrast, as well as shows some very singular characteristics of this animal. In winter, when bears are extremely sluggish, the hunters approach the den of the bear, which is generally formed in some thicket; and, cutting a sort of avenue before and behind it, sufficient for bruin to pass along, they line each side of it with a simple net; and

such is the animal's aversion to any thing which appears like a toil, that he will not even attempt to break through what could not resist his force for one moment: part of the company place themselves in ambush at the front end of the avenue, while the other go behind, and make as much noise as possible, to drive him in the opposite direction; when he is either shot, or killed by the spear.

An instance is also given of a Russian huntsman, who, having strayed some distance from his companions, was met by a very large bear. The noise made by the man and the bear drew the hunting party to the spot, when they beheld a monstrous bear on his hind legs fighting with the man, who unfortunately happened to be without his *couteau de chasse*, the usual and useful weapon upon such occasions. The fellow held the bear, though taller than himself, by the ear, at arm's length, and with his left hand was striking him on the opposite side the head, every time he offered to bite or claw the extended arm, which prevented his being hugged. Count Alexy Rossomofsky, alarmed for the safety of the huntsman, desired that he would let go the animal, that some of the party might shoot him; but the hardy Russian said *the bear was only in joke*, though he had then clawed his face in such a manner, that none of them knew which of the men it was who was thus engaged in single combat. At this moment, a number of his companions came running up, and, instead of attempting to kill the bear, instantly took off their belts, and, coming behind him, still struggling with their comrade, and growling as a bear always does when he is attacked, slipped one belt into his mouth, and two more round his body, and thus completely subdued and took him alive.

Another curious circumstance attending a Russian bear hunt, is the manner in which the peasants trace these animals out in summer, by what may sportingly be called their *seat* or *form*. Though the bear will commit depredations on the flock, he is, nevertheless, fond of green corn, and makes havoc amongst the growing crops: his manner of feeding is remarkable, and in this act he makes what the peasants call his *form*, and by which they trace him from one part to another. When a bear finds a field of corn to his taste, either in the milky or ripe state of the grain, he chooses a soft spot amongst it, where he sits on his buttocks, and eats round him as far as he can reach, turning on his seat

as a centre, and thus makes an indention in the earth, round and smooth, like a large basin. Hence the peasants ascertain the size of his hind quarters; and, measuring from that the cropped circle of the corn, they judge of his length. The lazy animal, it seems, eats all around him as far as he can reach, when, removing to a fresh spot, he again devours in the same manner. These forms, by the comparative freshness of their appearance, apprise his pursuers of their approach to the animal. Thus the bear is generally discovered in summer, and shot. When no more than three take the field in pursuit of a bear, the following mode is adopted: as soon as the bear is found, the three take their stations at a certain distance and direction from each other; one of them fires at the animal, on which he immediately makes towards him; the second then fires, to draw him to the other side; and the third does the same, to give him a third direction. By the time these manœuvres are executed, the first sportsman has again loaded; and in this manner they load and fire alternately, till they have despatched their game.

In Finland the chase of the bear is very different. The Finns erect, about the middle of a tree, in the bear's favourite haunts, a small round scaffold, much in the style of one of the tops of a ship. On this a man takes his station, and patiently awaits the approach of bruin to the foot of the tree, (attracted by honey or other favourite food placed there as a bait) and shoots at him through holes made for that purpose in his stage. If the animal be not disabled, he furiously mounts the tree, but is stopped in his course by the round top, and the hunter of course has a most favourable opportunity of despatching him, being armed with an axe to chop off the bear's paws, should they appear above the stage in attempting to mount it.

If the bear ever existed in this country in a state of unlimited freedom, it must have been at a period very remote, though the chase of this animal is thus described in some of the old sporting-book. If they be hunted, they will follow a man, but not run upon him unless they are wounded. They are very strong in their paws, in such sort, that they will so hug a man or dog, as to break his back, or squeeze his guts out of his belly: with a single paw they will pull a dog to their tearing and devouring mouth. They bite very severely; for they will bite a man's head to the very brains; and for an arm or leg,

they will crush it as a dog may do a slender bone of mutton.

When they are hunted, they are so heavy that they make no speed, and so are always in sight of the dogs: they stand not at bay as a boar, but fly wallowing; but if the hounds stick in, they will fight valiantly in their own defence; sometimes they stand up straight on their hinder feet; and then take that as a sign of fear and cowardice; they fight strongest and stoutest on all four.

They have an excellent scent, and smell further off than any other beast except the boar; for in a whole forest they will smell out a tree laden with mast.

They may be hunted with hounds, mastiffs, or greyhounds; and they are chased and killed with bows, bear spears, darts, and swords; so they are also taken in snares, caves, pits, and other engines.

They go sometimes a gallop, at other times an amble; but they go most at ease when they wallow. When they come from their feeding, they beat commonly the highways and beaten paths; and where-soever they go out of the highways, there you may be sure they are gone to their dens; for they use no doublings nor subtleties.

The best finding of a bear is with a lame hound; and yet he who is without one may trail after a bear as we do after a buck or roe, and you may lodge and hunt them as you do a buck. For the more speedy execution, mingle mastiffs with your hounds; for they will pinch the bear, and so provoke her to anger, until at last they bring her to the bay, or else drive her out of the plain into the covert, not letting her be at rest till she fight in her own defence. Such is the language of the sportsmen of former periods.

Bears are found in almost all the Alpine and mountainous regions of continental Europe (and indeed in most parts of the world); they are not often hunted, at least not in a formal manner; but they are apt to commit depredations on the flock, (and when pressed by hunger will even attack men), as well as sometimes destroy children; they are shot as often as an opportunity offers.

It is well known that the bear may, with some little difficulty, be rendered tame and docile; and it has then the appearance of being mild and obedient to its master; but it is not to be trusted without caution. It may be taught to walk on its hind feet, lay hold of a pole with its fore

paws, and perform various tricks to entertain the multitude, who are highly pleased with the awkward measures of this rugged animal, which it seems to suit to the sound of an instrument, or to the voice of its leader. But to give the bear this kind of education, it is necessary to have it taken young, and to accustom it early to restraint and discipline. An old bear will suffer no restraint without manifesting the most furious resentment: neither the voice nor the menaces of his keeper have any effect upon him; he equally growls at the hand that is held out to feed, and at that which is raised to correct, him.

It must be admitted, however, that much cruelty is practised in teaching this animal to walk upright, and to regulate its motions to the sound of the pipe. Bear-baiting is now but little practised; and the reader need hardly be told, that in this diversion the bear was fastened to a stake, having about six or eight yards of loose rope, which enabled the animal to describe a considerable circle, and allowed it sufficient room for the exercise of its strength, and consequently for its defence against its assailants. Bull-dogs are the best calculated for the purpose; and indeed a dog will not face a bear unless he is bred very near the bull-dog, if we except the mastiff, some of which will run at the bear, while others will refuse; and consequently entire dependance cannot be placed upon them. A bear is more than a match for either bull-dog or mastiff singly; but two good dogs of either kind would very soon destroy him.

The white Greenland polar bear differs greatly, both in figure and dimensions, from those already described; and though it preserves in general the external form of its more southern kindred, yet it frequently grows to double the size. The brown bear is made rather strong and sturdy; the Greenland bear, on the contrary, though covered with very long hair, and apparently bulky, is nevertheless more slender; in short, all the variations of its figure and colour seem to proceed from the coldness of the climate where it resides, and the nature of the food it is supplied with.

The polar bears are animals of tremendous fierceness and strength. Barentz, in his voyage in search of a north-east passage to China, witnessed the most horrid proofs of their ferocity in the island of Nova Zembla, where they attacked his seamen, seizing them in their mouths, carrying them off with the utmost ease, and

devouring them even in the sight of their comrades.

Not many years ago, the crew of a boat belonging to a ship in the whale fishery shot at a white bear, and wounded it. The animal immediately set up the most dreadful howl, and ran along the ice towards the boat. Before he reached it, a second shot was fired, which hit him. This served but to increase his fury. He presently swam to the boat, and, in attempting to get on board, placed one of his fore feet upon the gunnel; but a sailor, having a hatchet in his hand, cut it off. The animal still, however, continued to swim after them till they arrived at the ship; and several shots were fired at him which took effect; but, on reaching the ship, he immediately ascended the deck; and the crew having fled into the shrouds, he was pursuing them thither, when a shot laid him dead upon the deck.

The usual food of these animals consists of seals, fish, and the carcasses of whales; but when on land, they prey on deer and other animals, as hares, young birds, &c. They likewise eat various kinds of berries which they happen to find. They go on the flakes of ice in search of seals, and also attack the arctic walrus; but this creature makes a gallant defence with its long tusks, and sometimes comes off victorious. They are said to be frequently seen in Greenland in great droves, allured by the smell of the flesh of seals; and they will sometimes surround the habitations of the natives, and attempt to break in; when, it is added, the most successful method of repelling them is the smell of burnt feathers.

The affection between the parent and the young is so great, that they will sooner die than desert each other in distress. Cartwright, in his *Journal of a Residence on the Coast of Labrador*, particularly mentions this circumstance, and says that it is highly dangerous to shoot the cub of a white bear, unless you first destroy the dam, as she will not fail to attack you with the utmost fury the moment she perceives her cub to be wounded. The following is a striking instance of the maternal affection of these animals: While the *Carcass Frigate*, which went out some years ago to make discoveries towards the North Pole, was locked in the ice, early one morning the man at the mast head gave notice that three bears were making their way very fast over the frozen ocean, and were directing their course towards the ship. They had no doubt been invited by

the scent of some blubber of a sea-horse, which the crew had killed some days before, and which had been set on fire, and was burning on the ice at the time of their approach. They proved to be a she bear and her two cubs; but the cubs were nearly as large as the dam. They ran eagerly to the fire, and drew out of the flames part of the flesh of the sea-horse, that remained unconsumed, and devoured it voraciously. The crew from the ship threw great lumps of the flesh of the sea-horse, which they had still remaining, upon the ice: these the old bear fetched away singly, laid every lump before the cubs as she brought it, and, dividing it, gave to each a share, reserving only a small portion for herself. As she was fetching away the last piece, the sailors levelled their muskets at the cubs, and shot them both dead; and in her retreat they wounded the dam, but not mortally. It would have drawn tears of pity from any but unfeeling minds, to have marked the affectionate concern expressed by the poor beast in the last moments of her expiring young. Though she was herself dreadfully wounded, and could but just crawl to the place where they lay, she carried the lump of flesh which she had fetched away, as she had done before, tore it in pieces, and laid it before her young; and when she saw that they refused to eat, she laid her paws first upon one, and then upon the other, and endeavoured to raise them up. All this while, it was pitiful to hear her moan. When she found she could not stir them, she went off, and when she had got to some distance, looked back and moaned; and that not availing her to entice them away, she returned, and smelling round them, began to lick their wounds. She went off a second time as before, and, having crawled a few paces, looked again behind her, and for some time stood moaning: but still her cubs not rising to follow her, she returned to them again, and with signs of inexpressible fondness went round, pawing them and moaning. Finding, at last, that they were cold and lifeless, she raised her head towards the ship, and uttered a growl of despair, which the seamen returned with a volley of musketry. She fell between her cubs, and died licking their wounds.

Mr. Hearne says that the males of the polar bear are so much attached to their mates, that he has seen one of them, when a female was killed, come and put his two fore paws over her, and in this position suffer himself to be shot rather than quit her.

White bears are sometimes found in Iceland; but not being natives of the island, they are supposed to have floated from the opposite coast of Greenland on some of the huge masses of ice that are detached from those shores. After so long an abstinence as they must necessarily have undergone in the voyage, they are reduced by hunger to attack even man, should he come in their way. But Mr. Horrebrow informs us, that the natives are always able to escape their fury, if they can throw in their way something to amuse them. A glove (he says) is very proper for the purpose; for the bear will not stir till he has turned every finger of it inside out, and this takes up sufficient time to afford the man to escape.

During the winter these animals retire, and bed themselves deep in the snow, or under the fixed ice of some eminence, where they pass, in a state of torpidity, the long and dismal arctic night, and re-appear only with the return of the sun.

They grow exceedingly fat, one hundred pounds weight of that substance having been taken from a single bear.

**BEAR-BAITING.** In baiting the bear, he is generally fastened to a stake or post by a chain passed round his body, allowing him sufficient liberty to defend himself from the dogs, which are then let loose at him.

**BEARING-REIN.** See **HARNESS.**

**BEASTS** of the **FOREST**, are the hart, the hind, the hare, the boar, and the wolf.

**BEASTS** of the **CHASE**, are the buck, the doe, the fox, the roe, and the marten.

**BEASTS** and **FOWLS** of **WARREN**, are the hare, the coney, the pheasant, and the partridge.

**BEAT.** *To beat* is a term used of a stag, which runs first one way, and then another; he is then said *to beat* up and down. Also, the noise made by coneys in rutting time, which is called beating or tapping. In *Coursing*, *to beat* for a hare is endeavouring to start one, in which case people generally beat the hedges and covers with sticks or staves.

**BEAVER.** The beaver is a native of most of the northern parts of Europe and Asia, but is principally found in North America. There is reason to suppose that it was once an inhabitant of Great Britain, as Geraldus Cambrensis says, that these animals frequented the River Tievi, in Cardiganshire, and that they had from the Welsh a name, signifying "the broad-tailed animals." The skins were valued by the laws of Howel Dda, in the tenth century,

at the great sum of a hundred and twenty pence each; and they seem to have constituted the chief finery and luxury of those days. The general length of the beaver is about three feet. The tail is oval, nearly a foot long, and compressed horizontally, but rising into a convexity on its upper surface: it is perfectly destitute of hair, except at the base, and is marked out into scaly divisions, like the skin of a fish. The hair is very fine, smooth, glossy, and of a chestnut colour, varying sometimes to black; and instances have occurred in which these animals have been found white, cream-coloured, or spotted. The ears are short, and almost hidden in the fur.

No other quadrupeds seem to possess so great a degree of natural sagacity as the beavers. The front teeth of this animal are very strong, and well adapted to the purpose of gnawing wood. They feed on leaves, and the bark of trees; and when they eat, they sit upright, and carry the food to their mouth in the same manner as the squirrel tribe; and it has been proved that the beaver subsists wholly on vegetable substances, and will eat no animal food whatever.

Beavers generally live in associated communities of two or three hundred, inhabiting dwellings which they raise to the height of six or eight feet above the water. They select, if possible, a large pond, in which they raise their houses on piles, forming them either of a circular or oval shape, with arched tops, thus giving them, on the outside, the appearance of a dome, while they within somewhat resemble an oven. The number of houses is in general from ten to thirty. If the animals cannot find a pond to their liking, they fix on some flat piece of ground with a stream running through it. In making this a suitable place for their habitations, a degree of sagacity and intelligence, of intention and memory, is exhibited, approaching, in an extraordinary degree, to the faculties of the human race. The first object is, to form a dam. To do this, it is necessary they should stop the stream, and, of course, that they should know in which direction it runs. This seems a wonderful exertion of intellect, as they always do it in the most favourable place for their purpose, and never begin at a wrong part. They drive stakes five or six feet long into the ground, in different rows, and interweave them with branches of trees, filling them up with clay, stones, and sand, which they ram so firmly down, that, though the dams are frequently a hundred feet long, they

will bear a great weight, and Cartwright says he has walked over them with the greatest safety. These are ten or twelve feet thick at the base, gradually diminishing towards the top, which is seldom more than two or three feet across. They are exactly level from end to end, perpendicular towards the stream, and sloped on the outside, where grass soon grows, and renders the earth more united.

The houses are constructed, with the utmost ingenuity, of earth, stones, and sticks, cemented together, and plastered on the inside with surprising neatness. The walls are about two feet thick, and the floors so much higher than the surface of the water, as always to prevent them from being flooded. Some of the houses have only one floor; others have three. The number of beavers in each house is from two to thirty. These sleep on the floor, which is strewn with leaves and moss; and each individual is said to have its own place. When they form a new settlement, they begin to build their houses in the summer; and it costs them a whole season to finish the work, and lay in their winter provisions, consisting principally of bark and the tender branches of trees, cut into certain lengths, and piled in heaps under the water.

The houses have each no more than one opening, which is under the water, and always below the thickness of the ice, by which means they are secured from the effects of frost. Beavers seldom quit their residence, unless they are disturbed, or their provisions fail. When they have continued in the same place three or four years, they frequently erect a new house annually, but sometimes merely repair their old one. It often happens that they build a new house so close to the old, that they cut a communication from one to the other; and this may have given rise to the idea of their having several apartments. When their houses are completely finished, they will carry on fresh works; nor do they desist even when the pond is frozen over, but continue their employments for some nights after (if the frost is not too severe) through a hole in the ice, which they keep open for the purpose.

During the summer they forsake their houses, and ramble about from place to place, sleeping under the covert of bushes near the water side. On the least noise, they betake themselves to the water for security; and they have sentinels, which, by a certain cry, give notice of the approach of danger. In the winter they

never stir out, except to their magazines under water; and during that season they become excessively fat.

The following is the account which Du Pratz gives of the beavers of Louisiana. At the head of one of the rivers of Louisiana he discovered a beaver dam. Not far from it, but hidden from the sight of the animals, he and his companions erected their hut, in order to watch the operations at leisure. They waited till the moon shone pretty bright; and then, carrying branches of trees in their front, to conceal themselves, they went with great care and silence to the dam. Du Pratz ordered one of the men to cut, as silently as possible, a gutter, about a foot wide, through it, and retire immediately to the hiding-place.

As soon as the water through the gutter began to make a noise, we heard (says the writer) a beaver come from one of the huts, and plunge in. We saw him get upon the bank, and clearly perceived that he examined it. He then, with all his force, gave four distinct blows with his tail, when immediately the whole colony threw themselves into the water, and arrived upon the dam. When they were all assembled, one of them appeared, by muttering, to issue some kind of orders; for they all instantly left the place, and went out on the banks of the pond in different directions. Those nearest to us were between our station and the dam, and therefore we could observe their operations very plainly. Some of them formed a substance resembling a kind of mortar; others carried this on their tails, which served as sledges for the purpose. I observed that they put themselves two and two, and that each of a couple loaded his fellow. They trailed the mortar, which was pretty stiff, quite to the dam, where others were stationed to take it; these put it into the gutter, and rammed it down with blows of their tails.

The noise of the water soon ceased, and the breach was completely repaired. One of the beavers then struck two blows with his tail; and instantly they all took to the water without noise, and disappeared.

M. Du Pratz and his companion afterwards retired to their hut to rest, and did not again disturb these industrious animals till the next day. In the morning, however, they went together to the dam to observe its construction, for which purpose it was necessary that they should cut a part of it down. The depression of the water in consequence of this, together with the

noise they made, roused the beavers again. The animals seemed much disturbed by these exertions; and one of them, in particular, was observed several times to come pretty near the labourers, as if to examine what passed. As M. Du Pratz apprehended that they might run into the woods if further disturbed, he advised his companions again to conceal themselves.

One of the beavers then ventured (continues our observer) to go upon the breach, after having several times approached and returned like a spy. He surveyed the place, and then struck four blows, as he did the preceding evening, with his tail. One of those that were going to work passed close by me; and as I wanted a specimen to examine, I shot him. The noise of the gun made them scamper off with greater speed than a hundred blows of the tail of their overseer could have done. By firing at them several times afterwards, they were compelled to run with precipitation into the woods. M. Du Pratz then examined their habitations.

Under one of the houses he found fifteen pieces of wood, with the bark in part gnawed off, apparently intended for food. Round the middle of this house, which formed a passage for them to go in and out at, he found no less than fifteen different cells. These habitations were made by posts fixed slantingly upwards to a point; and in the middle was the floor, resting firmly on notches in the posts.

Beavers bring forth their young towards the end of June, and generally have two at a time, which are, in nine instances out of ten, male and female. They continue with their parents till they are full three years old, when they pair off, and form houses for themselves. If, however, they are undisturbed, and have plenty of provisions, they remain with the old ones, and thus form a double society. Instances have occurred of beavers having been perfectly domesticated. Major Roderfort, of New York, related to Professor Kalm, that he had a tame beaver above half-a-year in his house, where he went about quite loose, like a dog. The major gave him bread, and sometimes *fish*, of which he was very fond. As much water was put into a bowl as he wanted. All the rags and soft things he could meet with, he dragged into the corner where he was accustomed to sleep, and made a bed of them. The cat in the house, having kittens, took possession of his bed; and he did not attempt to prevent her. When the cat went out, the beaver often took

the kitten between his fore paws, and held it to his breast, as if to warm it: he seemed to doat upon it; yet, as soon as the cat returned, he always restored to her the kitten. Sometimes he grumbled, but never attempted to bite.

The skin of the beaver has two kinds of hair: the lower, immediately next the hide, is short, implicated together, and as fine as down; the upper hair grows more sparingly, and is both thicker and longer. The latter is of little value; but the former is wrought into hats, and other articles of dress.

The hunters prefer the winter season for seeking out the habitation of the beavers. They stop up the entrance to them on the side next the water, with stakes, and enlarge the vent-hole which they find on the land side: this is done for the purpose of putting through it a dog, which is so trained that he holds the beaver with his teeth, and suffers himself to be drawn out by the hind legs. The Indians about Hudson's Bay first drain off the water of the dam, and then, covering the houses with nets, break in at the top; on which the affrighted beavers, running through the door to escape, become entangled in the meshes.

In some parts of Lapland, beavers are caught in traps made of the twigs of fir trees. The top of these the hunters fasten to a small branch of poplar, of which the animals are very fond. The beaver gnaws away this fastening, is let down, and caught. But it is remarked, that wherever two have been together, the one has always set the other at liberty. A good skin will weigh about two pounds.

The medicinal substance called *castor* is produced in the inguinal glands of these animals; and each individual, both male and female, has usually about two ounces. That produced by the Russian beavers is more valuable, and sells at a much higher price, than that which is imported from America. The flesh is good eating: it is usually preserved (the bones being first taken out) by drying it in the smoke.

It frequently happens that single beavers live by themselves in holes which they make in the banks of rivers, considerably under the surface of the water, working their way upward to the height of many feet. These are called by the hunters *hermits* or *terriers*. Like the rest, they lay up a store of provisions for the winter. It is supposed by Cartwright that their separation from society originates in attachment and fidelity; that, having by some accident lost their mate, they will

not readily pair again. Whatever may be the cause, it has been remarked, that they have invariably a black mark on the skin of their backs, which is called a saddle, and by which they are easily distinguished from the others.

Their motions on land are very slow; and being timid animals, they are easily killed, though possessing teeth so sharp and strong, as to enable them to make a stout resistance. If they happen to be met on land by a man, they sit down, and cry like a child.

The beaver is the only creature among quadrupeds that has a flat broad tail, covered with scales, which serves as a rudder to direct its motions in the water. It is the sole quadruped that has membranes between the toes on the hind feet only, and none on the fore feet, which supply the place of hands, as in the squirrel. In short, it is the only animal that in its fore parts entirely resembles a quadruped, and in its hind parts seems to approach the nature of fishes, by having a scaly tail. It is somewhat shaped like a rat, except the tail, which, as already observed, is flat and scaly, somewhat resembling a neat's tongue at the point.

**BED OF SNAKES.** A knot of young snakes. Also, a roe is said to bed when she lodges in a particular place.

**BEDDING.** On the bedding of horses, there has been a variety of opinions. Horses that work hard should always be well littered. During the day, the bedding or litter, should be removed; in fine weather it may be placed outside the door, so that it may be rendered dry and free from smell. A little straw should always be placed in the stall for the horse to stale upon, and this may be changed once a day. By thus drying the litter during the day, it will serve again as well as fresh straw for the bottom of the bed, and will be perfectly free from smell. A great saving may be made in litter by turning it out and drying it in this manner.

**BELLING, or BELLOWING.** The noise which deer make during the rutting season.

**BELLY-BAND.** See **HARNESS.**

**BEND, TO,** in archery signifies the putting on of the string so that it may be ready for immediate use.

**BETTING** is the act of laying a wager or making a deposit of money, by two persons of contrary opinions, for one to become the winner upon the decision of some popular or public event; and that so

fashionable a mode of terminating disputes may meet with but little difficulty or obstruction, bets are made with as much deliberation, and discharged by the sporting world with as much integrity, as the most important transactions of the commercial part of society in the first city in the universe. Betting indeed, in this country, has been reduced to a system, of which there are now many professors in existence. Where two opponents deposit each an equal sum (whether fifty, or five thousand pounds) upon any event whatever, it is then termed *an even bet*. An offer of *six to four*, implies the odds in direct ratio of six pounds to four, or twelve to eight, or in that proportion to any amount. Betting *two to one* is laying ten pounds to five, twenty to ten, and so on; one depositing exactly double the amount of his adversary's stake; three, four, and five to one, being regular in the same way. The latter are all termed *laying the odds*, which vary according to the predominant opinions of the best judges upon the probable termination of the event; one rule being invariable, the person betting *the odds* (or, in plainer language, the *larger* sum against the *smaller*) has always the privilege of taking his choice in preference to his adversary, against which no appeal can ever be made with a decision in its favour. Any person proposing *a bet* to another during the running of a horse, the fighting of a cock, or any other transaction, the party applied to saying "*done*," and the proposer replying "*done*" also, it then becomes a *confirmed bet*, and cannot, in sporting etiquette and honour, *be off*, or revoked, but by mutual consent. No bet *above ten pounds* can be sued for and recovered in our courts of law: the payment of all losings above that sum must depend entirely upon the *sporting integrity* of the parties concerned.

A bet made after the heat is over, if the horse betted on does not start again, is no bet.

A confirmed bet cannot be off without mutual consent.

Either party may demand stakes to be made; and, upon refusal, may declare the bet void.

A bet made upon a race, if the party be absent on the day of running, the public declaration of the bet may be made on the course, and a demand whether any person will make stakes for the absent party; if no person consent to do so, the bet may be declared void.

Bets agreed to be settled in town, or

any particular place, cannot be declared off on the course.

If odds are bet without mentioning the horse before the race is over, it must be determined as the odds were at the time of making it.

Bets made in running are not determined till the plate is won, if that heat be not specified at the time of betting.

Bets made between particular horses are void if neither of them be the winner, unless specified to the contrary.

At Newmarket, if a match be made for any particular day in any meeting, and the parties afterwards change the day, all bets must stand; but if altered to a different meeting, bets made before the alteration are void.

Bets determined, though the horse does not start, when the words "absolutely," "run or pay," or "play or pay," are made use of in betting.

All double bets are considered as *play or pay*.

Since Epsom Races, 1822, all bets are made in pounds, and not in guineas, as formerly.

Bets made on horses winning any number of plates that year, remain in force till the first day of May.

Money given to have a bet laid, not returned if not run; the same rule of course in regard to cock fighting, &c.

All bets are void on the decease of either party, before determined.

BEVY of ROE-DEER. A herd or company of those animals.

BEVY of QUAILS is a term used for a flock or brood of those birds.

BEWITS. A piece of leather to which a hawk's bells are fastened and buttoned to her legs.

BILLETING. The dung of a fox.

BINDING. A term used in tiring, or when a hawk seizes her prey.

BIRD-LIME is a well-known viscid substance, prepared in different ways, from a variety of materials, chiefly vegetable, and is used for catching birds, mice, or any other small animals.

In England, bird-lime is generally made from holly bark, though we possess a number of plants from which it may also be obtained, such as mistletoe, the root of the hyacinth, of the asphodels, the narcissus, and the black bryony, and the young shoot of the elder tree: it may likewise be made from animal substances. M. Barrera, a physician of Perpignan, having discovered the means of preparing it from the bolls of a sort of caterpillar, by putre-

fying them in the earth, steeping them in water, and then pounding and mixing them with olive oil.

The bird-lime brought from Spain has an unpleasant smell; that brought from Damascus will stand neither frost nor wet; that of the Italians is better and is made of the berries of the mistletoe, though none of them is equal to that manufactured in England, and which is made as follows:—take a quantity of holly-bark, and, having cleaned it from a thin brown scurf which is frequently found on the outside, boil it in a kettle of water for ten or twelve hours till the green coat is separated from the other: it is then covered up for a fortnight in a moist place, next pounded into a rough paste so that no fibres of the wood be left, after which it is washed in a running stream till it be perfectly free from all impurities; it is now put up to ferment for four or five days, skimming it as often as anything rises, and then laid up for use: a third part of sweet oil or any thin grease must be mixed with it when used.

As bird-lime is apt to be congealed and rendered useless in frosty weather, a portion of petroleum ought to be incorporated with it during the cold seasons; as likewise it loses its force by being exposed to the wet; a particular sort called water bird-lime should be used in marshy places; it is prepared as follows:—Take a pound of strong good bird-lime, wash it thoroughly in spring water till the hardness be entirely removed, beat it well, to separate the water from it, and then dry it well and put it into an earthen pot, add to it as much capon's grease as will make it run; then add one spoonful of strong vinegar, one spoonful of oil and a small quantity of Venice turpentine. Let the whole boil for some minutes over a moderate fire, stirring it all the time, then take it off, and when there is occasion to use it, warm it and cover the sticks well with it.

The method of preparing twigs with the common bird-lime, is to make it hot, and dip the ends of a bundle of rods into it, then to turn them about and play them together till a sufficient quantity is extended over them all: this, however, though the general custom, makes but clumsy work; the following being a much neater mode of applying it; first rub both your hands over with oil to prevent the bird-lime from sticking to them; next take a piece about the size of a nut between the thumb and two fingers of the left hand, whilst in the right you hold the twig; begin by twisting it in the bird-lime till you

have covered it from within a hand's breadth of the thicker end up to the point: when you think you have limed it sufficiently well, roll the rod between your hands so as to make them look more even and neat.

The best twigs are those cut from the willow tree, as they have a smoother bark, and are freer from knots than any other kind; the thicker ends ought to be cut to a point and hardened in the fire, in order that they may more readily be stuck into the ground.

Strings or cords may also be limed in this manner, or by dipping them into the bird-lime while very hot, as may also straws: when thus prepared, they should be preserved in a leather bag till wanted.

**BISHOPPING**, an operation performed on the mouths of horses, &c. by dealers, with a view of passing them off for young animals when the natural marks are obliterated.

The front teeth, or incisores, of both jaws, in a young horse, meet exactly in a line, and perpendicularly to each other.—As the horse grows older, these teeth take a more horizontal direction, nearly in a line with the jaws, the upper teeth projecting very considerably over the lower teeth; at the same time the upper corner tooth forms a curve over the lower corner tooth. Furrows appear on their front surfaces, and their colour becomes yellow and opaque. Other characteristics of age may be seen externally; for instance, the eyes sink in their orbits, the eye-lids become lean and wrinkled, and the cavity above the eye appears more hollow (this cavity, however, is sometimes deep in a young horse). Grey hairs shoot out upon the forehead and the lower part of the mouth, the middle of the nose becomes indented by the long continued pressure of the nose-band of the head-collar, and the lips exhibit a lean and shrivelled appearance, the lower lip hanging considerably below the upper lip. The ears also drop more or less in a lateral direction.—These external marks of old age, together with those of the teeth, the dealer in horses exerts his ingenuity to counteract.

He, therefore, commences his operations by making an opening between the skin and cellular membrane, at a small distance above the eye, into which he introduces a quill, and by blowing into it, fills up the cavity and gives it a plump appearance. He proceeds next to furnish the corner teeth with the same marks which they possessed at seven years old.

For this purpose, he forms an artificial cavity in the head of the tooth with an engraving tool, and gives it a black colour by burning it with a hot iron. This process, in the stable vocabulary, is called bishopping. By such practices as these, an inexperienced person may be deceived; but, by attending to the following observations, the imposition may be easily detected; for, although the dealer has it in his power to make marks or cavities in the corner teeth, yet he cannot alter their horizontal direction, nor restore them to the perpendicular approximation which is the attendant of youth. Neither can he re-produce the prominence of the ridges of the roof of the mouth, nor furnish the tushes with their original concave surfaces. As it suits the purpose of the dealer to make an old horse appear younger, so does he sometimes find it convenient to make a young horse appear older. A horse is more saleable at five years old than at four, on which account the dealer attempts to produce an additional year, by drawing the corner teeth before the natural period of their dropping out. The bars of the mouth are also cut, to let the tushes protrude prematurely.—But although the corner teeth are removed, and the protrusion of the new teeth is thereby somewhat accelerated, yet it is an unerring rule, that the animal has not attained his fifth year until the corner teeth, both of the upper and lower jaw, are complete in their size and appearance, and the marks of the middle teeth begin to fill up. The tushes also should rise considerably above the jaw.

It is difficult to discover with accuracy the age of *crib-biters*, and horses whose teeth are extremely hard: the former lose the marks of their teeth before their usual period, the latter retain them long after the age of seven years. In examining a horse's mouth, it is necessary to look at both sides of it, as a considerable difference in the appearance frequently occurs from the mastication of the food being performed on one side of the mouth only, in which case the teeth on that side of the jaw which has most friction, will be most forward in their alteration.

**BITCH**. The female of the dog is so called: also the female fox is sometimes called a bitch-fox: vixen, is perhaps a more common term.

**BITES** frequently happen to dogs and sometimes to horses, by venomous insects and reptiles, some of which are not well known. The means of relief must, in

some degree, be regulated by appearances; and whenever inflammation is observed, bleeding cannot be otherwise than serviceable. Generally speaking, sweet oil (vegetable oil) will be found highly serviceable in cases of this kind, as an external application.—*See Adder.*

BITTERN, a bird of the crane or heron tribe, is rather smaller than the latter, being in length about two feet six inches; the bill is four inches long, of a greenish brown colour; the head feathers are long, and those of the neck loose and waving; the crown of the head black, the feathers on the hind part forming a sort of pendent crescent; the lower mandible on each side, dusky; the plumage is beautifully variegated; the ground a ferruginous yellow colour, palest beneath, marked with many bars, streaks, and numerous zig-zag lines of black; the feathers of the breast very long and loose, the legs are of a pale green; claws, long and slender, and the inner edge of the middle claw serrated, for the purpose of holding their prey more securely. The female is less than the male, darker coloured, and the feathers on the head and neck are shorter and less flowing. The bittern has somewhat the appearance of the heron, and, from the marshes being its favourite resort, it might reasonably enough be supposed that it would resemble the heron also in flavour; but this is not the case; on the contrary, while the fishy taste renders the heron altogether unpalatable and disgusting, the bittern is plump, and its flesh is somewhat similar, but superior in flavour, to that of the hare. In short, the heron is meagre and cadaverous, subsisting chiefly on fish; but the bittern feeds upon vegetables when more nourishing diet is unattainable. It leads a very solitary life, amidst the sedges of extensive marshes and fens, concealed beneath the flags and reeds, and continuing whole days about the spot, seeming to look for safety in retirement and inaction. Its principal food, during summer, consists of fish, frogs, and insects; but in the autumn it repairs to the woods in pursuit of mice, which it seizes dexterously, and swallows whole.

A female bittern that was killed during a severe frost, had in her stomach several water lizards, and the remains of frogs, which were supposed to be taken out of the mud under the shallow water in the swamp where the bird was shot. Latham mentions having seen two middle-sized trouts, perfectly whole, taken from the stomach of a bittern.

This bird is easily shot, as it flies heavily; and, though generally very timid, will, nevertheless, when wounded, make a desperate resistance. Mr. Markwick once shot a bittern, in frosty weather, that fell upon the ice, just strong enough to support the dogs that eagerly attacked it; but being only slightly wounded, it defended itself so fiercely with its bill and claws that the dogs were unable to subdue it, and it was ultimately killed by another shot.—When wounded, it has been known to strike its bill through the boot of the sportsman, and even to hurt his leg. The bittern breeds in the fens, making its nest in April, which is principally composed of rushes. The female lays from four to six eggs, of a pale greenish ash colour; the young are produced in twenty-five days, and have an ugly appearance, arising from the extreme height of the neck and legs; they continue in the nest about twenty days, during which time the old ones feed them with uncommon assiduity. Hawks, which plunder the nests of most water-fowls, will seldom venture to attack that of the bittern. The most remarkable part of the history of this bird, however, is that hollow booming noise which distinguishes it from every other part of the feathered creation; and on this account it has been regarded with a sort of superstitious detestation by the vulgar. Of all sounds, perhaps, there is not one more dismally hollow than the booming of the bittern.

It is impossible for words to give those who have not heard this call an adequate idea of its solemnity: it resembles, in some degree, the interrupted bellowing of a bull, but hollower, and, perhaps, louder, and may be heard at the distance of a mile, as if issuing from some formidable being that resided at the bottom of the water. These bellowings, or boomings, are produced by the males, and are chiefly heard morning and evening, during the months of February and March, which is unquestionably the season of courtship. Many of the common people are of opinion, that to produce this booming, the bittern thrusts his bill into a reed, which serves as a pipe for swelling the note above its natural pitch, while others imagine that the bird puts its head under water, and, by blowing violently, produces its boomings. These boomings are given six or eight times in succession, then discontinued for a short space, when they again follow in similar succession.—The above notice of the manner in which

BIRDS. *Plate I.*

BITTERN, *p.* 58.

BUSTARD, *p.* 99.

this bird produces its hollow boomings, is in all probability quite erroneous, as its anatomy seems to testify: the windpipe differs from all other animals, and is apparently calculated to produce the sound for which the bittern is so remarkable; the lower part of it, dividing into the lungs, is supplied with a thin loose membrane, that can be filled with a large body of air, and exploded at pleasure: thus these boomings are produced, which, though so awful to the human ear, are the calls of courtship, or the expressions of connubial felicity. Although the bittern is in general a sluggish heavy flying bird, yet in autumn this character is greatly changed, as it is then seen rising in a spiral ascent, till it is quite lost from the view, uttering, at the same time, a singular noise very different from its former boomings. In some places it is distinguished by the name of the bitter bump, in others, by that of the mire drum.

BITS are of two kinds, the one operating on the horse's lip, by compressing it against that part of the horse's jaw, called the bars, which are the gums between the the tush and grinders; these go under the denomination of snaffles and bridoons.

The other, compressing the bars and beard by the assistance of the curb and power of a lever, are commonly called bits; but, as the ingenuity of man has, from time to time, varied the construction, fashion, and sometimes properties, very injudiciously, they have received names and appellations which have been applied sometimes to one bit, and then to another, that a bit-maker now cannot be certain of of what bit you mean, except enquired for by its distinguishing name, viz. the Cannon bit, the Pelham bit, the Pembroke bit, the Weymouth bit, the Hard and Sharp, the Portsmouth, the Chifney, &c. &c. Leaving, therefore, any enquiries about names, I shall proceed to notice those only which I conceive useful and consistent, and omit all the petty whims and inventions, which are innumerable, and originated some from the bit-makers to promote trade, (since many will have whatever is new) and others from conceited horsemen, who require a bit to make up for the deficiency of their hands.

Though I admit but of two kinds of bits, yet their construction may give mildness or severity in their operation. I shall therefore begin with the mildest bit, which is sometimes called a colt's bit, or mouth-ing bit: the part that compresses the lip against the bars is made large and smooth,

for the larger the mouth-piece of the bit the milder it operates, as you may judge by only lifting a heavy weight, first with a thin ring and then with a thick one. This bit is rendered still milder by the centre of the mouth-piece being united by a ring, which renders the pressure less severe. There is usually to a colt's bit, a flat triangular piece of iron suspended to the ring, and three or four drops suspending from that; these are intended to stimulate the tongue to move, which promotes slaver; by which means, the mouth is kept cool and refreshed; for when the mouth is dry and hot, it becomes numbed and insensible. The cheeks to this bit, and all snaffles, should be six inches long, and the eye to fix the head-stall and reins sufficiently large that stout reins may freely traverse.

I shall next notice, the common plain snaffle; the mouth-piece of which is generally about the thickness of one's finger; they are so well known that they need no description. If you take the mouth-piece in your hand, and pull by the reins with the other, you will comprehend immediately their operation; and, if you try the colt's bit in like manner, you will perceive how mild that is rendered by the ring uniting the mouth-piece. This snaffle may be used after the colt's bit, and is proper to ride with by those who prefer snaffles; some variation in the powers of this bit will be occasioned by the length and thinness of the mouth-piece, which renders it sharper—thick and short will be mild. To render the snaffle more severe, a twisted one will be found to answer; the deeper they are indented, consequently the more acute will be the operation. These, therefore, are proper for horses that have hard callous lips; some are more callous and insensible by nature than others, but many are rendered so by heavy dead hands.

Horses that have their shoulders well back, their crest rising, and neck arched, so that the nose, when they are united, does not exceed forty-five degrees from a perpendicular to their forehead, will ever ride pleasant and manageable even in hunting with the snaffle, and it is the preferable bridle to ride such horses with.

The bridoon is a snaffle without the cheek; this is only used with another bit, and the cheeks would interfere and be more incumbrance than use.

The mouth-piece of the snaffle must be placed in the mouth, not to gag or wrinkle the corners of the mouth, and it is of no

consequence how low, so that the horse cannot get it over his tush, for the operation of the reins brings the snaffle to the place it is to act.

I now come to notice, what goes under the general appellation of the bit. This, also, is universally known to those conversant with horses, but not so universally considered. Its parts are the mouth-piece-curb, curb-hook, cheeks, and branches. The mouth-piece is that part received within the mouth, the length of which, should be agreeable to the size of the horse, usually about five inches, and round; the ends of which should rest on the bars, and the middle form a cavity for the tongue to lie easy and undisturbed.

The cheeks are the upper part of the lever, above the mouth-piece, on each side the jaw; the branches are the lower part, and are straight or crooked agreeable to fancy: the power of the bit chiefly depends on the length of these, and I have seen some only three inches in length, others twelve, both of which are inconsistent extremes. Each end of the mouth-piece is fixed into the cheek; which should be at the distance of two inches and a half from the top, and soldered or rivetted to be as firm as one piece. The curb is a chain, so constructed as to lie smooth and flat under the jaw: one end of the curb is clenched fast to the upper part of the off cheek of the bit, and a hook is clinched to the near cheek, to link the curb-chain to. Rings at the extreme ends of the branch, for the reins to be sewed to, are preferable to loops.

The power of the bit increases in the proportion as the length of branch exceeds the distance the curb is fixed from the mouth-piece; so, that if the curb is fixed two inches and a half above the mouth-piece, and the reins operating from the lower part of the branch five inches below the mouth-piece, for every ounce you pull on the rein, you press two with the curb on the jaw, and three with the mouth-piece, on the bars.

The length of branch may be varied according to the powers you want in the bit. Gentlemen, who have heavy hands, and light-mouthed horses, must have their branches shorter by an inch; and those who cannot govern their horses, but by the extreme powers of the bit, must lengthen the branch an inch.

The cheeks should have round loops for the head-stall, rather than square ones, because the leather sits smoother and

pleasanter, as the bit operates. All corners or edges that can possibly rub the horse's cheek, or chafe the hair off, should be avoided. The cavity in the mouth-piece for the tongue, I by no means would recommend to be a very high portmouth. Those high portmouths were invented to force the jaws open, and render the horse very uncomfortable, but that is no consideration to the man that cannot hold his horse by other means.

The form of the branch may be after what fashion you please, so that you retain the power you require; varieties of curves and figures have been invented, some only for fashion, others to prevent the horse lodging the branch on his gatherers. This is what many horses will do, without having any mischievous intent. But as the bit does not properly operate, it should be prevented; which is easily done by a small chin-strap, if properly placed and buckled; but many are so constructed as to be of no use. Should a person be unprovided with a chin-strap, and the horse addicted to get the branch on his teeth, you can dislodge it by slacking the hand, and shaking the reins; the harder you pull, the firmer it holds.

With the bit, a bridoon is usually mounted; this leads me to a few remarks on mounting a bridle.

Here I shall avoid interference with fashion, and only note convenience. There are two methods of mounting a bit and bridoon bridle: the first, and the most usual, is adapted for riding the extended paces, and hunting—this has the longer and stouter rein fixed to the bridoon, and the shorter one to the bit.

The other method is calculated to ride in the united paces, consequently is used in the manege, the army, and for ladies' bridles, &c. It is usual to fix the bridoon to a separate head-stall from the bit; this has its inconvenience, for we use but one rein of the bridoon to support the position, and if the horse is stiff, or reluctantly bends, the bridoon, having no cheeks, will draw through the mouth. But the more old-fashioned way was to fix the bridoon to the same head-stall, having it sufficiently wide to divide at the ends, one to receive the bit, and the other the bridoon, and by this method the bridoon, cannot be drawn through. If the former method is adopted, you must have a nose-band, with loops in the head-stall of the bridoon for it to pass through, and that may prevent it. The shorter and lighter rein is to be fixed

to the bridoon, the stouter and longer rein to the bit. This rein is usually joined in the middle, by putting end to end, with a piece of leather between to thicken the substance, that a slider on the rein may not pass over. This method is readily to ascertain the middle, to adjust the reins even.

But there is an oversight committed in this, for the near or left rein should be at least half an inch longer than the other, by reason it has to pass under the little finger, and on the outside of the left rein over the forefinger, which will make a difference from half to three quarters of an inch.

To guard against what is termed the horse running through his bridle, that is, the curb being too slack, so that the branch loses all its power before the curb takes any effect, they run into the opposite extreme, when the branch loses great part of its power, and the horse rendered uncomfortable by the gagging of the bit. Uniformity is much regarded in the army, since the whole regiment has an uniform bit of the same powers and dimensions in every part, but the horses may vary widely, some carrying their heads high, others low, some poking their nose out, and others bridled to the chest—these circumstances require a trifling difference in the adjustment of the curb. It therefore requires some knowledge of the horse, to know precisely how to adjust his bridle.

If we examine in what situation the bit operates with the greatest power, it will be found, when the direction of the reins forms a right angle with the branch of the bit; and the more acute or obtuse angle it makes, the more power we lose.

In adjusting the bridle on the horse, the head-stall must be of that length that admits the mouth-piece of the bit to rest on the bars, a little above the tush; the bridoon a little shorter, but not so high as to wrinkle the corner of the mouth, the throat-lash buckled rather loose, to admit the horse when going to bridle his head. The mane is usually cut close where the head stall comes, and the finger should clear any part of the mane, or fore-top, that may interfere with it. The fore-top when combed smooth, may be put over or under the front; the curb is the last thing adjusted, and though a trifling variation may be proper, according to the manner the horse carries his head, I shall set down that criterion which suits the generality of horses.

The curb-chain, observe, is to pass under

the bridoon; therefore, put your right hand under the bridoon reins, to take hold of the curb-chain; and, with the left, put two fingers within the cheek of the bit, and with your thumb take hold of the curb hook. The end links of the curb-chain being in your right hand, turn the chain to the right, or as you would turn a screw, till every link lies smooth and flat, as though it was a strap; and then, without losing a half-turn, put that link on the hook, as appears to be most appropriate, i. e. neither tight nor slack, and examine how the branch operates. If the branch has liberty to move 45 degrees, and no more, it is the criterion I judge most proper; but a few degrees, more or less, is not to be regarded. Nevertheless, if one link of the chain confines it to 35 degrees, and putting it one link looser gives it liberty to 55 degrees, the manner your horse carries his head must determine which of the links is most proper. If the horse naturally carries his nose high, let the branch have 55 degrees; if he brings his nose in, 35 will be best.

If there is a chain-strap, the strap must be placed so high on the branch, that when passed through the ring in the curb-chain, it must be buckled to that tightness that precludes the possibility of the horse lodging the branch on his teeth. Unnecessary tightness should be avoided, as it renders the bit less comfortable to the horse.

Though I object to the curb being too tight, I must caution you against having it too slack; for though the horse could not run through his bridle if the branch went 75 degrees back, if the horse carried his nose high, yet if he bridled his head in, your reins would form such an obtuse angle with the branch, that you would lose the power of the branch: therefore, adhering as near as you can to the medium of 45 degrees will be found best.

**BLACK ACT.** This was enacted and so called, from the circumstance of the most unprecedented depredations committed in Essex, by persons in disguise, with their faces blacked and disfigured. It runs thus:—By this statute it is enacted, that persons hunting armed and disguised, and killing or stealing deer, or robbing warrens, or stealing fish out of any river, &c. or any person unlawfully hunting in his majesty's forests, or breaking down the head of any fish-pond, or killing of cattle, or cutting down trees, or setting fire to houses, barn, or wood, or shooting at any person, or sending letters,

either anonymous, or signed with a fictitious name, demanding money, &c. or rescuing such offenders, are guilty of felony, without benefit of clergy.—This is commonly called the Waltham Black Act, and was made perpetual by 31 George II. c. 42.

**BLACK-AND-ALL-BLACK**, also called **OTHELLO**, was bred by Lord Portmore in 1743; he was got by Crab out of Miss Slamerkin, by young 'True Blue; grandam by Lord Oxford's dun Arabian, out of a D'Arcy black-legged royal mare. His performances denote him to have been one of the best horses of his time: in 1748, he won 50 guineas at Lewes, and £50 at Stockbridge; in 1749, the king's plates at Salisbury, Canterbury, Lewes, and Newmarket; in 1750, at the Curragh of Kildare, he won the 100 guineas given by the Sporting Society, and 50 guineas and the king's plate at Maryborough; in 1751, he beat Lord March's Bajazet, on the Curragh, a match, four miles, 1000 guineas; in 1752, he won the sportsmen's subscription purse of 50 guineas, and the king's plate, at the Curragh, beating Lord Antrim's Gustavus. Othello returned to England, and covered in Cambridgeshire at five guineas.

**BLACK COCK,**  
**BLACK GAME,**  
**BLACK GROUSE.** } See **GROUSE**.

**BLACK-LEG.** This well-understood expression was long since given by the superior classes of the sporting world, to a fraternity of unprincipled sharpers, who are, perhaps, without exception, the most designing and abandoned set of thieves and harpies that ever disgraced civilized society. They are a community existing by, and subsisting upon, the most villainous plans of deceptive depredation: their various modes of attacking and preying upon the credulity of the inexperienced and unsuspecting part of the public, are beyond conception or belief: their number is incredible, and their stratagems exceed description. Destitute not only of character, but of every honourable and praiseworthy feeling, their minds are destined solely for the purposes of determined devastation upon the property of those unthinkingly seduced or betrayed into their company; upon whose credulity and indiscretion they are supported in a continued scene of the most luxurious and fashionable dissipation. As members have no great power of exerting themselves with much success individually, the *firm* (if a most infamous combination can be so

termed) are adequate to almost every desperate undertaking, from *pricking in the belt, hustling in the hat, or slipping a card*, to determined highway robbery. They are sole proprietors of the different gaming-tables, public and private, as well in the metropolis, as the hazard, roulette, &c. at all the races of eminence in the kingdom. They are invariably present at every fashionable receptacle for sport: the tennis-court, the billiard-room, the cock-pit, have all to boast a number of these miscreants in quest of plunder; and even the commonest coffee-house is a spot where *modest merit*, in the form of a lounging emissary, frequently obtrudes, in the anxious hope of picking up some opulent juvenile, that he may afterwards enjoy the pleasure of introducing him, in the most liberal and friendly way, to another member of the fraternity, as a very proper object, or *pigeon*, well worth plucking for the benefit of the family.

**BLADDER, INFLAMMATION OF THE.** This is a disease which does not often occur to horses, and, when it does, most commonly depends upon the too free use of strong diuretics. During an attack of this disease, the horse is almost constantly endeavouring to stale, only voiding a few drops at a time. The frequent staling is caused, not by the bladder being full of urine, but by the extreme irritability of the bladder, in consequence of its inflamed state. Bleeding is the first remedy to be employed; and if the pulse is very quick, the inner surface of the eye-lid red, and the breathing disturbed, you should take away not less than five or six quarts, provided the horse does not faint before this quantity is lost. The bowels should be opened, and any hard excrement there may be in the lower gut removed by means of clysters. The horse should drink plenty of the infusion of linseed; and if the symptoms of the disease still continue, he should have an anodyne clyster, and a ball, once every six hours, composed of camphor, one drachm, opium, half-a-drachm, made into a ball with linseed meal and treacle. If the disease still continues, bleed again, for it will be the only chance of saving the animal's life that remains. Horses are often affected with irritability of the bladder, without pain; this causes them to stale much oftener than usual; but the quantity of urine voided is not so small as in the above-mentioned disease; they likewise are free from fever, and feed well. This state of the bladder is too frequently brought on by the pernicious custom of

giving diuretics on every trivial occasion: when a horse is troubled with this irritability of the bladder, give him the ball we have mentioned above, with the addition of five or six drachms of nitre; letting him drink freely of the infusion of linseed. An accumulation of urine is sometimes produced by the folly of those people who ride their horses a long way, without allowing them time to stale, the ball mentioned above is the best remedy.

BLEAK are handsome fish, but do not grow to a large size, seldom exceeding two ounces in weight, and not much valued for their flavour: they are a lively sportive fish, and easily taken with a small fly at the top of the water, and with paste or gentles at mid-water, or at the bottom. Angle for them with a light rod, single hair line, small quill float, and No. 12 or 13 hook. They will bite all day from April till October, affording the young angler sport and practice; these may be caught in all parts of the New River, from Sadler's Wells to Ware. I have found the greatest sport, in angling for bleak, to bait with one gentle on a No. 12 or 13 hook, and fish about a foot deep, using a hair line, very small quill float, and keep continually throwing in half-a-dozen gentles for ground bait, or a little chewed bread. Strike the moment you perceive a bite.

BLEEDING, is the essential remedy in all the diseases of the horse, depending on inflammation, and in these cases the earlier and more freely it is employed, the more beneficial will it be in its effects. The veins which are the best to bleed from, are the jugular or neck veins, and the instrument most generally used is a fleam; however, of late years, the lancet has been used for this purpose, and in skilful hands it is much the best instrument. Some operators tie a cord round the neck, in order to raise the vein, that they may be enabled to bleed with more certainty; this is unnecessary, and may be productive of much mischief, particularly in cases where the brain is already loaded with blood, as in mad staggers.—Always bleed by measure; indeed, it would be of great use to have a vessel marked on the inside, in the same way that the basins used by surgeons are: the quantity of blood taken away, may then be readily seen. In highly inflammatory disorders, making a large orifice, so that the blood may flow in a large stream, will be found much more efficacious, than the same quantity of blood taken away slowly, from

a small opening. The blood taken away should be always set aside for examination; and, if it has a buff-coloured jelly on its surface, it denotes an inflammatory state of the body; if it remains firm and not easily broken, the operation may be repeated, if the disease has not been subdued by the first bleeding. In some cases the blood, after coagulating, will have a great deal of this buff-coloured jelly on it, but at the same time it will be thin and watery, this shews great weakness and a tendency to dropsy, and the like diseases. Green food in a loose box, or a warm well-sheltered field, is the best remedy you can employ. The great nerve of the neck has been injured, by bleeding too low down in the neck. The proper situation for bleeding is about four inches from the part where the vein divides into two branches. Topical or local bleeding is often recommended; the only part at which it is really useful is in the foot; or, bleeding in the toe, as it is commonly called; in strains about the foot and pastern, bleeding in the toe is likely to be found much more useful than bleeding from the neck. The manner of bleeding in the toe is as follows:—Having taken off the shoe, and pared away the hard and exterior parts of the sole or bottom of the foot, make a transverse incision, about an inch and a half in length, with a drawing knife, in the sole near the toe, of a sufficient depth to open some of the blood vessels, which about that part are very numerous.

Bleeding from the temporal artery has been thought more effectual than bleeding from the neck, in staggers. Bleeding in the angular or eye vein, is sometimes practised in inflammations of the eye, but it does little if any good.

Bleeding in the plate vein, used by some farriers, in injuries of the shoulder, is in no respect preferable to bleeding in the neck, nor is there any advantage in bleeding from the thigh or kidney vein, as some do when the kidneys are supposed to be affected.

Bleeding in the roof of the mouth, considered by many as a useful remedy in certain disorders, is certainly of no use, there is no circumstance, whatever it may be, which can render this operation necessary, and such accidents have happened, as a horse bleeding to death, from the artery of the palate having been opened instead of the vein.

After bleeding, inflammation of the orifice may take place, which may extend

to the vein, and from it to the heart; it, however, most commonly spreads upwards, and generally terminates in the obliteration of the vein. This is often in consequence of pinning up the vein after bleeding, in a careless manner, or the wound may be poisoned by the fingers of the operator, that have been just before employed about the nose of a glandered horse, or the heels of one suffering with the grease, &c. It is the custom of some, to bleed their horses every spring, and may be of advantage in some particular cases, where it is indicated by their rubbing themselves, having an unusual redness of the eyes, dulness, languid appetite, and unwillingness to work. But such occasions for bleeding would not often happen, were feeding, exercise, and grooming, properly attended to. When a horse has been bruised from a fall, or otherwise, it is proper to bleed freely, particularly when he has had a blow on the eye, which sometimes happens. Copious bleeding, when a horse has been over-ridden, is of great use.

**BLEMISHES**, are disfigurations of the horse, without any impediment to sight or action; they are often called eye-sores.—Blemishes are of various kinds, some not easily seen, and some very conspicuous, as broken knees, splents, warts, thrushes, sandcracks, the marks where a horse has formerly been severely blistered, the marks made by firing, &c. &c. A horse may be very much blemished without being unsound.

**BLINDERS**. See **HARNESS**.

**BLINDNESS** is more frequently met with in the horse than any other animal. Not that the eyes of the horse are peculiarly liable to disease; but from the violent exertions to which he is urged, and to the improper manner in which he is fed and kept, must this be attributed.—How often do we see horses taken out of a hot dark stable, where they have been standing, perhaps, two or three days without exercise, and ridden immoderately, without considering, that from standing for such a length of time, the bowels will not only be filled with excrement, but the blood vessels with blood. It cannot then be wondered at, that an organ so delicate as the eye should suffer. Colts got by stallions that have diseased eyes, are much more liable to blindness than others.—Many horses lose their eyes from extreme exertion in drawing or racing. Prevention is the object to which we should look, for when once disease of the eye has taken

place, it is very seldom perfectly and permanently cured.

**BLINKERS**. See **HARNESS**.

**BLISTERING**. This operation is performed on horses by various substances, the principal of which is the Spanish fly. They are generally employed in blood and bone spavins, curbs, strains, &c. Blistering is very frequently much too soon resorted to as a remedy, often before the inflammation caused by the original injury has sufficiently subsided: this is “adding fuel to fire;” and from this injudicious plan of treatment, enlargements of the part are often found, which are never got rid of. Corrosive sublimate, oil of organum, oil of turpentine, &c. are also occasionally employed as blisters.

Blisters may be used in the form of either ointment, liniment, or tincture; this last is called the liquid blister, and is preferred by some practitioners. However, the ointment is the most generally used. Before a blister is applied, the hair must be cut off from the part as closely as possible. The blistering ointment or fluid is then to be well rubbed on to the part, with the hand, for the space of ten minutes or longer; after this, if the ointment is used, some of it may be spread on the part and left there. The horse's head should always be so secured as to prevent him from biting or rubbing the part; which he will do if he can for several days after. About the third day after blistering, he may be turned into a loose box, with a cradle about his neck. In about a week the part should be dressed with some mild application, as olive oil, or tar and oil mixed together—this will keep off the flies. In blistering the legs, great care must be taken to avoid the part of the heel under the fetlock joint, and it is a good plan to rub a little hog's lard on it, in order to defend it from any of the blistering material that may run down the leg. All the litter must be removed from the stall, when the legs are blistered.

#### LIQUID BLISTER.

Spanish flies in powder	1 oz.
Water of pure ammonia	2 oz.
Spirits of wine	half a pint.

Shake up these ingredients frequently in the bottle for a week; then pour off the clear fluid, for use.

#### BLISTERING OINTMENT.

Yellow wax	1 oz.
Hog's lard	4 oz.
Oil of turpentine	1 oz.
Spanish flies finely powdered	6 drs.

Melt the wax and hog's lard over a slow

fire, then add the oil of turpentine and cantharides, constantly stirring them until the mixture stiffens in cooling.

## BLISTERING LINIMENT.

Olive oil	2 oz.
Water of pure ammonia	2 drs.
Oil of turpentine	3 drs.
Spanish flies in powder	2 drs.
Mix them well together	

Corrosive sublimate should never enter into the composition of blisters, as it is very apt to cause troublesome sloughing sores; neither, in our opinion, should the sulphuric acid, though it is used by many.

BLOOD is the fluid which supports animal life, and when taken from the animal beyond a certain proportion, causes instant death. It is that fluid which circulates in the cavities of the heart, arteries, and veins. In the larger animals it is of a red colour, but in some it is colourless. Whilst circulating, and immediately after being drawn from an artery or vein, it appears one uniform mass; but soon after being taken from the vessel, it loses

its uniform consistence, and resolves itself into two parts; serum and crassamentum. In inflammation the blood coagulates slowly, therefore, time is given for the red particles of the blood to sink below the rest, and this is what is called the "buffy coat," denoting inflammation. The blood taken from an artery is of a much more florid or red colour than that taken from a vein. The blood is the material used in the formation of new parts, and in the restoration of those injured by accident or disease, and from it the various secretions are formed, as bile, urine, semen, &c.

The tubes through which the blood is propelled from the heart, are called *arteries*; these *anastomose* or unite with other tubes called veins, through which the blood is sent back again to the heart.—When an artery is wounded, the blood, which is externally red, flows in successive jets or gushes; whereas, when a vein is wounded, the blood, which is dark, flows in one continued stream.

**BLOOD HOUND.** Nothing can be more ridiculous than the absurd notions which have been propagated respecting the dog passing under the denomination of *blood hound*; and, even those who have published their thoughts on the subject, (if we except the author of the "Shooter's Companion,") have entertained the crudest and most ill-defined ideas on the subject, as their remarks so evidently shew.

The dog passing under this name, was called in Scotland the *sleuth hound*, and in England the *talbot*, and he was, in all probability, introduced into these islands by William the Conqueror. At all events, the dog under consideration was evidently the original stock whence have sprung all those ramifications, which, under the name of southern hounds, northern hounds, fox hounds, stag hounds, beagles, &c. are to be met with in various parts of Great Britain.—The old talbot or blood hound, as far as we are able to form an opinion, was about two feet four, or two feet five, inches high, of substantial, strong, compact, and muscular form; the face wide, and the head altogether large; nostrils, wide and expansive; ears, very large, long, soft, and pendulous; the countenance solemn and majestic; the tail tolerably long, with an erective curve, particularly when in pursuit; with a voice awfully loud, deep, and sonorous.

If we are to believe what has been written on this highly interesting subject, one distinguishing trait of purity in the breed consisted in the colour, which was a reddish tan, gradually darkening to the upper part, with a mixture of black upon the back, becoming some shades lighter in reaching the lower parts and extremities: some few, it is said, had a little white in the face, but this was by no means common with the majority of the breed. The writer saw several specimens about forty years ago, and from these, as well as from the observations he has been able to make upon hounds in general since

## B L O O D H O U N D

that period, he has reason to believe, that though in the talbot or blood hound a variety of colours might be found, as in the deep-flewed southern hounds of the present day, yet that the prevailing colour was the dark or black just mentioned, with, in all probability, the tanned marks over the eyes, so often seen in the modern hounds, as well as in smooth-haired black terriers. In fact, the best idea may be formed of the talbot from the contemplation of the deep-flewed southern hound, which may perhaps be justly regarded as a smaller kind of talbot.

The great and distinguishing peculiarity of the blood hound or talbot, was his infallibility in tracing to its final resort, any animal that had strayed away, or had been stolen, and also in tracing the thief himself. We are told, that the old method of teaching or training the blood hound was, in the first place, to encourage him to follow, or rather, trace, a wounded deer, in company with an old staunch hound; and at the termination of the chase he was regaled with some of the venison, as a reward for his labour, and an excitement to future service. When perfect in these introductory lessons, the shoes of a man (possessing great speed, strength, and perseverance,) were rubbed with the blood of a deer; he then, taking a remote circuit of a mile or two, occasionally renewing the blood to the shoes, as the effluvium (scent) became less effectual or more obliterated.—These inculcations were continued, and the circuit more enlarged, lengthened, and extended, till, having afforded satisfactory proof, his last experimental lessons were to hunt the dry foot of a man upon whom he had been instructively laid; and by these means the dog was rendered capable of following that pursuit for which he was ultimately intended. This, however, was rather a round about method of teaching the dog his business. To be more explicit—if perfection be desirable in hunting, or the desideratum at which we aim, a hound intended for any particular chase, should be first stooped at, and encouraged to hunt, that same scent, and that alone; and by this means he will acquire a proficiency which is not otherwise attainable. It is more than probable, that the name of blood hound was given to the dog under consideration from the circumstance of receiving his preliminary lessons with the blood of deer, or from his ulterior employment of pursuing thieves. But, if we consider the subject philosophically, we shall easily perceive that the word *blood* has no particular application in this case, more than the hunting of any other kind of hound or dog. Blood may be justly considered as the basis or fountain of scent; as the latter is neither more nor less than minute particles of the former, which, in the process of nature, or animal economy, are expressed or driven from the body, and become colourless in the operation. Therefore, as all dogs which pursue the chase by means of smell, are guided by the scent, so all may, consequently, by the same rule, be denominated blood hounds. However, the talbot evinced a sagacity, in this respect, so superior to any other kind of dog, that accounts which partake of the marvellous have been frequently reported of him: the fact is, the talbot was gifted with superior olfactory organs, or powers of

## B L O O D H O U N D

smell; and the ignorant, therefore, were willing to give him credit for supernatural cunning; or, in other words, worked what they could not comprehend into a sort of semi-miracle; though, in these more enlightened days, the cause is known, and therefore wonder in a great measure ceases.

The talbot, as already observed, has a very large head; perhaps, by comparison, larger than that of any other kind of dog; and as, on this account, he is more abundantly supplied with olfactory organs, he, of course, possesses a better nose, or more exquisite smell, and is thus enabled to carry on a scent where an animal with inferior powers would not be able to touch it. It is a very well known fact, that the sense of smell varies very much in dogs; or, to speak as a sportsman, some of them possess better noses than others. In dogs with broad heads, the *os æthmoides*, or sieve bone, is much larger than in narrow headed dogs; the *lamine cribose*, or the sieve itself, is therefore, more capacious, and contains more openings; so that the olfactory nerves which pass through it are divided more minutely, and thus that exquisite acuteness of smell is produced, which must always be found to obtain in dogs with large broad heads; and hence we easily perceive why the talbot, in this respect, stood pre-eminently conspicuous: this excellence or superiority of the olfactory organs is further assisted by the largeness and flexibility of the lips and skin about the nose, which thus admit of much greater extension of the olfactory nerves, and render them more susceptible of external impressions. The olfactory nerves resemble a bunch of small white cords, one end of which is connected with the brain, while the other, descending the head, spreads into numerous ramifications, reaching to the edges of the lips, as well as to the extremity of the nose.

Hence the inferiority of the greyhound's sense of smell will be easily perceived: his head is narrow, while his lips are thin and compressed; and, in consequence of this inflexibility, and the contracted structure of the head, that breadth and extension of nerve are inadmissible; and, to make up, as it might seem, for this defect, nature has endowed him with a celerity which is not to be met with in any other species of the dog.

All dogs, therefore, with broad heads, must possess superior organs of smell; but, it does not appear that a narrow or sharp nose presents any obstacle, as the main bulk of the olfactory organs are situated in the head; but yet, it would appear evident, that a very long nose, like that of the greyhound, must always be detrimental, since the impression of scent, externally caught, must have further to travel to the brain. The wolf and the fox have both sharp noses, but their heads are remarkably broad and capacious: their olfactory organs are unquestionably of the first order. Experience, in fact, fully verifies these conjectures. The dogs most remarkable for exquisite sense of smell, are equally distinguished for broad heads; and the gradations are easily to be traced:—the talbot, the original of all our modern hounds, exhibits the outward characteristics of superior olfactory nerves, in a very obvious and striking manner: by

## B L O O D H O U N D

crossing the talbot with something of the greyhound breed, the stag hound was produced: the speed of the talbot was thus increased; but, as the head became more compressed, the sense of smell suffered accordingly. The fox hound is a still farther remove, and his olfactory organs are inferior to the stag hound; and, the reason, in fact, why well bred stag hounds distinguish the blown or hunted deer from the herd, is entirely owing to their proximity to the talbot; while the fox hound, by being further removed, is unable to distinguish the hunted or blown fox, when another happens to come in the way during the chase.

Admitting, therefore, that the talbot is superior to any dog on the score of scent, we shall find that he is equally remarkable for the depth and power of his voice; while his ears are also conspicuously large: it would seem to result, therefore, that in proportion to the size of the head, the quality of the nose may be, in a great degree, ascertained; and, it will be found also, that those dogs which are remarkable for the acuteness of their olfactory organs, have large ears and deep powerful voices. Of the truth of these observations, a very little consideration must convince every sportsman: he will easily perceive a vast variety in the hound tribe, and he will perceive also, that in proportion as these varieties are removed from the talbot, will be the goodness of the nose, the size of the head and ears, and the depth of the voice.

The Spanish pointer is remarkable for a broad capacious head, as well as for large pendent ears; and his exquisite sense of smell is too well known to need any comment in this place: and those setters distinguished for their superior noses, will be found to possess a very considerable expansion of the head, though their noses may taper more than the pointer. Thus, at first glance, a bull dog will be supposed to excel in this respect; but, on examination, it will be found, that his head is rather chubby than broad, while the skin about the mouth is comparatively inflexible and compressed, his under jaw projected, and his nostrils thrown so far back as to prevent that immediate contact with external objects, which is seen to obtain in the dogs before mentioned; yet, notwithstanding all these objections, the bull dog's sense of smell is of the superior order, which arises, no doubt, from the capaciousness of his head.

Blood hounds were formerly used in certain districts lying between England and Scotland, which were infested by robbers and murderers; a tax was laid on the inhabitants for maintaining them, and there was a law in Scotland, that, whoever denied entrance to one of these dogs, in pursuit of stolen goods, should be deemed an accessory.

*Hot-trod*, was the pursuit of offenders, called moss troopers, by blood hounds, or *slough dogs*, as they were named, from exploring the sloughs, mosses, and bogs, which were passable only by those acquainted with the various and intricate by-paths and turnings.— These dogs were in use so lately as the reign of James I. From a warrant then issued, it appears that *nine* of them were ordered to be provided and kept at the charge of the different inhabitants. The

## B L O O D   H O U N D

lord warden of the Marches, in old times, was to have a council, chosen of discreet borderers, who were to inquire into murder, maiming, burning of houses, corn, &c. rapine and theft, deadly feud, threatening of life in revenge, cutting down trees, destroying corn, depasturing cattle, hunting beyond the established limits, &c. A thief might be pursued into the opposite realm within six days, and the chase carried on, as the term is, in *hot-trod*, with hounds and horn, with hue and cry; in which pursuits, receivers and rescuers of the fugitive were equally punishable with the principal. The regulation of the borders, by distinct and effective laws, seems to have commenced in the reign of Edward I. about the time when he aspired to the sovereignty of Scotland. Robert de Clifford, lord and hereditary sheriff of Westmoreland, was the first lord warden of the Marches, to which situation he was appointed in the year 1296.

There is much reason to believe that the noble talbot, or old English blood hound, is nearly, if not altogether, extinct. There is something of the kind still in use amongst park-keepers, and game-keepers also; the former use them for selecting a wounded deer from the herd, and seizing it; and the latter, as a sort of companion in their nightly perambulations, and for the purpose of pursuing poachers. The writer saw one of these dogs some years ago, which had been obtained from a gamekeeper in Oxfordshire, and which was represented as a thorough-bred old English blood-hound; but this was not the case: it was a fine-looking animal, about three parts talbot or blood-hound. In all probability the true breed might soon be restored, should any sportsman think their restoration desirable.

The talbot was, perhaps, the noblest variety of the dog tribe: while he possessed that exquisite sense of smell that enabled him to pursue a thief through all possible mazes, he had also, at the same time, courage and strength sufficient to seize and hold him till other assistance came up. While the then barbarous, inveterate, and unrelenting clans of the north, under petty chiefs, were perpetually engaged in civil broils, the vanquished, who fled from the sanguinary conflict, were often hunted from cave to cave by a dog of this description, and slaughtered in cold blood. Deer-stealing, not much more than a century ago, was so common, that foresters and keepers were under the necessity of keeping up an eternal watching and nocturnal warfare; the hounds under consideration were constantly trained to the practice, and so closely adhered to the scent they were once well laid on, that, even after a long and tedious pursuit, detection was considered certain and inevitable. An offending criminal was formerly considered as not only positively taken, but half convicted, the very moment a blood-hound was laid on his track.

The Spaniards, in the West Indies and South America, are in possession of a very large and fierce animal, which they denominate a blood hound, and with which they hunt the runaway negros; yet this animal differs very much indeed from the old English blood hound. He is about the same height as the talbot, with small erect ears, (which the Spaniards generally crop) the nose more pointed, and the

## B L O O D   H O U N D

hair and skin hard: his countenance is forbidding, ill-natured, and ferocious; he is not so heavy as the English blood hound, but extremely muscular, and very active. Indeed, to form an opinion from appearances and disposition, it might seem that the blood-hound of the West Indies had been produced by crossing the boar-dog of Germany with something of the rough greyhound kind.

At no very remote period, the unfortunate negros in the Spanish settlements, in the western hemisphere, were frequently torn to pieces by these blood hounds; and regular regiments of them still exist in Cuba, and other places, under the title of chasseurs. One man has the charge of two dogs; and Don Manuel de Sejas commanded a party of these men and dogs, which were procured from Cuba for the purpose of hunting the refractory Maroons in Jamaica. A tolerable idea may be formed of the character of these dogs, from a review which took place immediately after their arrival. General Walpole, being anxious to review these chasseurs, left head quarters the morning after they were landed, accompanied by Colonel Skinner, and arrived in a post-chaise at Seven Rivers. Notice of his approach having been given, the chasseurs were taken to a distance from the house, in order to be advanced when the general arrived. The Spaniards were drawn out in a line at the end of a gentle declivity, and consisted of upwards of forty men, with their dogs in front unmuzzled, and held in cotton ropes. As it was intended to ascertain what effect would be produced on the dogs, if engaged under a fire of the Maroons, the Spaniards, upon the word being given, fired their fusils, when the dogs pressed forward with the greatest fury, amidst the shouts of their keepers, whom they dragged along with almost irresistible force. Some of these animals, held by the ropes, and maddened by the shout of attack, absolutely seized the gun-stocks in the hands of the chasseurs, and tore pieces out of them. In fact, such was their furious impetuosity, that they were with difficulty stopped before they reached General Walpole, who was under the necessity of getting into his chaise most expeditiously; while the utmost exertions scarcely prevented them from seizing on the horses.

However, these dogs are chiefly intended for hunting runaway negros; and though they advance against a body of undisciplined blacks, nothing would be more ridiculous than to suppose them capable of charging a regular regiment. In hunting the negros, each chasseur is accompanied by two dogs, and armed with a straight sword or *couteau de chasse*; and we are informed that these blood-hounds, (when properly trained,) on coming up with the object of pursuit, will not kill him, unless resistance is offered, but bark and terrify him till he stops, when they crouch near him, and, by barking, give their keepers notice, who approach accordingly, and secure their prisoner. It seems they are sometimes accompanied by smaller dogs, of exquisite olfactory powers, called finders—a very striking proof that the blood hound of the West Indies is a very different animal from the talbot, since the nose of the latter was superior to any other of the dog tribe; while it is clear the olfactory organs of

## B O A R

the former must have been very defective, or they would have required no assistance from a *finder*. The unfortunate Maroons were panic struck on the arrival of the Spanish chasseurs in Jamaica; and though they had successfully opposed regular troops, (chiefly by ambuscade and surprise,) they surrendered, without once attempting to try their fortunes against animals by no means equal to armed men, and which required but an ordinary share of courage successfully to oppose. The Maroons had hitherto depended on their local knowledge, and the exquisite skill with which they concealed themselves, in their encounters with the troops of the island; and by no means on pitched battles or open fighting: and, aware that no hiding-place was proof against the scent of the dogs, they lost at once that address and persevering courage which had baffled very able officers, and made havoc amongst the disciplined legions brought to combat them.

Of the old English blood hound it may be observed, that he appears to possess all the good qualities of the blood hound of the West Indies, without that unnecessary fierceness which seems to be one of the most distinguishing characteristics of the latter. With an equal share of courage, the former possesses a finer scent, as well as a mild, docile, and familiar disposition; and by no means requires that excessive correction, which, it seems, is indispensable to the due submission of the trans-Atlantic dog.

In conclusion, it may be justly observed, that almost any kind of dog may be taught to pursue a human being; and certainly the fox-hound, the harrier, or the beagle, might be induced to trace the footsteps of a man with almost as much care as they are taught to chase a fox or a hare; these dogs would carry on any particular scent, when they are perfectly convinced they are to follow no other; and the ordinary rules of training are sufficient for the purpose.

**BLOOD SPAVIN.** See SPAVIN.

**BLOODY BUTTOCKS** was a grey Arabian, with a red mark on his hip: whence, according to a memorandum found among the papers of the late Mr. Croft, he derived his name.

**BLOODY HAND**, in the forest laws, is when a man is discovered with blood upon his hands or clothes; which circumstance constituted one of the four cases wherein a forester might arrest an offender.—The others, Back Bear, Dog Draw, and Stable Stand.

**BOAR, WILD.** The wild boar is the original of all the varieties we find in the hog; but is by no means so filthy and stupid an animal as that which has been domesticated by man: he is much smaller than the tame hog and does not vary in colour, but is always of an iron-grey, inclining to black. He roots the ground in a different manner from the common hog, for as this turns up the earth in little spots

here and there, so the wild boar ploughs it up like a furrow, and does irreparable mischief in the cultivated lands of the farmer. The tusks also of this animal are larger than in the tame breed, some of them being met with almost a foot long. These, as is well known, grow both from the upper and the lower jaw, bend upwards circularly, and are exceedingly sharp at the points. They differ from the tusks of the elephant in this, that they never fall; and it is remarkable of all the hog kind, that they never shed their teeth as other animals are seen to do. The tusks of the lower jaw are always the most to be dreaded, and are found to inflict very terrible wounds.

The wild boar can properly be called neither a solitary nor a gregarious animal. The three first years the whole litter follows the sow, and the family lives in a herd together. They are then called beasts of company, and unite their common forces

against the wolf, or the more formidable beasts of prey. Upon this their principle safety, while young, depends; for when attacked, they give each other mutual assistance, calling to each other with a very loud and fierce note; the strongest face the danger; they form a circle, and the weakest fall into the centre. In this position, few ravenous beasts dare venture to attack them, but pursue the chase where there is less resistance and danger. However, when the wild boar is come to a state of maturity, and when conscious of his own superior strength, he then walks the forest alone and fearless. At that time, he dreads no single creature, nor does he turn out of his way even for man himself. He does not seek danger, and he does not seem much to avoid it. This animal is therefore seldom attacked but at a disadvantage.

Hunting this animal was formerly a favourite amusement amongst the great in this country; and the chase of it is thus mentioned by an old writer:—A wild boar is called a pig of the sounder the first year of his age; a hog the second; a hog's steer the third; and a boar the fourth; when leaving the sounder, he is also termed a single or a sanglier. The common age of a boar is twenty-five or thirty years; they go to rut about December, and their great heat lasts about three weeks.

It is easier to take a boar in a toil in April or May than in any other season of the year, in consequence of their sleeping more soundly at that period, which is caused by their eating of strong herbs, and buds of trees, which moisten their brain and cause sleep. They feed on corn, fruits, acorns, chesnuts, beech mast, and all kinds of roots; when they are in marshy or watery places, they feed on water cresses and such things as they can find; and when they are near the sea-coast, they feed on cockles, muscles, oysters, and such like fish.

A boar most commonly lies in the strongest holds of thorns and thick bushes, and will stand the bay before he will forsake his den.

If he is hunted from a strong thick cover, he will be sure to go back the same way he came, if it be possible; and when he is roused, he never stops until he comes to the place where he thinks himself most secure.

If it so happen that there is a sounder of them together, then, if any break sounder, the rest will run that way; and

if he is hunted in a hold or forest where he was bred, it will be difficult to force him to quit it: sometimes he will take head, and seem to go drawing to the outsides of the covert; but it is only to hearken to the noise of the dogs; for he will return again, from whence he will be hardly compelled before night: but having broken out, and taken head endways, he will not be put out of his way by man nor beast, by voice, blowing, or any thing else.

A boar will not cry when he is killed, especially a great boar; but the sows and young ones will. In fleeing before the dogs, he neither doubleth, nor crosseth, nor useth such subtleties as other beasts of chase do, as being heavy and slow, so that the dogs are still in with him.

**HOW TO HUNT A BOAR AT FORCE WITH DOGS.** The season for hunting the wild boar begins about the middle of September, and ends in December, at which time they go a brimming.

It is not convenient to hunt a young boar of three years old at force; for he will stand up as long, if not longer, than any light deer that beareth but three in the top; but in the fourth year, you may hunt him at force as you do a hart at ten, and he will stand up as long. Therefore, if a huntsman goes too near a boar of four years old, he ought to mark whether he went timely to his den or couch, or not; for commonly those boars which tarry till daylight, go into their dens, following their paths or ways a long time, especially where they find fern or beech mast, whereon they feed; they are very hardy; and in the raising of this animal, one need not be afraid to come near him; for he values you not, but will lie still, and will not be reared by you alone.

But if you find a boar which soileth oftentimes, and which rooteth sometimes here and there, not staying long in a place, it is a sign that he has been scared, and withdraweth himself to some resting place, and such boars most commonly come to their dens or holds two or three hours before day, and the huntsman must take care how he comes near such a boar; for if he once finds him in the wind, or have the wind of his dogs, he will soon be gone.

It is also to be observed, that if a boar intends to tarry in his couch, he makes some doublings or crossings at the entrance of it, upon some highway or beaten path, and then lies down to rest; by which means a huntsman, being early

in the woods, may judge of his subtlety, and accordingly prepare to hunt him with dogs that are either hot spirited or temperate.

If it be a great boar, and one that hath lain long at rest, he must be hunted with many dogs, and such as will stick close to him; and the huntsman or spearman, on horseback, should ever be amongst them, charging the boar, and as much as possible to discourage him: for if you hunt such a boar with five or six couple of dogs, he will not regard them, and, when they have chased him a little, he will take courage and keep them at bay, still running upon any thing that he sees before him; but, if he perceives himself charged and hard laid into with dogs, he will be discouraged, and turn head and fly to some other place of refuge.

You ought also to set relays, which should be the best old staunch hounds of your kennel; for, if they should be young hounds, and such as are swift and rush to seize him before the others come up, they will be killed or spoiled by him. But if he be a boar that is accustomed to fly endways before the dogs, and to take the champagne country, then you may cast off four or five couple at first, and set all the rest at relays about the entrance of the fields where you think he is likely to flee; for such a boar will seldom keep the hounds at bay, unless he be forced; and when he does stand at bay, then the huntsman ought to ride in unto him as secretly and with as little noise as possible; and when he is near him, let him cast round about the place where he stands, and run upon him all at once, and it will be odds but that they will give him his death's wound with their spears or swords, provided they do not strike too low; for then he will defend the strokes with his snout; but be sure you keep not too long in a place, but use a quick motion.

You may also take notice, that if there be collars of bells about the dogs' necks, a boar will not so soon strike at them; but flee endways before them, and seldom stand at bay.

It is expedient to raise a boar out of the wood early in the morning, before he hath made water, for the burning of his bladder quickly makes him weary: when a boar is first raised, he is used to snuff in the wind, to smell what is with or against him.

Now, if you strike at him with sword or boar-spear, do not, as has been said, strike low; for then you will hit him on

the snout, which he values not, since he watches to take blows on his tushes or thereabouts; but, lifting up your hand, strike right down, and have a special care of your horse; for, if you strike and hurt him, so will he you if he can; therefore, in thus assaulting boars, the hunters must be very careful, for he will rush upon them with great fierceness.

However, he very rarely strikes a man till he is first wounded himself; but afterwards it behoves the hunter to be very wary, for he will run very fiercely, without fear, upon his pursuers; and if he receive not his mortal wound, he overthrows his adversary, unless he falls flat on the ground, when he needs not fear much harm; for his teeth cannot cut upwards but downwards; but with the female it is otherwise, for she will bite or tear any ways.

But further, as the hunting spears should be very broad and sharp, branching forth into certain forks, that the boar may not break through them upon the huntsman, so the best places to wound him are the middle of his forehead, between the eyelids, or else upon the shoulder, either of which is mortal.

Again, in case the boar makes head against the hunter, he must not fly for it, but meet him with his spear, holding one hand on the middle of it, the other at the end, standing one foot before the other, and having a watchful eye upon the beast, which way soever he winds or turns; for such is his nature, that sometimes he snatches the spear out of the hunter's hands, or recoils the force back again upon him: in these cases there is no remedy but for his companion to come up, and charge the boar with his spear, and then make a shew to wound him with his dart, but not casting it for fear of hurting the hunter.

This will make the boar turn upon the second person, to whose assistance the first must again come in, with which both will have work enough: nay, when the boar feels himself so wounded that he cannot live, were it not for the forks of the boar-spear, he would press upon the vanquisher and revenge his death.

And what place soever he bites, whether man or dog, the heat of his teeth causes an inflammation in the wound.

If therefore he does but touch the hair of the dog he burns it off; nay, huntsmen have tried the heat of his teeth by laying hairs on them as soon as he was dead, and they have shrivelled up as if touched with a hot iron.

The boar is a beast of such great force and so slow of foot, by reason of his heaviness, that he is not properly termed a beast of venery, as he chiefly trusts in his strength and his tusks for defence, and not to his feet; so that he is more properly to be hunted with stout mastiffs than with grayhounds, which cannot so well defend themselves from his fury.

Also, it spoils them from hunting other flying chases, by reason he leaves so strong a scent, so that they hunt with greater ease than at light chases, which are more painful for them to find and to hold the scent.

THE WAY TO KNOW A GREAT BOAR BY HIS FOOT, &c. To know him by his foot, the form and print of it ought to be great and large, the toes round and thick, the edge of the hoof worn and blunt, without cutting and paring the ground so much as the younger do; and the guards, which are his hinder claws or dew claws, should be great and open one from the other; the treading of his foot should be deep and large, which indicates the weightiness of his body, and his steps should be great and long.

By the length and depth of his rooting, his size may be known; because, a wild swine roots deeper than our ordinary hogs, their snouts being longer: and also by the length and largeness of his soil, when he walloweth in the mire; also, when he comes out of the soil, he will rub himself against a tree, by which his height will appear; as also when he sticks his tusks into it, by which the largeness of them will appear; they also observe the bigness of his cesses and the length of his den.

A boar is said to feed in the corn, but if in the meadows or fallow fields, they say he rooteth or wormeth, or ferneth; but when he feeds in a close, and rooteth not, they say he grasseth.

Such, if we are to believe the accounts handed down to us, was the method formerly practised of hunting the boar. This animal, though extinct in England, still continues to be hunted in France, and indeed most parts of the Continent; but, the chase of the boar, like some other departments of field sports, has partaken of the improvements of more modern times, and though the animal may still be roused by dogs, the fowling-piece has been substituted for the boar-spear. The method at present frequently adopted for the pursuit of the wild boar, particularly in France, is by sending small noisy

dogs into their woody retreats, while the hunters lie in ambush to shoot them as they pass along their different tracks; and on these occasions the hunters are frequently assisted by the neighbouring peasantry, as, from their local knowledge, they are enabled to place the hunters in the most advantageous situations. This method of pursuing the chase is distinguished by the name of *La Trac*.

Hog-hunting in India is a favourite diversion of the British officers, as well as the other Europeans residing in that part of the world. The wild swine in Hindoostan are smaller than those which are met with on the European continent. The hunters are mounted for the chase, and, with the assistance of dogs, pursue the hog (or wild boar) armed with a sort of javelin, which a little practice enables them to throw with almost unerring certainty. When a hog is roused, the hunters pursue him, and the first who comes up with the chase throws his javelin: should he miss his aim, the hog is still pursued by others, armed in the same way, until he is killed. The wild boar, (or hog, as he is called in India, and the diversion is there called hog-hunting,) on being roused, makes off as fast as possible; but he no sooner perceives himself attacked, than he turns upon his pursuers; and though the hunters themselves seldom receive much injury in the conflict, it is no uncommon occurrence for the horse to be severely wounded; sometimes he is killed. When the boar turns upon the hunter, the horse is very apt to rear, and by this means he affords the boar an opportunity of wounding him in the belly with his tusks. There are other dangers, however, to be apprehended when following this diversion, as the hunter is never secure from the sudden attack of ferocious, lurking wild beasts, with which that part of the world abounds, particularly the tiger. The flesh of the Indian wild hog is esteemed by the hunters, and is said to taste something like venison.

The Ethiopian wild boar is much allied to the common hog in appearance, but is distinguished from it by a pair of large semicircular lobes or wattles placed beneath the eyes. The snout also is much broader, and very strong and callous. It is a native of the hotter parts of Africa, and is a very fierce and dangerous animal. It resides principally in subterranean recesses, which it digs with its nose and hoofs; and, when attacked or pursued, it rushes on its adversaries with great force, striking like the common boar with

its tusks, which are capable of inflicting the most tremendous wounds.

These creatures inhabit the wildest, most uncultivated, and hottest parts of Africa, from Senegal to Congo; and they are also found in the island of Madagascar. The natives carefully avoid their retreats, since, from their savage nature, they often rush upon them unawares, and gore them with their tusks.

A boar of this species was, in 1765, sent by the governor of the Cape of Good Hope to the Prince of Orange. From confinement and attention, he became mild and gentle, except when offended, in which case, even those persons to whose care he was intrusted were afraid of him. In general, however, when the door of his cage was opened, he came out in perfect good humour, gaily frisked about in search of food, and greedily devoured whatever was given him. He was one day left alone in the court-yard for a few minutes, and, on the return of the keeper, was found busily digging into the earth, where, notwithstanding the cemented bricks of the pavement, he had made an amazingly large hole, with a view, as was afterwards discovered, of reaching a common sewer that passed at a considerable depth below. It was not without much trouble, and the assistance of several men, that his labour could be interrupted.

The motions of this animal were altogether much more agile than those of the common hog. When provoked, or rudely pushed, he always retired backward, keeping his head towards his assailant, and shaking his head or forcibly striking with it. His senses of smelling and hearing were wonderfully acute.

On the chase of the wild boar in France, Colonel Thornton makes the following observations:—

“The equipage destined for the chase of the wild boar is denominated *vautrait*. In great hunting establishments it forms a separate department, in which particular officers and attendants are employed. Large equipages for this sport are usually attended by a pack of fifteen or twenty couple of hounds. The huntsmen and whippers-in ought to be extremely expert. This chase is very fatiguing: the huntsmen are obliged to shout incessantly, to make the dogs follow, as they are frequently discouraged, especially if they are pursuing an old boar. It requires mettlesome and vigorous horses; and the riders must not be afraid of the branches in the thick recesses of the

forest, into which they are obliged to penetrate.

It is extremely difficult to procure hounds well trained for hunting the boar, and this instruction requires great patience and attention; not that a young hound will not at first pursue the animal; but his scent sometimes disgusts, and the country, covered with thickets and morasses, discourages him. A boar is not so easily hunted down as a stag; and, let the establishment be ever so excellent, the chase seldom lasts less than four or five hours. Sometimes the animal is checked by firing a gun—or he is pursued by mastiffs and greyhounds. Chases have been known to continue two whole days; and at last the hunters could not have taken the boar but by shooting him, on the third day.

When the boar finds himself driven to the last extremity, he does not run forward, but frequently turns, keeping for a considerable time near the same spot, and seeking to make the dogs start some other game. When he is done up, he foams much, advances only by leaps and bounds, throws himself into some marsh, or sets his back against a thicket, facing the dogs, and defending himself with incredible fury. It is then that the whippers-in must give effectual support to their dogs, and endeavour to dislodge the animal; but if he keeps at bay, it is proper to prevent the dogs from approaching too near. The whippers-in enter the thicket with precaution: one of them alights, approaches the boar, and plunges his hunting-knife into the small of his back. The man who inflicts the wound must be very alert, and instantly run off a contrary way; for the boar always turns towards the side on which he feels himself wounded. If, however, he should prove so furious as to endanger the sportsmen and the dogs, the best way is to kill him with a gun or pistol: this is a privilege or honour reserved for the leader of the company, and is resorted to only at the last extremity. The whippers-in then sound the death of the animal, and encourage the dogs to trample on him. Having cut off the testicles, which would cause the flesh to contract a very disagreeable smell, and the fore foot, which is given to the huntsman, who presents it to the leader of the company, the boar is carried off. Before they return, the dogs are inspected, and those that have received wounds are dressed, as the huntsman ought to be provided with needles, thread, and every thing necessary for that purpose.

Dogs do not eat the flesh of the boar with so much avidity as that of the stag; nor must it ever be presented to them raw. All that is in general given them is the shoulders and the intestines cut in pieces, and boiled in water.

In some parts, small bells are fastened to the necks of hounds that hunt the boar and the wolf. If it is not intended to hunt down the boar, but only to shoot him, an equipage becomes perfectly useless; one or two blood-hounds, and a few good hounds, are, in this case, quite sufficient. Nay, you need then only employ the mastiffs with which the gamekeepers traverse the forests where the boars couch, and drive them towards the spot where the hunters are posted.

In Germany, and occasionally in France, very fine sport is obtained by hunting of boars, and likewise of stags, with 'toils. An enclosure is formed with toils and pitch-forks, round the thickets into which the boars have been driven. A huntsman sets his blood-hound upon the scent, and follows him till he has reared the game. Five or six hounds are then slipped: this number is sufficient to hunt a large boar; but if there are several, the whole pack is taken.

In the first case, it is proper to accompany the hounds with a few dogs, produced by crossing the breed of the mastiff with the hound: these animals, which are extremely ardent, will closely press the boar, and drive him round the enclosure. The dogs are powerfully supported with the voice and the horn, and are followed close to prevent the boar from making head against them. After the chase has continued some time, the large mastiffs and greyhounds are then slipped, and these rush upon the boar with fury. The huntsmen advance; one pierces the animal with his hunting-knife in the small of the back; the others, armed with sticks, are ready to receive him, in case he should make towards the person who wounded him, and strike him upon the snout, keeping him off with the end of the stick, till they have despatched him. When the proposed number of boars are taken, the dogs are called off."

It would, at first view of the case, appear hardly credible that a boar should stand so long before hounds; but this animal, in a state of unlimited freedom, is, beyond all question, a very different creature from the heavy, sluggish, domesticated boar, which frequently appears scarce able to support his own unwieldy bulk.

From a private letter of the late Colonel Thornton to a friend, I copy the following observations respecting the wild boar, and also of the pursuit of it:—

"I sent you a paper which contained something about a noble wild boar, which I ordered to be hunted; and, when killed, in Chambord, to send it here at my expense; and thus to try to let such sportsmen here (London) as never saw one, be able to judge for themselves. Accordingly, it being arrived, every person that heard of it came to see it. It was hung up at a venison-dealer's in Old Bond Street. The concourse of people was so great, that the man could not get out of, or others enter, his shop. It is to-day (January 15, 1819) being cut up into forty pieces, to be disposed of to various friends; and I have given the skin, head, &c. all unmutilated, to Bullock, to show them, with the account of the different balls he received ere he would resign to hounds or men. He is by no means the largest boar I have killed; but he is a terrible-looking fellow, more dangerous than one much older, for then their tusches grow thicker, become curved, and the animal is more inactive. He wounded many of the hounds, but only killed, I believe, three. A couple of vermin terriers plagued him the most, as he could not get his tusches to bear on them. The last final shaft was a *lingo*, which, I sec, broke three of his ribs, and passed through him. The number of balls he received I shall examine and relate. I understand, he stood a run of full forty miles. But I am sure I ran one at least one hundred and forty; and then he was not done up, though constantly viewed from half past eleven till past ten the next day, relays of hounds being uncoupled close at him every three or four hours. What other animal can show such game and bottom?

We dine to-day a party on his loin or saddle, which was where he received his death wound. The wound, as I have already observed, was inflicted by a *lingo*, which is a piece of iron or lead, formed something like a weaver's shuttle, of the weight of two or three balls, and made to fit the calibre of the gun. It is a sort of bolt, which, if it strike into flesh, it goes deeper: if it touches a bone, it then turns itself broadways; and thus, though a ball would only have broken one rib, it broke three, close up to the back. The number of balls that he received shall be the subject of my next letter."—This boar, it seems, was three years old, was run by

fleet fox-hounds, and during the progress of the chase crossed four rivers.

**BOBBING.** A method of taking eels. It is practised in a boat, with a large bunch of worms suspended by a strong cord from a pole or stout rod, in the following manner. First of all, you must procure a large quantity of worms, (marsh worms are best, though lobbs will do,) and string them on worsted or coarse thread, by passing a needle through them from head to tail, until you have as many strung as will form a bunch as large as a good-sized turnip; then fasten them on the line, so that all the ends may hang level: in the middle is placed a piece of lead, of a conical or bell form, the broad end downwards, which may be got at any of the fishing-tackle shops, made for the purpose; thus prepared, cast the baits into the water gently, let them sink to the bottom, and then keep raising them a few inches from the ground, and dropping them again, until you have a bite, which is easily perceived, as the eel tugs very strongly: be as expert as possible, at the same time steady, in raising your line, so that your fish, in dropping off, may fall into the boat. Immense numbers are taken by this method. During the hot weather, always fish or bob in shoal, or rather shallow water, and out of the stream. During the night most are taken; but they will lay hold freely in the day-time. Rivers in which the tide flows afford the best success, particularly during ebb-tide.

**BOG SPAVIN.** See SPAVIN.

**BOLTING.** When a fox, having taken to ground, has been dug to, and forced out, he is said to have been *bolted*. Also, a rabbit or a badger *bolt*, when they quit their earth. A race-horse *bolts* when he obstinately runs off the course.

**BONE SPAVIN.** See SPAVIN.

**BONNY BLACK**, the property of the Duke of Rutland, was got by Black Hearty, (a son of the Byerley Turk); dam by a Persian stallion. Bonny Black was the best of her day, as regarded speed and bottom. At three years old, she beat a six-year-old horse belonging to Mr. Frampton—10 stone each; at four years old, she won the gold cup at Hambleton, and the following year bore off the same prize; at six years old, she beat Lord Harvey's Merriman, eight years old, giving him 3 stone. She also beat Hackwood in a match, 8 stone each, after which her owner offered to run her four times over the B. C. at Newmarket, (sixteen miles,) without rubbing, for 1000 guineas, against any

horse or mare in the kingdom. This challenge not being accepted, she became a brood mare in his grace's stud. Bonny Black was foaled in 1715.

**BORING.** A useless and cruel operation, formerly practised for a strain of the horse's shoulder, or, as they termed it, "a wrench." It consisted in cutting a hole in the skin of the shoulder: into this they introduced the stem of a tobacco pipe, blowing up the cellular membrane in the same way a butcher does that of veal: a flat piece of red-hot iron was then thrust in for several inches, and worked about in different directions. This cruel and unnecessary operation has long been buried in deserved oblivion.

**BOTTS.** There is a great diversity of opinion about these insects, being said by some practitioners to produce very formidable diseases, and sometimes even to kill the horse; on the other hand, they are said to be productive of no mischief at all. That they produce no harm, seems to be shown by their being found in horses which die from accidents, or are killed, proving, at any rate, that their presence in the stomach was not the cause of death. Again, it has been thought that they might be of service in triturating the food in the stomach, as their covering is nearly horny; and Mr. Bracy Clark, who has written a very excellent paper on them, seems to think that they prevent farcy and glanders. There have been cases in which the botts have eaten holes through the stomach; in a remarkable one, when the horse was opened after death, the contents of the stomach were found in the cavity of the peritoneum, and there were also some found sticking between the coats of the stomach, proving that they had not got into the peritoneum, by the action of the gastric juice upon the stomach. The insect has two sharp hooks, by which it attaches itself to the stomach, and it prefers the cuticular part rather than the more sensible one. They cannot be removed by medicine; and when they pass out at the anus, it is because they have of their own accord left the stomach. They are deposited on the skin of the horse in an egg by a fly; the horse, by licking his skin, takes them into his stomach, where they are hatched and adhere. After having staid there some time, they pass out at the anus, and become a fly. We possess nothing capable of killing them; for after opium has been given to a horse labouring under locked jaw, in doses of one ounce every day, for a week, botts

were found in the stomach, perfectly alive; the same when tobacco has been employed, and even arsenic and corrosive sublimate.

BOW. The bow, which is justly called "by Ascham, the chief instrument of archery, was made in former times of a variety of different woods, as may be gathered from the statute on archery of the 33 Henry VIII. c. 9, in which it is enacted, that every bowyer (living without the city of London) for one bow of yew shall make four of elm, wych, hazel, ash, or other wood apt for the same." The author of the *Toxophilus*, however, speaking of the woods proper for bow making, says that "for brasell, elme, wych, and ashe, experience doth prove them to be but meane for bowes, and so to conclude, yew, of all other things, is that whereof perfect shooting would have a bowe made. This wood, as it is nowe general and common amongst Englishmen, so it hath continued from long time."

The experience of our ancestors, which led them to prefer the yew to all other woods, taught them also the superior value of foreign yew to that which grew in England; so high indeed was foreign yew esteemed, that a number of statutes were passed in the reigns of different kings, relative to the importation of bow staves; by some of which it was ordered that they should be brought from Venice; by others, that a certain number should be imported with every butt of malmsey or Tyre wine; with a variety of other regulations, which, in a practical notice like the present, it is needless to enumerate.

Before, and for sometime after, the reign of Elizabeth, bows were made of one single piece of yew till the scarcity of foreign staves induced bowyers to substitute English yew, which being in itself too brittle and full of knots to make a bow alone, they tried the experiment of joining a piece of tough wood with it: the result answered their highest expectations, and from that time *backed bows* became in general estimation; still, however, though backed bows have gained considerable reputation, Mr. Roberts, in his *English Bowman*, observes, that "we know by experience that the best modern *self yew* bows (a bow made of one piece is called a *self bow* in contra-distinction to *backed bows*) have never been exceeded in *certainty* or *length* of cast by the best modern *backed bows*," by which it will be seen that a backed bow does not exceed a self bow, except that it is thought by some to be

pleasanter and easier to draw, especially in the last inch, and of quicker cast.

Seeing that we have made two kinds of bows, we shall give a description of each, beginning with the self bow:—Ascham observes, that a bow is known much as good counsel is known, by the end and profit of it; yet both a bow and good counsel may be made both better and worse, by well or ill handling of them, as oftentimes happens. And as a man both must and will take counsel of a wise and honest man, though he see not the end of it, so must a shooter of necessity trust an honest and good bowyer for a good bow before he knows the goodness of it. And as a wise man will take plenty of counsel beforehand whatsoever need, so a shooter should always have three or four bows in store whatsoever happens. Therefore, I will tell you some tokens in a bow, that you shall be seldom deceived. If you come into a shop and find a bow that is small, long, heavy, and strong, lying straight, not winding nor spoiled with knot-gall, wind-shake, wem-fret, or pinch, buy that bow on my warrant. The best colour of a bow that I find, is when the back and the belly in working be much after one manner, for such, oftentimes in using, do prove like virgin wax or gold; having a fine long grain, even from the one end of the bow to the other; the short grain, although such prove good sometimes, are for the most part very brittle. Of the making of the bow I will not say much, lest I should seem to enter into another man's occupation, in which I have no skill. Yet I should wish all bowyers to season their staves well, to work them and sink them well, to give them heats convenient, and tylleringes plenty.

Every bow is made either of a bough, of a plant, or of the bole of the tree. The bough is commonly very knotty and full of pins, weak, of small pith, and will soon follow the string, and seldom wears to any fair colour; yet, for children and young beginners, it may do well enough. The plant proves often good if it be of good and clear growth, and for the pith of it, is quick enough of cast; it will ply and bend far before it breaks, as all other young things do. The bole of the tree is cleanest, without knot or pin. Of the origin of *backed bows* we have already spoken; also of the fact, that a *good backed bow* is not superior to a good *self bow*. It is said however that they are more pleasant and easy in the drawing; which, with the

circumstance of a *good backed* bow being more easily procured than a good self bow, has been, and doubtless will be, the cause of their preserving the reputation which they have not unjustly acquired.

In the construction of backed bows they are generally composed of two pieces, the back and the belly, though occasionally an intermediate slip of quick casting wood has been introduced between the two, and has been found to answer remarkably well: the belly inside, or round side of the bow, was for some time made of yew, till fustic was discovered to be quicker in its action; of late years a variety of different woods have been imported, which have been used with considerable success in bow making.

**BOW, A BEARING.** A bow that casts an arrow well.

**BOW-ARM.** The arm employed in holding the bow.

**BOW, BACKED.** A bow, the back of which is a distinct piece glued upon the belly.

**BOW-HAND.** The hand which holds the bow.

**BOW MEETING.** An assemblage of archers, most generally for the purpose of shooting for a prize: the term is also sometimes applied to those meetings which are for the purpose of exercise only.

**BOW SHOT.** The distance which an arrow flies from a bow.

**BOW STAVE.** A stave of wood, cut ready for being shaped into a bow.

**BOWELS. (INFLAMMATION OF.)** The bowels of all animals are very liable to disease, the most serious of which is inflammation; and this occurs more frequently in horses than in any other quadruped. Inflammation of the bowels occurs in three distinct parts: first, in the mucous coat of the intestines; in those cases in which horses die from excessive purging, the treatment is different on account of the action of the aloes, which, if used in large quantities, becomes caustic to the intestines, so as to induce gangrene. Opium will stop the purging but we rarely see a case recover, in which a sufficient quantity of opium has been given, so as to produce astringency. It is best to give chalk, with about two drachms of the tincture of opium, and apply turpentine embrocations to the abdomen, the horse, at the same time, wearing sheep skins.—Blisters are but of little use, as the disease requires immediate relief. This inflammation of the mucous coat of the bowels, is, as I have said, always brought on by

excessive purging.—2nd. Inflammation of the substance of the bowels; the pulse is in this disease hard, and from 70 to 80 in a minute, whilst its natural state is about 40; the breathing is difficult, the ears and legs are cold, the horse lies down and strikes his belly with his legs, but he does not attempt to lie on his back; the pain is not so acute as in spasm, nor does it come on so suddenly; these differences, with the hardness of the pulse, will distinguish inflammation of the substance of the bowels from spasm. In the treatment of this disease, we must have recourse to large bleedings, on which every thing depends; we should take away 18 or 20 pints of blood, and indeed, rather be guided by the pulse than the quantity of blood we have taken away; we should throw up by the rectum, gallons of warm water and soft soap; for, if these remedies be not used, the bowels will become gangrenous or nearly in a state of mortification.—3rd. Inflammation of the peritoneal coat of the bowels sometimes takes place, but it is seldom seen, except as the effect of castration.

**BOWEL-GALLED.** This is a laceration between the elbow of the fore leg and the ribs of the horse, occasioned by the tightness and friction of the girths. It should be frequently bathed with a solution of sugar of lead in water, in the proportion of one ounce of the sugar of lead to two quarts of water; taking care that the girths do not press again on the same place, which may be prevented by means of a crupper.

**BOWYER,** a maker of bows.

**BRACE**—a pair; a couple; a brace:—a pair is two united by nature (par); a couple, by an occasional chain (copula); and a brace, by a noose or tie.—A pair of swans; a couple of hounds; a brace of partridges. A pair is male and female; a couple, two accidental companions; a brace, tied together by the sportsman.

**BRACER,** an implement used in archery to protect the left arm from being injured by the string striking against it. It is generally made of stout leather, the outside of which should be well polished, and it should be fastened to the arm with a buckle and strap. The price of a bracer is five shillings. This implement, by many, is called a brace.

**BRAMBLE-NET,** a net, otherwise called a hallier.—See **NET**.

**BRAN,** is a very useful article of diet for sick horses, and as a preparative for purgative medicines. Good bran should

be sweet and perfectly free from any musty smell, which it often acquires by keeping in damp places. Pollard is a superior kind of bran, which is sometimes to be preferred, when more nutriment is wanted in the mash than you can get from common bran. Bran mashes are made by pouring boiling water on to bran, and letting it stand in the pail until it is sufficiently cool. Bran is of an opening quality, and, therefore, it is very proper for horses that have but little exercise; mixed occasionally with oats or split peas.

**BREAKING DOGS.** Under this head I shall first observe, that, by proper attention to breeding, the sportsman will have very little trouble in training. A well-bred dog, either setter or pointer, will generally require very little instruction, as he will, particularly if taken out young, set and back of his own accord.

I know it is a received opinion that those dogs which are very difficult to reduce to the required subordination, prove, when thoroughly subdued, superior to all others. From experience, I will venture to pronounce this a hasty opinion:—these hardy, untractable animals, are chiefly the offspring of the pointer and setter, or, at least, cross bred; and are, after all the painful flagellation, and endless trouble in training, no better than a good dog of a milder and more pliable disposition, nor yet so good, as unqualified reliance can scarcely ever be placed on them: indeed, after repeated trials of dogs of this description, I have become so disgusted with them, that I would not, on any account, take the trouble of another experiment.

In the first place, then, it is indispensably necessary that the sportsman should procure dogs whose breed is unexceptionably good, as well-bred dogs are more than half broke the moment you take them into the field. The dog is an animal possessed of an uncommon degree of sagacity;—in short, he has *reasoning powers* to a very great extent, which may be converted to the pleasure or the service of his master; yet, in this respect, dogs will be found to vary very much; and while some will appear to exhibit instinct merely, others will be found to evince a degree of acuteness very similar to reason. There is a countless variety of the dog tribe, many of the nondescript ramifications of which, with an ugly and diminutive form, seem to sink much below the general level of the canine tribe in sagacity, while the nobler kinds appear to rise in the scale of importance in proportion as they are judiciously bred,

and afterwards cherished by the fostering care of their human protector.

The most sagacious of all the varieties of this highly interesting animal is, without dispute, the Newfoundland dog. His olfactory organs are of the first order; yet, as from his heavy, long, and loose form, he is unable to support the fatigue of a day's range, he, on this account alone, is ill calculated for the shooting sportsman. Similarly important disqualifying observations would apply to most of the other varieties of the dog, till we come to the pointer and setter, which appear altogether most admirably adapted to the purpose for which they are so generally used. We may, however, remark, that the mere pointing or setting is by no means confined to these two particular kinds; on the contrary, terriers, hounds, and all dogs inclined to hunt, may be easily taught to point or set; or, in other words, to pause or stop, on their approaching game. Indeed, there are few dogs given to hunting but will point naturally, in the course of a little time, which arises no doubt from the following reason: as a young dog ascertains his proximity to game by his sense of smell, so, on his near approach, he is eager to seize it; but finding, after repeated trials, that he is unable to accomplish his purpose, he becomes more circumspect or wary, and will be observed to pause for a short space, and then make a sudden rush to secure his object. This pause is, no doubt, for the purpose of ascertaining, by his olfactory organs, the exact spot where the game is seated; and the observation of this very circumstance, there is not a doubt, originated the idea of the setting dog; the sportsman carefully improving, by education, a quality which he easily discovered would so essentially conduce to the pleasures of the field.

Taking it for granted, therefore, that all dogs which will range for game will naturally pause or set, yet none of the various kinds seems so quickly to adopt this sagacious manœuvre as the pointer or setter; nor is any one of them every way so admirably adapted as an auxiliary to the fowling-piece. Next to the Newfoundland dog, on the score of powerful instinct, or animal reasoning, may be ranked the pointer: his countenance is open, intelligent, and expressive; while his speed, strength, and persevering spirit, enable him to continue the chase for a length of time almost incredible.

For those who follow the diversion very ardently, and are out almost every day,

the setter will generally be found a valuable acquisition; but those who enjoy the fascinating amusement of shooting only occasionally, will find greater satisfaction in the more steady and better regulated exertions of the pointer; and, indeed, I have found good pointers (my own, for instance,) endure quite as much fatigue as the setter. Pointers are very susceptible of education, are easily broke or trained, and not so apt to forget their lessons as the setter.

The first object to be considered in training a dog, is the animal's temper: some dogs require frequent and severe correction, while, with others, mild treatment, and even encouragement, are indispensable. The most philosophic patience is an admirable quality in a dog-breaker, as many otherwise excellent dogs have been ruined by ignorance and brutal passion.

Well-bred dogs generally begin to hunt at an early period, though it will sometimes happen (but not often) that a dog will continue so long before he manifests a disposition for hunting, as to induce a suspicion that he is good for nothing.—Let no sportsman be too hasty in forming this conclusion. At the age of five or six months, or even earlier, you should allow your dog to accompany you, when you walk out, supposing it to be in the lanes or elsewhere; and, occasionally, lead him in a cord, or couple him with another dog. He may be allowed to ramble to a certain distance, so as not to be out of call; occasionally making him come behind you at the word *back*. The fewer words that are used in each lesson the better, which should be always the same, of the plainest sound, as well as the most distinct from each other, as the dog is guided by the sound alone; any meaning beyond what the sound and tone convey, is, of course, above the capacity of a quadruped.

It may be as well to teach him, at the same time, words of caution, such, for instance, as *take heed*; as well as of encouragement, as *good boy!* the latter should not be *used profusely*, but applied in the most judicious manner, as encouragement is very apt to induce a dog to commit errors. A plurality of teachers should, if possible, be avoided; one instructor being amply sufficient.

Whenever a dog is corrected, either at this period or afterwards in the field, he should not be suffered to leave you till he is satisfied that you intend him no further chastisement: for example, if a dog be

guilty of so great a fault, when hunting, as to render a severe flogging indispensable, you should not allow him to run away immediately after the flagellation, but compel him to remain at your feet for some seconds or a minute, otherwise, you will not be able to catch him, perhaps, should he require a second chastisement. When a severe flogging is necessary, it is advisable to put a cord round the neck of the dog, by which means the punishment may be administered more effectually.

After the dog has been thus brought under subjection, or reduced to the requisite obedience, at any period, from the age of eight to eighteen months, according as he is strong and healthy, he may be taken into the field, either with or without another dog, and suffered to hunt whatever he pleases, (except sheep or domestic animals,) and, in fact, to run riot. Larks, as they so frequently present themselves, will, most likely, be the first object of his attention; these he will spring and chase very eagerly; if partridges come in his way, he will do the same, with this difference only, that his eagerness will much increase; it will be still greater should he come in contact with a pheasant; and if a hare happen to rise before him, he will not fail to chase, with all imaginable ardour, and will, most likely, open in the pursuit. In this way he may be indulged till such time as he has become so attached to the sport that he may be checked without the least danger of his being overfaced, and thus induced to blink his game, or be otherwise rendered shy.

In a short period you will perceive him draw more cautiously upon the scent; on approaching his object, he will pause even at a lark; but when a partridge happens to be before him, his pause or stop will be more steady, and his manner altogether much more earnest; and the difference of the object will be very clearly manifested in his countenance.

If, contrary to expectation, he should manifest no disposition to pause or stop, after having been taken into the field half a dozen times, every time he springs the game, he must be brought back to the spot whence it rose, and compelled to crouch; the word *toho!* must be angrily spoken, and the whip used, if, after repeated cautions, he should pay no attention.

He should now be taken out with an old steady dog, and whenever he comes to a point, the word *toho!* should be used, and afterward the whip, should the word

prove unavailing. Whenever he sets, approach him at your regular pace, but seem not in a hurry, (as, if you run, he will be very apt to do the same) and stand by him for a few seconds; if the birds do not rise, he should be allowed to advance, by saying, *hold up!* be mindful, however, that he does not advance too rapidly; and, in order to effect this, make use of words expressive of caution, as *take heed!* When the old dog points, the young one should be taught to *back*, which may be accomplished in the following manner:—As soon as the old dog settles to a point, supposing the young one happens to be at a distance, he must be stopped, as the moment he perceives the point, he would, if left to himself, rush eagerly up: however, he must be prevented from so doing, by calling out *toho!* at the same time holding up your hand.—If he obey not by gentle means, recourse must be had to the whip. By these means he will, most likely, soon become very steady; for dog-breaking, if attended to at a proper period, and in a proper manner, does not give half the trouble that is generally supposed.—Holding up the hand is the signal for the dog to *back*; and, in a little time, whenever he sees it, he will immediately stop, though he may be at the other end of the field, or at a considerable distance.

At the same time, he should be taught to quarter his ground in a proper manner, as well as not to break fence. In beating a field, care should be taken to give him the wind; or, at least, he should never be suffered to run directly with the wind: if it blow in his face, so much the better; but a dog will hunt very well with a side wind. The dog should cross about twenty yards before the shooter, and if, after running down the field, he should not cross up again at about the distance just mentioned, he should be called to or whistled, and a wave of the hand should direct him across the field; unless indeed he catch scent, when he should be suffered, of course, to follow it. In case of attempting to *break fence*, he should be instantly whistled to, or called by name in an angry tone, using at the same time the words *'ware fence!* This will, in all probability, soon produce the requisite obedience; but should he refuse to obey the whistle or call, the *whip* must produce what more gentle means are unable to effect. If he refuses to pay attention to the whistle, he should receive a few stripes, (more or less, according to the disposition of the animal) the whistle occasionally used during the

operation, and continue to be so corrected, should he not return implicit obedience when called to. Thus he will soon become pleasingly tractable.

We will suppose that the dog is already steady at partridge; yet if he happens to approach a hare, he will scarcely fail to rush at her—at all events he will chase when she rises. In this case, he must be brought back to the place from whence he run, and made to crouch as before described, using the words *'ware hare!* or *'ware chase!*

Hitherto, I have supposed that the dog-breaker has been engaged with a mild, good-tempered animal, which will be easily rendered tractable by the means just described; there are, however, dogs of a very different description, which require an excess of flogging, aided by other coercive measures, in order to enforce that indispensable degree of subordination, without which, shooting, so delightful with well-trained pointers, is rendered irksome and vexatious.

If repeated severe flogging fail to accomplish the object of the sportsman, recourse must be had to the *trash-cord*, or rather *drag-cord*. This is a cord something like a clock-line, about twelve or fourteen yards in length, to be fastened round the dog's neck; on the moors the dog will run with twenty yards, while twelve or fourteen will soon tire him in enclosed grounds: the greater the length of cord, however, that can be used with propriety, the better: the cord may be shortened as the dog becomes fatigued. By the help of this cord, you will be able to stop him whenever you please. We will suppose that he makes a point: should he attempt to run in, you must check him as smartly as possible, making use of the word *toho!* and the whip also if you think proper. This cord will be very useful should the dog not come in when called, &c. If, after some little practice with the drag-cord, the dog perseveres in springing his game, or continues otherwise refractory, the *spiked collar* must be used. The *spiked collar* is merely a leathern strap, through which are inserted a dozen or more small nails, the points of which should extend half-an-inch beyond the surface of the inside. On the outside a piece of leather must be sewed over the heads of the nails, to prevent their starting back when the dog presses upon their points. This is to be buckled round the dog's neck, the points of the nails inwards, and the drag cord attached to it.

Thus, when it becomes necessary to check him on his attempting to run in, or behaving otherwise unruly, the admonition, or rather correction, will be much more impressive; in a little time, his neck will be very sore; and he must be contumacious beyond measure if this mode of punishment does not produce the desired effect.

The most difficult part of dog breaking is, perhaps, reducing the animal to perfect obedience in respect to hares. In the first instance, a young dog will eagerly pursue larks, or thrushes, or in fact any of the feathered tribe which he happens to meet with: the partridge being a larger object, and making considerable noise when taking wing, will be pursued by him with much more ardour; a similar remark will equally apply to the pheasant, which he will still more eagerly pursue: but very soon discovering the attempt to be hopeless, he will shorten the distance of his pursuit, and ultimately abandon the chase altogether. Not so, however, with the hare; for perceiving that it does not leave the ground, but runs like himself, he will not very easily relinquish the hope of overtaking her, but will rush forward with ungovernable ardour, and, even when lost sight of, will continue to follow the chase by the nose. But there are few dogs which may not be rendered steady in respect to hares by the means which we have pointed out, and that much sooner, of course, where hares are numerous, than where they are seldom met with. There is one effectual mode of reducing a dog to obedience in this respect, should the whip, the drag cord, and the spiked collar, fail of the desired effect. For this purpose, a living hare should be procured, to the neck of which a cord should be fastened; to the other end of the cord (which may be six or seven yards in length) should be attached a wire, which wire should be thrust through the snout or cartilaginous part of the dog's nose. The hare will, of course, spring forward at the sight of the dog, which will not fail to cause the most acute pain to the latter; the whip should be applied at the same time, accompanied with the words '*ware hare!*'—On all occasions of correction, the requisite word should uniformly accompany the punishment. This may be regarded, perhaps, as the excess of severity, and should never be resorted to but when all milder means have been repeatedly tried in vain. To prevent an obstinate dog chasing hares, I have sometimes seen the fowling-piece used as a re-

medy. It may be regarded as a desperate one, which, though it will generally have the desired effect, should be used with the utmost circumspection. If a dog is to be shot at, care should be taken that he is at a sufficient distance, as well as to hit him about the rump; otherwise you run great risk of *killing* him.

In the earlier part of these remarks I have mentioned mild-tempered dogs. It will be requisite here to observe, that well-bred dogs are occasionally met with so very shy as to require encouragement rather than correction: dogs of this description may sometimes prove excellent; but I must confess I do not like to see a *very shy dog*. Animals of this sort should never be taken out with dogs that need much rating or flogging, as the very sight of the whip alarms them to such a degree that they will not stir from behind you. Nothing is more difficult than to manage very shy dogs: they must be encouraged to hunt; and if they commit an error, the means of correction are difficult, and sometimes impossible; the least severity will most likely make them *blink* (*blinking* is when a dog finds game, and, on being spoken to, draws off, and runs behind you, and frequently without being spoken to) their game; and when once this habit is contracted, it will require more than ordinary pains to eradicate it.

As I have spoken of the various methods to be employed to render a dog steady at the point, to range, and also to *back*, I must observe, in this place, that a dog should never be suffered to *break fence*; or, in other words, to leave the field till you are ready to accompany him, as much mischief may ensue from his being suffered to ramble out of sight, or to a great distance. On his attempting to break fence, the whistle should be used, the dog should be called by his name in an angry tone, followed by the words, '*ware fence!*' the whip, &c. to be resorted to as in other cases, if necessary, to procure obedience.

Generally speaking, as little noise as possible should be made. The voice or the whistle should never be used, but when absolutely demanded; the dog will thus hunt steadier; and if you accustom him to the motion of your hand, he will regularly look for the signal whenever he is at a loss.

It is thought by some, that dogs *broke on the grouse mountains* are superior as to *ranging*: this is doubtful, if not a mistaken notion altogether. In this respect, much will depend upon the animal himself.

Young dogs in general hunt with their noses closer to the ground than old ones, and are apt to puzzle on the scent a considerable time after the game has left the spot. A little practice will, however, most likely remedy these defects; if not, recourse must be had to the *muzzle-peg*, an instrument very well known amongst sportsmen, but which I will, nevertheless, describe. The muzzle-peg is merely a piece of wood hollowed out and formed at one end so as to fit or receive the under jaw of the dog. From the dog's nose to the other end, projecting about nine inches, it is merely a round stick rather thicker than a man's thumb; though some persons, instead of one of these round projecting sticks, prefer two, forming an angle with the dog's nose. At the upper end of that part which is placed under the dog's nether jaw, two longitudinal holes or slits are made, through which a strap is inserted, which is buckled behind the animal's ears; while the other end of the thick part of the muzzle-peg, or that which comes under the canine teeth, or fangs, is perforated with two holes, through which a leather thong is drawn and tied immediately behind the fangs just mentioned. With this instrument, so fastened, the dog may be hunted without the least injury. At the first putting on, however, he will use every effort to rid himself of so disagreeable a companion, nor will he hunt, till he has satisfied himself of the inefficacy of his utmost exertions to get free from this unpleasant restraint. At length, he will become familiar with the instrument, and run with it as unconcernedly as possible; and it will make him carry his head well up, as well as prevent him chopping young hares, or mouthing in any way. A dog that *rakes* (that is, runs with his nose close to the ground) and follows his game by the track, will generally spring it. Whenever, therefore, a young dog is seen to follow the track of a partridge (down wind in particular) he should be called to in an angry tone, *hold up!* he will then become uneasy, going first to one side and then to the other till the wind brings him the scent. If, after a short period, he should persevere in keeping his nose to the ground, and in following the track, recourse must be had to the instrument I have just described.

Grouse, partridges, or any kind of game, lie much better to a dog that winds them, than to one which approaches by the track. The dog that winds the scent approaches the game by degrees, and that

more or less as he finds it wild or otherwise, which he is enabled to discover by the scent which is emitted; and though grouse or partridge see him hunt round them, they will be much less alarmed than when they observe him following their track, and suffer his near approach; or, in other words, *lie well*. The reason seems evident:—the dog, I apprehend, is seen by the birds (generally speaking) as soon as he enters the field; or, at all events, at a very considerable distance; and the moment they perceive him approach by the track, they take the alarm, supposing themselves discovered, or, at least, very likely to be discovered; but watching, as they assuredly do, the motions of the dog, and observing that he does not follow the track along which they have run, they conceive themselves undiscovered, and thus allow the dog to come to a steady point. It may, moreover, be further remarked, that a dog which carries his head high will always find the most game, to say nothing of finding it in a handsome style.

A young dog should be kept regularly to his work, if possible, until he become quite staunch. Great care should be taken with him the first season he is shot over, as it seldom fails to determine his worth: at this period, numbers of otherwise valuable dogs are ruined by improper treatment, particularly by ignorant, passionate game-keepers and dog-breakers: no fault, however, should be allowed to escape correction or *reproof*. I do not mean that the dog should be flogged for every trivial mistake, but that the most trifling error should be noticed by sounds or symptoms of displeasure; and, proceeding this way, you should administer correction according to the degree of crime.

We will suppose the young dog broke, and taken out to put into effectual practice all his previous instruction. On the first shot, particularly if the dog see the bird fall, he will be very apt to break away, in which case he should be brought back to the spot whence he had run, and there making him lie down, call out, *down charge!* He should be compelled to remain in that position till the gun is reloaded; and the disposition and temper of the animal should be the rule and guide of correction. A well-bred dog will generally become perfect in this lesson in a very short period.

It sometimes happens that a young dog will testify every symptom of alarm on the firing of the fowling-piece:—will, per-

haps, run home, and be with difficulty brought again to the field. When this occurs, I consider it a very unfortunate circumstance, as it will frequently require no ordinary pains to free the dog from this unnecessary fear. There is no better mode of effectually remedying the evil, than by convincing the animal that the discharge of the fowling-piece is intended for a very different purpose than to create alarm. He must, therefore, be brought back, and compelled to remain in company with the sportsman: he must, in fact, be led in a cord, to prevent his running away again; and if an attendant be not in the field, the sportsman may tie the cord round his own body. A few birds should be killed over him as quickly as possible, which should be shewn to him, and he should be allowed to mouth them, if he appears inclined to do so: if a bird happen to be winged, he should be enticed to foot it:—thus he will very soon comprehend the true intention of the fowling-piece: his fears will subside; and he will shortly manifest as much anxious joyful expectation at the sight and sound of a gun, as he previously testified alarm and terror.

Some persons accustom their young dogs to the report of fire-arms at a much earlier period than when taken into the field; in fact, when they are very young. Certainly, if they endure the report of a gun or pistol at this early period, there can be little dread of their taking alarm when brought into the field: but if a very young dog or whelp takes fright on the report of a pistol or gun, his fears will become so rooted that much greater difficulty will arise in completing his education than in the case I have before stated. In fact, all firing of guns or pistols near him should be cautiously avoided, as a practice of this sort will but increase his alarm, unless, indeed, it were daily, and almost incessantly, resorted to. The dog must be regularly broke, and, when taken into the field with the fowling-piece, treated in the manner I have described above. It is highly important to convince the dog that the fowling-piece is for the purpose of killing the game, which he is to find; and this cannot be done when shooting merely to accustom him to the sound, as no object is thus placed before him. For the same reason I do not strongly recommend the practice of teaching dogs, when very young, to crouch in the lanes, &c. when you happen to be walking out, as the animal cannot be thus

aware of the ultimate intention of his master, or conscious of the object for which he is compelled to become prostrate: this method, in fact, teaches the dog to crouch too much, and, on that account, I never practise it, or, in other words, force my pointers to endure such abject and unmeaning servitude.

The best dogs may sometimes make mistakes—on bad scenting days, for instance; or if they happen to run down wind, particularly when it is blowing strong. On such occasions, it would be cruel to flog them, though the words expressive of caution may be used.

Well-bred pointers, as I have before observed, if taken into the field at a proper period, will, in general, require little breaking; they will often point and back of themselves, and, in fact, give the sportsman very great satisfaction with very little trouble.

The dog that first finds the game should always go up to it; and on no account should another be suffered to pass or run before him. It is like snatching his well earned reward, to say nothing of the confusion which must ensue from such a culpable practice.

A pointer or setter should never be named *Carlo*, *Sancho*, or, indeed, any other name ending in *o*, as the word *roho* is so frequently indispensable, and ending in the same sound, is apt to cause misunderstanding and confusion. A dog's name should consist of one expressive syllable, which comes forcibly from the mouth, such as *Bob*, for instance, and, where more than one dog is used, their names should sound as differently as possible.

It but too frequently happens that young dogs manifest an inclination to *hunt and worry sheep*, which must be instantly corrected. If a severe flogging have not the desired effect, the dog should either be tied to a strong ram, leaving a sufficient length of cord to allow the ram to make a run; or they should be confined together in a barn or some building. Flog the dog till he cries out, making use of the words '*ware sheep!*' The ram will not fail to commence a furious attack upon him, and will butt him most violently. They should be kept together for twenty minutes; the ram will not fail to continue his butting, and it may not be amiss to flog the dog several times during this period, making use of the words just mentioned at the same time. This will, most likely, prevent the dog ever looking

at sheep afterwards, unless, perhaps, where he has absolutely bitten them before this system of correction was put in practice, in which case, I am not aware of any mode of punishment or correction that can be depended on; for, although the dog may not even notice sheep in your presence, yet he will, nevertheless, be very apt to steal away, as opportunity may offer, for the purpose of depredation:—when once dogs have *tasted mutton*, they are never to be trusted. Indeed, I have seen an instance or two, where the dog, after having been a little butted, has fiercely turned upon the ram, which he would have torn to pieces had he not been prevented; but a circumstance of this sort rarely occurs, and, in the instances to which I allude, the dogs were grown rather too old to be cured by this or any other mode short of confinement or death. If a young dog look earnestly at, or *set*, a sheep, he should be corrected; and, if you find him repeat it, have recourse to the ram, as by far the most effectual mode that can be adopted. A dog should be corrected, in fact, the moment he is observed to manifest the slightest inclination even to notice sheep; as he will, if not checked, first look and set, then chase, and, ultimately, worry them.

As to poultry, the evil is not of so much magnitude, nor the disposition to worry it so difficult to subdue, as when sheep are the object; besides, poultry, by being generally about the house or premises, afford better, as well as more frequent, opportunities of observation. Young pointers are very apt to make their first essay, as it were, by worrying chickens, or pigeons, where

they happen to be very tame. Early and severe flogging will, however, generally remedy the evil: if not, tie a fowl (a living one is the best, on account of its fluttering) to the dog's tail, and tie it in such a manner, either by a cleft stick or otherwise, that it may give the dog considerable pain. Take him to a place some distance from his kennel, and, after giving him a few smart strokes with the whip, let him loose, and he will seldom fail to run home, howling all the way, (just as if a tin kettle were tied to him) and terrified beyond measure. He should, however, be followed, dragged from the farther end of his kennel, in which he will, no doubt, endeavour to hide himself, and be again well flogged; and the fowl, being taken from his tail, should be buffeted about his head.

I have met with sportsmen who teach their pointers to fetch the dead bird: I must confess I am not fond of this method, as the dog, thus accustomed to fetch the bird, is very apt to break away on the shot, whether a bird be killed or not.

**BREAKING DOWN.** This is an accident that often occurs during violent exertion, as in racing. It has been said to depend upon a rupture of the suspensory ligament of the leg; but the injury more commonly is, a severe strain of the sheath of the flexor tendon or back sinew. When the ligament is broken, it may be known by the increased obliquity of the pastern. The fetlock joint being bent nearly to the ground, the horse still has the power of moving the pastern, which could not be the case if the tendon were ruptured.

**BREAKING HORSES.** A well-known species of discipline exercised on colts, for the purpose of rendering them serviceable to man. There is a general want of well-qualified men in this way, as well as of good farriers. Our chance-medley breeders either break their horses themselves, or commit it to persons equally ignorant; whence the number of our *garoons*, the breed and education of which are so well matched.

The utmost care should be used to teach a colt his paces *distinctly*. You will observe numbers of horses, trained and ridden by little farmers and countrymen, which confuse and jumble the paces one into the other, shuffling between walk and trot, and trot and gallop, till they acquire a kind of rocking pace, from which it is no easy task to reclaim them: or they will, perhaps, go one pace only. If the colt be unfavourably made forward, and it appear from the mal-conformation of his neck, and the ill setting-on of his head, that he can never have a handsome carriage, double care must be taken to give him a well-

## B R E A M

tempered mouth, the only thing that can render a horse of this unfortunate description tolerable.

Such as show much blood, or stoop forward, and lounge in their gait, in the usual manner of bred cattle, ought to be well set upon their haunches.

The future goodness and value of the nag materially depend upon early tuition. If he be defective in bending his knees, let him be ridden daily in rough and stony roads; or, if that fail, cause him to be ridden every day, for a month or more, with blinds. Being blinded, he will naturally lift up his feet. I have experienced the use of it.

When a colt is refractory, it is usual to tame him, by riding him immoderately over deep earth. It is a silly custom, and often productive of great mischiefs, by weakening the tender joints of a young horse, breaking his spirit, or rendering it totally desperate. Coolness and perseverance are here the requisites: there is no horse with a stomach so proud, which a level course will not bring down.

The most proper period for breaking a saddle-colt, is the usual one, when *three years old*. In the common mode of performing this premier act of horsemanship, there is very little variation since Baret's days; or rather, it may be said, we have universally adopted his improved method. A head-stall is put upon the colt, and a cavesson over his nose, with reins. He is saddled, then led forth with a long rein, and, in due time, lounged, or led round a ring, upon some soft ground. As soon as he has become tolerably quiet, he is mounted, a proper mouth and carriage given, and his paces taught. When sufficiently instructed, he ought (in general) to be dismissed, until the following spring—an early period for serious business.

There are some who choose to defer breaking their colts until four years old, for which they often find just cause of repentance, in the strength and stubbornness of the horse: such practice would, however, be at least somewhat more safe, if a favourite method of mine were adopted, which is, to accustom colts to handling, to the halter, and the bitt, immediately upon their weaning.

**BREAKING THE DEER.** The term formerly used for cutting up the deer after the chase.

**BREAKING THE HERD.** The ceremony of singling out a deer from the herd for the chase.

**BREAM.** The bream is a very bony fish: they are not very numerous, either in the rivers Thames or Lea, but abound in the Trent, Wey, Byfleet, and the Mole, and several other rivers; also in Dagenham breach, and in the wet docks at Blackwall. They are frequently taken in the spring, during March, April, and May, when angling for carp with red worms. When angling for bream, use a gut line, long rod, quill float, and No. 9 hook, running tackle, and winch; ground bait with

new grains, or greaves, bran, and clay, made into balls, or chopped worms thrown in by handful. Let the baited hook drag half-an-inch on the ground in streams, and fish early in the morning and very late at night. Bream seldom bite in the middle of the day during summer months, unless it blows fresh, or warm rain descends; they then will take a bait freely all day, especially if the place has been well ground baited the night before. Two red worms put on the hook, or one well-scoured marsh-worm, is the best for bream: generally speaking, they will take gentles, and sometimes paste, and also wheat and malt, slightly baked or parboiled. When you angle for bream in a river, fish out further in the stream than when angling for roach;

and immediately you observe a bite, strike. If you are angling in quite still water, you may use two rods and lines, to which put small cork floats; cast the baited hook a good way in the water, having first plumbed the depth: the bait should hang just clear of the ground, that a gentle breeze may slowly move it; lay the rod over some rushes or sags; if there are none, choose a branch of a tree with a forked top close to the water, and let the rod rest on it; stand back, and wait patiently and quietly for a bite. By this method, where bream are plentiful, you may soon fill a basket; for they are a free-biting fish, and, though generally considered of little worth, yet they afford much amusement to the angler in bends and broad still parts of rivers, and not very deep places, where the bream like to resort.

The bream is a very broad fish, with scales somewhat like the carp, but lighter in colour, and, when large, are much like a bellows in shape; the head and mouth are small, large eye, and forked tail, which is of a dull purple colour, as also the fins: they will breed in still waters as well as in rivers, if the bottom is clay or loamy, as they prefer still or sluggish streams to large or rapid rivers: they spawn in May, and will grow to the weight of six pounds. Bream love such places as the carp and tench do in rivers; they will also take the same baits, and, like the carp, struggle hard, particularly when they first feel the hook; therefore, give him line freely before you attempt to turn him, if a heavy fish; for, like heavy barbel, they are often very sulky, and hang on the bottom for some time, then rush with violence under a bank, among weeds, &c.

There is a fish in the Broads (which are a larger piece of water so called in Norfolk,) much like the bream, which is known there by the name of bream-flats, dace, or red eye; it is a thicker fish than the bream, and somewhat hog-backed, like the perch, and the fins are red: this fish is generally covered with a slimy substance, and is altogether a very indifferent fish for the table: they are easily taken with worms, gentles, or paste.

BREECHES, }  
BREECHING. } See HARNESS.

BREEDING. See HORSE.

BREEDING DOGS. See POINTER, &c.

BRIDLE. See BIT.

BRIDLE HAND. The horseman's left hand.

BROCKELSBY BETTY, the property of Mr. Pelham, a Lincolnshire gentleman,

was deemed by many sportsmen the best mare ever bred in this country. She was got by the Curwen Bay Barb, out of the Hobby mare, by the Lister Turk, which horse was brought into England, by the Duke of Berwick, from the siege of Buda, in the reign of James II. In April, 1716, she beat a crack mare of the Duke of Devonshire, at Newmarket; in August, she won the gold cup at Black Hambleton. In April, 1717, the gold cup at Newmarket; in August, a silver tea-board at Lincoln; in October, a gold cup at York, and the king's plate at Newmarket. In April, 1718, the gold cup at Newmarket: in May she beat the Duke of Wharton's Snail, a match for 200 guineas, and the Duke of Bridgewater's Ashridge, a match for 900 guineas, which last horse was reckoned the best of his day. Brockelsby Betty was dam of a grey filly and a chesnut colt, both of which were named Brockelsby,—the former (1721) by Greyhound; the latter (1723) by Woodcock. In 1722 she missed to Woodcock. We are unacquainted with the time of her death.

**BROKEN KNEES.** When this accident is only slight, it will be sufficient to wash the horse's knees several times a day with a solution of sugar of lead—two ounces of the sugar of lead to two quarts of water. After using this for two or three days, the inflammation and swelling will subside. But if the knees are very badly broken, first wash them very carefully with warm water; then apply a poultice, and change it every morning and evening, till the inflammation and swelling of the knees have subsided; stimulating applications will then be proper, such as a solution of blue or white vitriol: when the wound does not heal under this treatment, use the following ointment:—

Ointment of yellow rosin, 4 ounces.  
Oil of turpentine, 2 drachms.  
Red precipitate in fine powder, 3 drachms.

If the new flesh should rise higher than the surface, sprinkle it over with burnt alum finely powdered. Some men have a wonderful facility in breaking the knees of their horses; nothing contributes so much to it, as riding with the reins always tight: this punishes the horse unnecessarily, and makes him careless of his steps, and he will come down much sooner than if he was ridden with an easy rein. If a man gets on to horseback, and is afraid the horse will come down with him, he is almost sure to do so. Neatsfoot, or any animal oil, is an admirable application for reproducing hair on a broken knee.

**BROKEN WIND.** It seems that those who first named this disease were well acquainted with its nature. It has been called broken wind time out of mind, and it is in reality a broken lung; and it may be defined to be a rupture of the membrane connecting the air-cells of the lungs together: it is so striking, that the person who has once seen it cannot afterwards mistake it. In this disease, the respiration of the animal is laborious, and apparently more affected than in any other to which he is subject. Both the inspiration and expiration of the horse, when in health, we find to be uniformly of the same length; but the horse labouring under this disease has the expiration very long, and the inspiration very short, which may be well seen by observing the flanks of the animal, for the muscles are a long time in drawing themselves up, and forcing the air out of the lungs; but they very readily fall, and allow the admission of the air into the lungs. The lungs of these diseased animals are specifically lighter than healthy lungs. The disease is brought on by violent exertion during the time that the stomach is much loaded, and particularly with water; and when this is the case, the abdominal muscles and diaphragm cannot act in respiration, which distresses the animal to the utmost degree, more particularly if exercised; for the horse is the only animal we can compel to exertion, when distressed by it. After eating, you may observe that the dog will refuse to hunt. It is inconsistent with the health of the horse, to offer him as much food of any kind as he can eat; for however full he may be, he is always hungry, and willing to devour more, which passes off almost as fast as it is taken in. This disease is much more frequently produced by some kinds of food than others, depending, as we shall find, upon its bulk. In the cavalry, when hay is cheaper than oats, we find this disease very common; but when the reverse happens, and oats are cheaper than hay, it is very rare, for the food, not being so bulky, does not distend the stomach and colon so much as in the other instance. We see very little of this disease in post and mail-horses, and the reason is obvious; no horses are better fed than these horses; none are in better condition, or can do more work; they have as much corn as they can eat, which is nearly half-a-bushel; they are allowed only about five pounds of hay per day, and that is best given after labour, or in the night.

Again, the post-horse never has his allowance of water till he has entirely finished his work; and we always observe that these animals go very fleetly, and perform long journeys, without a fault. A broken-winded horse can scarcely be heard to cough; when he does, it is a mere effort, as he has not the power of forcing the air from his lungs, and making the shrill noise which a sound horse makes when coughing. The mode of ascertaining this disease, when the horse stands still, is to pinch his windpipe with the finger and thumb; this produces cough which takes place in health; but it is so faint in this disease, as hardly to be heard across the stable, and is what the dealers call an inward cough; and whoever has once heard it will never mistake it. Medicine cannot possibly do good in this disease; regimen is the only means we can place any confidence in; and, by proper regimen, a horse so affected will do a vast deal of work, and do it well. It would be proper, after he has had his allowance of oats, to muzzle him, to prevent him eating his litter during the night, which he will do without such precaution.

**BROOK-HAWKING** is a sport which is managed with the gerfalcon and jerkin, the haggard, and the tiercel gentle.

There are in many places ponds inclosed with woods, bushes, and the like obscurities, so that they are concealed from passengers; and to such places wild ducks very much resort.

To train up a hawk for this kind of diversion, the following are the directions:

The hawk being in all points ready to fly, a trained duck should be provided; and a man should lie concealed in some bush by the pond with them; so that when you come to the place, and the hawk is ready for the sudden flight, beat the bush where the man lies concealed with the duck, when he must let it fly; when, if the hawk take it with courage, reward her well.

The hawk being trained to this, you may confidently go with her to the ponds where the fowls are to be found; and, creeping as close as possible to the place, raise them by beating about with a pole: when they rise, let go the hawk; and if she seize, let her enjoy it, and be well rewarded.

**BROW ANTLE.** That branch of a deer's horn next the head.

**BRUISES.** When a horse has got severely bruised, bleed, and give him a purgative; and either foment the part, or

apply a poultice. Should matter form, it is to be treated as an abscess. If any hard swelling remains, attempt to disperse it by rubbing it well with some stimulating liniment, as the following:—

Soap liniment, 4 ounces.

Liquid ammonia, 1 ounce.—Mix.

Should this fail, you must have recourse to a blister.

BRUSH. The tail of a fox.

BUCK. The male of the fallow deer. In his first year he is called a fawn; the second, a pricket; the third, a sorrel; the fourth, a sove; the fifth, a buck of the first

head; the sixth, a great buck. In colour they are mottled, sandy, or a deep dingy brown.

BUCK-HUNTING has been of late years but little practised: for the chase the buck is not equal to the stag, though he is pursued in the same manner: he is neither so strong nor so swift as the stag, and therefore seldom stands up long before the hounds. See STAG.

BUCK-STALL. A kind of large net, called also a DEER-HAY, for taking deer. See NET.

**BUFFALO.** This animal, in its general form, has a great resemblance to the common ox, but it differs from it in its horns, and in some particulars of its internal structure. It is larger than the ox; the head is also bigger in proportion, the forehead higher, and the muzzle longer. The horns are large and of a compressed form, with the exterior edge sharp: they are straight for a considerable length from their base, and then bend slightly upwards. The general colour of the animal is blackish, except the forehead and the tip of the tail, which are of a dusky white. The hunch is not, as many have supposed it, a large fleshy lump, but is occasioned by the bones that form the withers being continued to a much greater length than in any other animal.

Buffaloes are natives of the warmer parts of India and Africa, but have been introduced into some of the countries of Europe, where they are now become naturalized. In Italy they are perfectly domesticated, and constitute an essential part both of the riches and food of the poor. They are there employed in agriculture; and butter and cheese are made from their milk. These animals are very common in western Hindostan. They are fond of wallowing in the mud, and will swim over the broadest rivers. During inundations they are frequently observed to dive ten or twelve feet deep, to force up with their horns the aquatic plants, which they eat while swimming.

In many parts of the East, as well as in Italy, buffaloes are domesticated. It is said to be a singular sight to see, morning and evening, large herds of them cross the Tigris and Euphrates. They proceed all wedged against each other, the herdsman riding on one of them, sometimes standing upright, and sometimes crouching down; and, if any of the exterior ones are out of order, stepping lightly from back to back, to drive them along.

The buffalo met with in Africa is an animal of a very savage disposition. It is very large and uncommonly strong, and is frequently seen in herds in the neighbourhood of the Cape. The fore parts of the body are covered with long, coarse, and black hair. The horns are thick and rugged at the base, sometimes measuring three feet in length, and lying so flat as to cover almost all the top of the head.—The ears are large and slouching. The body and limbs are very

## B U F F A L O

thick and muscular; and the animal is above eight feet long and six in height. The head hangs down, and bears a most fierce and malevolent aspect.

In the plains of Caffraria, buffaloes are so common, that it is by no means unusual to see one hundred and fifty or two hundred of them in a herd. They generally retire into the thickets and woods in the day time, and at night go out to graze. Treacherous in the extreme, they frequently conceal themselves among the trees, and there stand lurking till some unfortunate passenger comes by, when the animal at once rushes out into the road and attacks the traveller, who has no chance to escape but by climbing up a tree, if he is fortunate enough to be near one. Flight is of no avail, he is speedily overtaken by the furious beast, who, not contented with throwing him down, and killing him, stands over him even for a long time afterwards, trampling him with his hoofs and crushing him with his knees; and not only mangles and tears the body to pieces with his horns and teeth, but likewise strips off the skin by licking it with his tongue. Nor does he perform all this at once, but often retires to some distance from the body, and returns with savage ferocity, to gratify afresh his cruel inclination.

As Professor Thunberg was travelling in Caffraria, he and his companions had just entered a wood, when they discovered a large old male buffalo lying quite alone, in a spot that, for a few square yards, was quite free from bushes. The animal no sooner observed the guide, who went first, than, with a horrible roar, he rushed upon him. The fellow turned his horse short round behind a large tree, and the buffalo rushed straight forward to the next man, and gored his horse so dreadfully in the belly, that it died soon after. These two climbed into trees, and the furious animal made his way towards the rest, of whom the Professor was one, who were approaching, but at some distance. A horse without a rider was in the front; as soon as the buffalo saw him, he became more outrageous than before, and attacked him with such fury, that he not only drove his horns into the horse's breast, but even out again through the very saddle. The horse was thrown to the ground with such excessive violence that he instantly died, and many of his bones were broken. Just at this moment the Professor happened to come up, but from the narrowness of the path, having no room to turn round, he was glad to abandon his horse, and take refuge in a tolerably high tree. The buffalo, however, had finished; for, after the destruction of the second horse, he turned suddenly round and galloped away.

Some time after this, the Professor and his party espied an extremely large herd of buffaloes grazing on a plain. Being now sufficiently apprised of the disposition of these animals, and knowing they would not attack any person in the open plains, they approached within forty paces, and fired amongst them. The whole troop, notwithstanding the individual intrepidity of the animals, surprised by the sudden flash, and report, turned about and made off towards the woods. The wounded buffaloes separated from the rest of the herd,

## B U F F A L O

from their inability to keep pace with them. Amongst them was an old bull buffalo, which ran with fury towards the party. They knew that, from the situation of the eyes of these animals, they could see in scarcely any other direction than straight forward; and that in an open plain, if a man that was pursued, darted out of the course, and threw himself flat on the ground, they would gallop forward to a considerable distance before they missed him. These circumstances prevented their suffering any material alarm. The animal, from this contrivance, passed close by them, and fell before he appeared to have discovered his error. Such, however, was his strength, that, notwithstanding the ball had entered his chest, and penetrated through the greater part of his body, he ran at full speed several hundred paces before he fell.

The Cape buffalo is frequently hunted both by Europeans and the natives of South Africa. In Caffraria, he is generally killed by means of javelins, which the inhabitants use with considerable dexterity. When a Caffre has discovered the place where several buffaloes are collected together, he blows a pipe, made of the thigh bone of a sheep, which is heard at a great distance. The moment his comrades hear this notice they run up to the spot, and, surrounding the animals, which they take care to approach by degrees, lest they should alarm them, throw their javelins at them. This is generally done with so sure an aim, that out of eight or twelve, it is very rarely that a single one escapes. It sometimes happens, however, that, while the buffaloes are running off, some one of the hunters who stands in the way, is tossed and killed; but this is a circumstance not much regarded by the Caffres. When the chase is ended, each one cuts off and takes away his share of the game.

Some Europeans at the Cape once chased a buffalo, and having driven him into a narrow place, he turned round, and instantly pushed at one of his pursuers, who had on a red waistcoat. The man, to save his life, ran to the water, plunged in, and swam off: the animal followed him so closely, that the poor fellow had no alternative but that of diving. He dipped overhead, and the buffalo, losing sight of him, swam on towards the opposite shore, three miles distant, and, as was supposed, would have reached it, had he not been shot by a gun from a ship, at a little distance.

Like the hog, this animal is fond of wallowing in the mire. His flesh is lean, but juicy, and of a high flavour. His hide is so thick and so tough, that targets, musket proof, are made of it; and even while the animal is alive, it is said to be in many parts impenetrable to a leaden musket ball: balls hardened with a mixture of tin, are therefore, always used, and even these are often flattened by the resistance. Of the skin, the strongest and best thongs for harness are made. The Hottentots, who never put themselves to any great trouble in dressing their victuals, cut the buffalo's flesh into slices, and then smoke and at the same time half broil it, over a few coals. They also frequently eat it in a state of putrefaction.

The American Bison is an animal of the same species, and has

## B U F F A L O

short rounded horns, pointing outwards ; it is covered in many parts with long shaggy hair, and has a high protuberance on the shoulders. The fore parts of the body are excessively thick and strong, and the hinder parts are comparatively very slender.

These animals range in droves, feeding in the open savannahs, morning and evening. They retire, during the sultry parts of the day, to rest near shady rivulets and streams of water, frequently leaving so deep an impression of their feet in the moist sand (from the great weight of their bodies) as to be thus traced and shot by the artful Indians. In this undertaking it is necessary that the man should be particularly careful, since, when only wounded, the animals become excessively furious. The hunters go against the wind, as the faculty of smell in the bisons is so exquisite, that the moment they get scent of their enemy, they retire with the utmost precipitation. With a favourable wind, the men approach very near, since the animals are frequently almost blinded by the hair that covers their eyes. In taking aim, they direct their piece to the hollow of the shoulder, by which means they generally bring them down at one shot. If they do not fall, they immediately run upon their enemy, and, with their horns and hoofs, tear him to pieces and trample him into the earth.

They are so amazingly strong, that when they fly through the woods from a pursuer, they frequently brush down trees as thick as a man's arm; and, be the snow ever so deep, such is their strength and agility, that they are able to plunge through it much faster than the swiftest Indian can run in snow shoes. " To this (says Mr. Hearne,) I have been an eye witness many times, and once had the vanity to think that I could have kept pace with them; but though I was at that time celebrated for being particularly fleet in snow shoes, I soon found that I was no match for the bisons, notwithstanding they were then plunging through such deep snow, that their bellies made a track in it as large as if many heavy sacks had been hauled through it.

In Canada, hunting the bison is a very common employment of the natives. They draw up in a large square, and commence their operations by setting fire to the grass, which, at certain seasons, is very long and dry. As the fire goes on, they advance, closing their ranks as they proceed. The animals, alarmed by the light, gallop confusedly about, till they are hemmed in so close that frequently not a single beast escapes.

In Louisiana, the men mount on horseback, each with a sharp crescent-pointed spear in his hand. They approach with the wind, and as soon as the animals smell them, they instantly make off; but the sight of the horses moderates their fear, and the majority of them, from their luxuriant feeding, are, at certain times of the year, so fat and unwieldy, as easily to be enticed to slacken their pace. As soon as the men overtake them, they endeavour to strike the crescent just above the ham, in such manner as to cut through the tendons, and thus render them an easy prey.

## BULL BAITING

The hunting of these animals is also common in several parts of South America. It commences in a sort of festivity, and ends in an entertainment, in which one of their carcasses supplies the only ingredient. As soon as a herd of cattle is seen on the plain, the most fleet and active of the horsemen prepares to pursue them; and, descending in the form of a widely extended crescent, hunt them in all directions. After a time they become so jaded and weary, that they seem ready to sink under their fatigue; but, the hunters, still urging them to flight by their loud cries, drive them at last from the field.—Such as are unable to exert the necessary speed for escape, are slaughtered. The hunters, from these, supply themselves with what flesh they want, and abandon the rest to the wolves.

The sagacity which the bisons exhibit in defending themselves from the attacks of the wolves, is admirable. When they scent the approach of a drove of those ravenous creatures, the herd throws itself into the form of a circle, having the weakest in the middle, and the strongest ranged on the outside; thus presenting an impenetrable front of horns. When, however, they are taken by surprise, and have recourse to flight, numbers of those that are fattest and most weak must infallibly perish.

**BUGLE HORN.** The horn formerly used by huntsmen was called a bugle horn; this was when stag hunting was common all over the kingdom; various sounds or airs were then employed in the chase, which have since been abandoned. In fact, stag hunting is at present but little pursued: it has been superseded by the chase of the fox, and the straight horn

generally adopted in preference to the bugle; at all events, the horn now employed in the chase, is merely to call the hounds round the huntsman, if we except the ceremonies used on turning out a royal deer. The horn is used both with fox hounds and harriers, merely in the way in which we have just described it.

**BULL BAITING** was formerly a very popular amusement in this country; it was frequently attended by noblemen of the first distinction; and even royalty itself occasionally honoured the bull ring with its presence. The method of baiting a bull is the following:—the animal is fastened to a stake driven into the ground for the purpose, and about seven or eight yards of rope left loose, so as to allow him sufficient liberty for the fight. In this situation a bulldog is slipped at him, and endeavours to seize him by the nose; if the bull be well practised at the business, he will receive the dog on his horns, throw him off, and sometimes kill him; but, on the contrary, if the bull is not very dexterous, the dog will not only seize him by the nose, but will cling to his hold till the bull stands still; and this is termed *pinning the bull*. What are called good *game bulls* are very difficult to be pinned: animals of this description are constantly on their guard, and, placing their noses close to the ground, they receive their antagonist on their horns; and it is astonishing to what distances they will sometimes throw him. It is not deemed fair to slip or let loose more than one dog at one and the same time.

The first bull-baiting, well authenticated to have taken place, was during the reign of King John, in 1209, at Stamford in Lincolnshire,

## BULL BAITING

and originated in the following circumstance:—William, Earl Warren, Lord of Stamford, standing upon the walls of the castle, observed two bulls fighting for a cow in the castle meadow, till all the butchers' dogs pursued one of the bulls (maddened with noise and multitude) entirely through the town. This sight so pleased the Earl, that he gave the castle meadow, where the bulls' combat began, for a common, to the butchers of the town, after the first grass was mown, on condition that they should find "a mad bull," the day six weeks before Christmas day, for the continuance of "that sport for ever."

A similar institution, under the appellation of bull-running, was established at Tutbury, in Staffordshire, about the year 1374, where, by the custom of the manor, a bull was given by the prior to his minstrels. After having his horns cut off, and his body besmeared with soap, he was turned out to be hunted by the multitude; and when taken or obstructed long enough to pull off some hair, he was chained to the stake to be baited by dogs. This custom was abolished in 1778.

One George Staverton, by will, bearing date May 15, 1661, gave the whole of his dwelling house, situated at Staines, in Middlesex, (after two lives) to purchase a bull annually for ever; which bull he gave to the poor of the town of Workington, in Berkshire, to be there baited, then killed, and equitably divided; the offal, hide, and gift-money (collected from the spectators) to be laid out in shoes and stockings, to be distributed among the children of the poor. The chief alderman, and one Staverton (if one of the name should be living in the town or neighbourhood) to see the work truly and justly performed, that "one of the poor's piece did not exceed another's in bigness." In the town of Workington, St. Thomas's day was annually dedicated to the sport, and the public market-place the spot invariably appropriated for it.

James I. was much attached to the diversion of bull-baiting; and, amongst other places for the enjoyment of his favourite sport, he was in the habit of visiting Coleorton, in Leicestershire. Coleorton is a very large, but straggling village, about three miles from Ashby de la Zouch, and, for a century or two, famous for its coal mines. The miners or colliers, were passionately fond of the sport in question, which, perhaps, received an additional zest from the visits of the monarch. Bull baiting was carried on with unabated vigour at this place, from the time we have just mentioned; and about thirty years ago, was as popular as ever; of which the writer (then a school-boy) at the period just mentioned, was frequently an eye witness. Shortly after this, bull baiting declined, in some degree, from magisterial influence, but much more from the decline of what may be called the trade of the place: the coal mines became exhausted, and the miners were consequently under the necessity of seeking employment elsewhere. They removed principally to the Potteries, in Staffordshire, where there was plenty of coals; and where, from the increase of the earthenware business, an increase of coal miners was

indispensable. These miners carried their customs and amusements from Coleorton, in Leicestershire, to the Potteries, in Staffordshire, and bull, as well as bear, baiting continued to flourish. On the establishment of peace, the trade of this part of the country declined, and bull baiting declined also: it has not yet been altogether abandoned.

About two centuries ago, bull baiting was common all over the kingdom; it has gradually declined; though in some market and other towns, the bull-ring is pointed out, and the very stake to which the bull was fastened is still in existence.

**BULL-DOG.** The English bull-dog is uniformly allowed to possess the most undaunted and the most persevering courage of the whole dog tribe; but the breed is said to degenerate if removed to any other country. There is something uncouth and forbidding in the appearance of this animal: the short head, the ferocious underhung jaw, the distension of the nostrils, and the constant sight of the teeth, give it an appearance at once unsightly and terrific.

As the bull-dog differs in appearance from all other dogs, so his temper and disposition seem equally removed from the general standard. It is a well-known fact, that dogs are creatures of a most forgiving disposition, and far more mindful of benefits received than of injuries sustained; but the bull-dog offers, in a great degree, the reverse of this portrait, and appears seldom, if ever, to forget or forgive any serious insult which has been offered to it. Many incontestible instances might be given of the bull-dog's implacable resentment; but perhaps the following will be regarded as sufficient: Mr. Richard Wright, a gentleman who resided in Ormskirk (Lancashire) for many years, and who died about the year 1806, had two well-bred animals of this kind, (dog and bitch) with which he was in the habit of the greatest familiarity; from some circumstance, however, he chastised one of them rather severely, which the animal did not resent at the time; but, as Mr. Wright sometimes introduced them into the parlour, for the purpose of caressing them, on one of these occasions, the animal which he had formerly chastised seized him by the neck, and clung to its hold with the most obstinate perseverance, till it was killed.

It is very well known, that the bull-dog is capable of maintaining his hold with incredible perseverance; this, of course, arises, in a great degree, from his courage; but this alone would not be sufficient

for the purpose: it will be found, on examination, that he is peculiarly formed for this purpose; and by the protrusion of the nether jaw, and the consequent recession, as it were, of the nose, the animal is enabled to breathe with tolerable freedom, even while his jaws are fastened to the object.

It is an invariable characteristic of the true-bred bull-dog to attack in front, and never to make a cowardly attempt at the extremities. The true-bred dog, the moment he is slipped, makes for the face of the bull with the most ungovernable fury, and will not fail to fasten on the bull's nose, unless he is prevented by the animal's horns. But the breed of bull-dogs is not so numerous, nor yet so nicely attended to, as formerly, and perhaps, at no distant period, will be altogether extinct—"a consummation devoutly to be wished;" as they are calculated for no one useful purpose. Possessing, in a very high degree, the quality of courage, they are, at the same time, the worst calculated of all other dogs for the purpose of protecting the house from nocturnal depredation: except when excited to run at the bull, the bear, &c. they are very sluggish and inactive; and thieves might very probably break into a house, and even murder the family, and the bull-dog continue his repose with indifference. Further, when they make an attack, it is in silence; and were they to seize an innocent person, or a child, the most disastrous consequences, or death itself, might result: supposing the victim to be disabled from screaming, the mischief would proceed in silence, and the catastrophe take place without any person being aware of the circumstance.

**BULL FIGHT.** An amusement still prevalent in Spain, though much more so in former times than at present. The following description of a bull fight, as *now* practised in Spain, is taken from the *Morning Herald*, for which it was written

by a gentleman who went to Madrid for the express purpose of communicating information on Spanish affairs, and who was an eye-witness of the bull-fight which took place in that metropolis on Sunday, the 12th of January, 1823, and which he thus describes:—

From political subjects of such importance as now agitate this fine country, and the noble inhabitants of Spain, who are poor in every thing but *courage*, I scarcely know how to make a transition, with any grace, to a *bull fight*. But a traveller has many matters placed under his observation which have no affinity with each other, and he must submit to take them as they come. My prejudice against these exhibitions was very decided, and it was some time before I could prevail upon myself to attend one of them. There is, however, no resisting example; and when, on Sunday last, (intercede for my pardon with the moral readers of the Herald,) I saw crowds of people, men, women, and boys, hastening to the amphitheatre, I could not avoid following in their train. The amphitheatre is a vast circular building, immediately beyond the precincts of the capital, about a hundred yards from the gate called La Puerta de Alcala; it is capable of accommodating from *ten to fourteen thousand persons*; and I cannot afford a clearer idea of its structure, than by desiring you to imagine an extensive circular arena, which is defended by a high and strong wooden partition, that runs all round, and has four gates at the four points of the compass. One of these is used for the entry of the master of the games, or the director; another, for the entry of the bulls; another, for the egress of those bulls which are not killed; and the last, for affording a passage to the horses which drag out the bulls that are slain. Between the wooden boundary of the arena, and that which encloses the lower gallery for the spectators, there is an open space that runs all round, in order that, if the bulls should at any time overleap the boundary, they may be driven back again to the arena through this space, one of the gates being opened. They are thus prevented from doing injury to the spectators. The lower gallery runs all round, sloping towards the arena, and, as well as the arena, is exposed to the open air. The second gallery, which is immediately over this, is covered by the boxes; and the boxes, which are very high, are protected from the sun and sudden rain by a narrow roof of tiles, which does not project beyond

them. Fifty reals are paid for the use of a whole box, four for the second gallery, and two for the lower. At three o'clock the amphitheatre began to fill rapidly; and it was easy to perceive, from the expectation painted in the countenance of the visitors, as they came in and seated themselves, that the bull fight is a favourite amusement. It was new to a stranger to hear the members of different parties calling out to each other, in order to arrange themselves with the greatest convenience, by such names as Barbara, Margarita, Nicolassa, Maria, Herminia, Olimpia, Pedro, Innocentio, Francisco, and others of similar terminations. The women and young girls, as usual, were all in their hair, covered, the better sort with black lace veils, and those of the less affluent classes with a black silk veil, edged with lace. Most of them had also fans, which the Spanish women use not only to refresh themselves in warm weather, but to guard their eyes from the sun, who generally looks down upon this favoured land, without a cloud to impair his brilliancy.

The director, dressed in the ancient Spanish style, with a short black mantle, a hat turned up at the sides, and on the left side a plume of white and red feathers, rode into the arena upon a handsome charger shortly after three o'clock, and, after bowing to the alcala, who presided, and sat in the box on the right of the king's box, gave order for the entertainment to commence. Two horses immediately appeared in the arena, each laden with two riders, who were seated on a pad back to back. The hindmost kept his place, by holding in his left hand a cord attached to the pad, and in his right he carried a long wooden staff, pointed at the end, for the purpose of beating away the bull that was about to attack him. A bull was then let into the arena; the tips of his horns were made harmless, by being covered with lead. As soon as he saw the horsemen, he proceeded directly against one of them; and the combatants, being apparently new to the office, offering no effectual resistance, he butted his horns beneath the horse's tail, and overthrew both horse and riders. He then attacked the other with equal success; when the riders were unhorsed, the bull seemed contented with his victory, and this contest was continued for some time with alternate success, the bull, however, being most frequently the conqueror, to the great amusement of the spectators.

A military band which attended having given a flourish of trumpets, this bull retired. Two skilful horsemen, handsomely dressed in white and red silk jackets, covered with gold lace, and in white hats, with a large round leaf, and a low arched crown, entered. They carried also each a long staff, with an iron spike at the end of it. A bull was then let in, whose horns were in their natural condition; and as soon as he fixed his wild-looking eyes on the riders, he proceeded to attack one of them. These, however, being well exercised, fought him away generally; but the contest being attended with some danger both to the horse and the rider, it excited strong interest. One of them was thrown to the ground, together with the horse; but happening to be near the partition of the arena, some of the spectators stretched over the partition to his assistance, and delivered him from the rage of the ferocious animal. When the horsemen had wearied him in some degree, three or four pedestrians teased him a little in turn. They carried in one hand a scarf of yellow or red silk; and, after approaching him, they ran towards the boundary with all speed, trailing the scarf behind; and if they were in danger of being overtaken, they let the scarf fall on the ground. The bull immediately stopped, and vented all his rage upon this scarf, as if under belief that it covered his adversary, while the fugitive had time to leap over the boundary. After this, the animal being pretty well fatigued, the same pedestrians, who were also handsomely dressed, armed themselves with strong iron darts, as it was the object of each to run upon the bull with agility, and, just as he was in the act of stooping his head to toss them, to fix two of these darts, one at each side of the back of his neck. Being bearded, it was with great difficulty the animal could get rid of them, and sometimes he was seen raging round the arena, his neck bristled with these torturing instruments. At length, when he was almost exhausted, an expert performer approached the animal, holding a red mantle before him in one hand, and with the other he thrust a long sword in beneath the shoulder.

The bull now fell, and another attendant came with a knife, and, fixing it in the vital part of his head, put an end to his agonies. He was then dragged along the arena by three horses, and carried away. Two bulls were killed in this manner: the second was an immensely strong one, and he leaped after one of the at-

tendants twice over the boundary; but, from the arrangement already mentioned, he was driven into the arena again without doing any mischief. A third bull was killed in the following barbarous way: A green fir-tree was planted opposite the gate at which the bulls enter; and before this tree, a man covered with a kind of armour of oiled canvas, and having a false head of a monster with the mouth open, knelt on one knee; and a strong wooden pole, with a large flat steel point, keenly sharpened, was given to him; and, fixing one extremity of it in the ground, he sloped the point so as to meet the bull on rushing in at the gate. Being so fixed, the gate was opened, and a wild bull immediately rushed in upon him with such amazing force, that the spear penetrated completely through, and came out at the back. Still the animal was not mortally wounded; he attacked his adversary, who, pretending to be dead, permitted himself to be rolled about by the animal; and the bull, seeing the thing before him apparently shapeless and void of life, soon left it, and ran infuriated over the arena, the spear still remaining in his side, for it passed immediately under the ribs to the back. It was a shocking exhibition; but still so strong was the animal, that the attendants could not get near enough, without danger, to kill him, until, by means of a curved knife attached to a long pole, they cut the ham-strings. Even after this, he made efforts to move, but at last he fell, and his agonies were terminated. Here ended what might be called a second part.

The third part was of a more innocent, and also of a more useful character. Five or six bulls, whose horns were leaded, were let in successively into the arena, and the younger classes of the spectators crowded to emulate each other in worrying the animals. By holding their cloaks before them, or one of those gay silk or worsted scarfs which many of the Spaniards wear under the vest round the waist, they induced the bull to run after them. If he were too quick upon them, they threw down the cloak or scarf, and leaped the boundary. But frequently they could not run fast enough, and the bull threw them down. His attention being immediately drawn off to another adversary, no harm ensued. One lad, however, in endeavouring to escape, fell down; the bull was instantly upon him, and raised him aloft upon one of his horns, as if he was a fly. The lad, with great

presence of mind, finding himself riding on the horn, caught hold of the end of it, and was thus carried about the arena to the infinite amusement of the spectators; fortunately, he was tossed off again without any further injury than a rent in his trousers. In this part of the entertainment it is that the national utility, and perhaps the moral justification of these exhibitions, consists; for it serves to accustom them to danger, to render them active and dexterous, and, in some measure, to prepare them, by these mimic combats, for contests of a more important description. The whole concluded with a display of fire-works, which were upon a narrow scale. There were about five or six thousand present. I must add, that this exhibition, which I have described, was one of rather the middling order. The best shows are in summer time. But, such as it was, it was considered the best to have been given this winter. There is a similar one every Sunday that the weather permits, which does not occur very often, as the winters in Madrid are severe.

Such is the bull fight, as still practised in Spain, scarcely differing from what has been practised in that country for some centuries past.

We learn from the entertaining letters of Don Leucadio Doblado, that at Seville, about the beginning of summer, the great breeders of black cattle, generally men of rank and fortune, send an invitation to their neighbours to be present at the trial of the yearlings, in order to select those that are to be reserved for the amphitheatre. The greatest festivity prevails at these meetings. A temporary scaffolding is erected round a very large court, for the accommodation of the ladies, and the gentlemen attend on horseback in peculiar dresses adopted on this occasion.

Each of these cavaliers holds a lance twelve feet in length, headed with a three-edged steel point. This weapon is called *garrocha*, and it is used by horsemen whenever they have to contend with bulls, either in the fields or amphitheatre. The steel, however, is sheathed with two strong leather rings, which are taken off in proportion to the strength of the bull, and the sort of wound which is intended. On the present occasion, no more than half-an-inch of steel is uncovered; double that length is allowed in the amphitheatre, though the spear is not intended to kill or disable the animal, but to keep him off by the painful pressure of the steel on a superficial wound.

The company being assembled in and round the rural arena, the one year old bulls are singly let in by the herdsman.—It might be supposed that animals so young might be frightened at the approach of the horseman couching his spear before his eyes, but the Andalusian breeders expect better things from their favourites. A young bull must attack the horseman twice, bearing the point of the spear on his neck, before he is set apart for the bloody honours of the amphitheatre.—Such as flinch from the trial, are instantly thrown down by the herdsmen, and prepared for the yoke on the spot.

BURROWS are the holes which rabbits make in the earth: anciently called Clapers.

BUSTARD (LITTLE), is about seventeen inches long: its plumage on the back, wings, neck, throat, and tail, is beautifully streaked, barred, and freckled with pale and dark brown; the belly and vent are white, with a few black spots.—This bird is very rare in England, though in France it is very common. Bewick observes, that “it is a very shy and cunning bird; if disturbed, it flies two or three hundred paces, not far from the ground, and then runs away much faster than any one can follow on foot. The female lays her eggs in May, to the number of three or four, of a glossy green colour; as soon as the young are hatched, she leads them about as a hen does her chickens; they begin to fly about the middle of August.

In former times, when the waste lands were in greater plenty, and more extensive, the plains and downs of England abounded with the bustard, the most magnificent of feathered game; being by far the greatest land-bird which Great Britain possessed. At present the race is diminishing very fast, if it be not altogether extinct.

The colour of the large bustard on the neck, back, and tail, is of a pale yellow or fawn colour, beautifully varied with black; the throat, belly, and thighs, are white; and from each cheek springs a tuft of white hairy feathers, like a pair of mustachios, which gives it a very singular appearance: its shape is very much like a turkey, of which it may be considered a species; its form is however lighter and taller. The weight of the cock sometimes amounts to thirty pounds, whilst that of the hen is one-third less. Bustards, though extremely swift of foot, fly so very badly, and are so long in taking wing, that it is said, they

were successfully coursed in England, when they were more plentiful, with greyhounds, being overtaken by the dogs before they could commence their flight. The female lays her eggs, which are larger than those of a turkey, of a greenish colour, spotted with brown, and never more than six in number, on the bare ground, in a hole which she scratches for the purpose; and if they are touched or soiled during her occasional absence, she immediately abandons them. The male, as well as by his size, is also distinguished from the female, by a large pouch, beginning under the tongue and reaching to the breast, capable of containing nearly a quart of water. This is useful to the female during incubation, and also to the young before they quit the nest; and it has been observed to be advantageous to the male bird itself, for, on its being attacked by birds of prey, it often discomfits its enemy by the sudden and violent discharge of water upon them.

With regard to shooting bustards, when you can find them, Colonel Hawker observes, that as these birds will occasionally suffer carts and carriages to come very near them, they have frequently been shot by using this method of approach. Inhabiting places frequented by shepherds, they may also be approached by the sportsman's carrying a hurdle to conceal his gun.

It is much to be lamented that so noble a bird should be suffered to become extinct, as we doubt not they soon will be, without an attempt being made to domesticate them. Breeding stock might readily be brought from the continent, in many parts of which they are said to abound, particularly Hungary. Neither ought the circumstance of their laying such a small number of eggs deter any one who might wish to make the attempt, as the fecundity of birds is, without one exception, increased by domestication.

**BUTTONS**, the excrements of a hare or rabbit.

**BUYING HORSES.** Having already been made acquainted with the terms, and that the nag is quiet to approach, giving him some gentle warning with your voice, you go up to him in his stall on the near side, and laying your hand on his fore-hand, you proceed from thence to examine his eyes, mouth, and countenance; still holding his head, and turning your own to the right about, you have a view of the curve of his neck, the height of his fore-hand, and the position of his shoulder and fore-

arm. Returning to his fore-hand, you descend to his legs and feet, minutely examining with your fingers every part from above, below, withinside, and without. You will not forget the virgin integrity of the knees, so much and so justly in request. So difficult is this to repair, either by nature or art, when once violated, that I am almost tempted to add to it as a fifth, to the four irrevocable thing, *tempus, juven-tus, verbum dictum, et virginitas*.

Being satisfied respecting his fore train, your eye and hand will glance over his back, girthing-place, carcase and loin; thence proceeding to his hinder quarter, and the setting-on of his tail. You will judge how far he agrees in each, and every respect, with the rules of proportion. The hinder legs and feet will demand a share of attention full as minute as the fore ones, and I must once again repeat my advice, that the inside, or hollow of the hock, be not passed without due notice (as is commonly the case) since it often happens that the injuries of hard labour are most apparent in those parts. A survey of the other side of the horse concludes the stable examination.

Suffer no person belonging to the seller to be with you in the stall during your inspection, that the horse may not be rendered unquiet, either designedly, or at the mere presence of an habitual tormentor.

The examinant will by no means find so good an opportunity abroad, when the horse, according to custom, shall have been set upon his mettle, and when his own attention must inevitably be divided. The stall is also a good situation in which to judge of the temper of a horse, his condition, sound or infirm method of standing.

Your intended purchase is now led out, and so much care has been probably used, during the ceremony of bridling and combing, to arouse his natural and supply him with an addition of artificial fire, that 'ware horse' is by no means an unnecessary caution to the by-stander. He is taken to a spot of ground raised for the purpose of shewing his fore-quarters to advantage. Here you have an opportunity of making another general survey, in a good light. It is in this situation you must make a final judgment respecting that most material object, his eyes, taking care to have his head placed favourably for your inspection. The next consideration is, the condition of his legs, that he stand straight, and do not knuckle with his knees, that his joints do not tremble

(the sure indication of weakness), and that his feet are even and a just distance apart. Order him next to be walked forward in hand, placing yourself immediately behind him, that you may see how he divides his legs, whether he be straight in his hams, and go sufficiently wide behind, and close before. Keep your position, and let him trot back (still in hand), and you will perceive whether he bend his knees, and go free from cutting or knocking, whether his feet be sound, and his joints free from stiffness, or injury from hard labour.

After these preliminaries, you may permit the jockey in waiting to mount, who ought to exhibit a fair specimen in every pace, walk, trot, canter, and gallop; you having placed yourself in the interim about mid way of his intended course, forward and back again; in which advantageous situation, you may command a view of the horse, his figure and action, in all directions. In this part of the shew, the particulars to be noted chiefly, are, how the horse carries his head, the degree of freedom he possesses in his shoulders, whether he goes well above his ground, and safe; whether his haunches follow well, and without over-reaching, and whether he submits to the touch of the spur without sucking in his wind, and swelling, which is a sure indication of a rebellious disposition, and that he obeys with reluctance. At the concluding scene, the nag is brought back to that elevated spot just mentioned, when you take another cursory view of him, and he returns to his stable.

But I would advise no person, however accustomed to horses, to purchase one for his own use, without previously riding him a *trial* himself; a privilege which no dealer of credit refuses, to the extent of two or three miles upon the road, in company with himself or servant. It is undoubtedly the way to know all that can be well known of an animal, in so short an acquaintance, first to see him ridden, and then to ride him yourself. You will be enabled to determine, how far his merit is to be attributed to the skill or spurs of the jockey, how far his condition and wind are to be depended upon, and whether he has been merely pampered for sale; whether his carriage be adroit, careful, and safe, over rough ways; whether he be naturally shy or skittish, or has taken aversion to particular objects; and whether he trot down hill in a firm and compact way, naturally throwing his weight upon

his haunches, and bearing light on the hand, or whether he lean forward, as desirous of using his nose as a fifth leg. This last is a consideration never to be overlooked. A hack that will not go well down hill, may fairly be pronounced good for nothing, were it only because such good qualification is generally the consequence of being well-shaped, and the backward position of the shoulder, and the inclination forward of the haunches, favouring the attitude most proper for descent. Last of all, there may be something highly disagreeable in the motions or carriage of a horse, which a person can by no other means discover, than by actually riding him; and I have frequently heard men of consummate judgment acknowledge themselves much deceived by trusting entirely to shew.

In the trial of a horse, however, I would much rather ride him a few miles on the road, without the company of either the seller or his servant; and for the following reason:—A restive horse will frequently go quietly enough in company, and proceed without the least hesitation; whereas, if taken along the road alone, and particularly when ridden by a stranger, he will not fail to shew his tricks.—Shy or timid horses pass strange objects much better in company than when ridden alone.

The best mode of forming an opinion of the eye or sight of a horse, is to stop him just as he is coming out of the stable. He should be so placed, that his head appears on the outside the door-place, just sufficient to enable the light to fall softly on the eye, a situation of all others the best calculated to detect any defect or injury of the eyes.

The bargain for a horse is either attended with the WARRANTY of “sound,” free from vice or blemish, “and quiet to ride or draw,” or he is sold without warrant, to be taken with all faults; in which latter case, the buyer can have no right or pretence to return him, except he prove glandered, which exception I suppose arises from the illegality of selling any horse in that state.

SOUNDNESS, not diseased, lame, blind, or broken-winded: nor having, at the time of sale, any impending cause thereof. By custom, three days’ trial are allowed the purchaser, within which period the horse ought to be returned for unsoundness: but if the defect lie hid, and the horse can be proved to have been unsound at the time of sale, a much longer detention

does not bar the return of the horse; on the other hand, if the seller can prove the soundness, it is presumed the horse has been damaged while in the custody of the purchaser, who in such case must sustain the loss. In cases of this nature, as well as all others, justice must depend on the last resort, upon the judgment and integrity of the evidence.

The impending causes of unsoundness are various; such as rottenness, defects in the eyes and wind; splents, and spavins. The trial of a horse's soundness ought to be committed to a person accustomed to horses. Our judgment, as to the goodness of the wind, is now universally guided by the soundness of the cough; but, independent of that criterion, the preternatural heaving of the flanks in a broken-winded horse, will always be sufficiently apparent, if he be put upon a swift pace. It is necessary to try the new purchase in all paces, and even to ride him fairly a considerable number of miles, in order to discover any latent defect, or lameness of the sinews, which may have been patched up with bandage and astringents, for the express purpose of sale.

**BUZZARD.** This large and well-known bird is of a sedentary and indolent disposition: it will continue for hours upon a tree or eminence, whence it darts upon such prey as comes within its reach. It feeds on birds, small quadrupeds, reptiles, and insects. It is extremely injurious to young game, and therefore keepers should be careful to destroy the insidious thief. It is not easy to be approached within gun-shot, but may be easily caught in almost any trap, baited with almost any kind of flesh or a small bird. They are easily caught with a young rabbit for a bait, if the place where he perches be found, for he keeps his haunt regularly.—A roach is also a good bait for the buzzard. Another way to take him is with a middle-sized square steel trap, baited with fresh bullock's lights; the jaws of the trap must be lightly covered with moss, and wild or tame pigeon's feathers scattered round; the trap must be pegged down. They deposit their eggs frequently in the old nest of a crow, and are easily destroyed during the breeding season.

**BUZZARD**, ch. bred by Mr. Bullock, in 1787, by Woodpecker, out of Miss-fortune. In 1789, at Newmarket, Oct. 31, 2 years old, Buzzard beat Mr. Fox's

Hope, 8 years, by Florizel, T. Y. C. 50gs. Nov. 2nd, he beat Mr. Dawson's Sulky, 3 years, by Garrick, out of Sportsmistress, T. Y. C. 50gs. At the Craven Meeting, 1790, he beat Mr. Vernon's Trial, T. Y. C. 100gs.: May 10, received 50gs. from Mr. Windham's Gallipot; Nov. 13th, beat Mr. Panton's Ostrich, 8st. 10lb. each M. M. 200gs.; same day, Mr. Vernon's Crazy, A. F. 200 guineas. In 1791, at the Craven Meeting, Mr. Panton's Ostrich, 8st. 2lb. each, A. F. 250gs. At the first spring meeting, the Duke of York's Glaucus, R. M. 200gs.; at the second spring meeting, received 120gs. from Lord Derby's Prince Le Boo, A. F.; at the July meeting, Mr. Panton's Griffin, 8st. each, R. M. 300gs.; and, in August, two £50 at Chesterfield. In 1792, 5 years old, 200, 100, 100gs., £50, 100, 200, 37 and a half, 200, 100, 50gs. at Newmarket. In 1793, the Craven stakes, 200, 200, 80, 100, and 60gs. at Newmarket. In 1794, the Craven stakes, 50gs., the Jockey Club plate, 200gs. £50, and 100gs. at Newmarket. He afterwards covered at 10gs. and 10s. 6d. the groom, at Newmarket, and two seasons in Yorkshire, on the same terms. Buzzard was sire of Quiz, (out of Miss West) winner of the St. Leger in 1801, and of Bronze, (out of an Alexander mare) of the Oaks in 1806; also, of Brainworm, Bustard, Castrel, Deceiver, Piccadilly, Rubens, Selim, Augusta, Blowing, December, Eryx's dam, Fanny, Hornby Lass, Little Peggy, Merry Maid, Pantina, Ralphina, Ringtail, Rosamond, Sophia, Tooe, Vanity, &c. &c. This capital racer and stallion left England late in 1804, and died in Kentucky, 1811, aged 24.

**BYERLY TURK**, THE, was Captain Byerly's charger in Ireland, in 1689.—He was sire of the Duke of Kingston's Sprite; the Duke of Rutland's Black Hearty, and Archer; the Duke of Devonshire's Basto; Lord Bristol's Grasshopper; Halloway's Jig; and Knightley's mare.

**BYWELL TOM**, ch. (afterwards called **LIGHTNING**,) the property of Mr. Fenwick, foaled in 1747, was got by Cade, dam by Partner, grandam by Woodcock; great grandam by Croft's Bay Barb—Makeless—Brimmer—Dicky Peirson—Burton Barb mare. Bywell Tom won £1000 in £50 plates: he served mares in Shropshire and Staffordshire at 2gs.

# C

**CADE**, a bay horse, foaled in 1734. Bred by, and the property of, the Earl of Godolphin. Cade was got by his lordship's Arabian, out of Roxana, the dam by Roundhead and Lath. At Newmarket, in October, 1740, Cade won the King's plate, beating, at two heats, Mr. Martindale's Sedbury, Sir Michael Newton's Elephant, and the Duke of Devonshire's Blacksilver. Cade started at Newmarket in April, 1741, when he was beat by Sedbury. He only ran three or four times, and proved unsuccessful. Cade was sold to Mr. Thomas Meredith of Eastby, Yorkshire, where he became a favourite stallion, and was sire of Match'em, Changeling, Young Cade, and a great number of celebrated racers, stallions, and brood-mares, as will be found in the various pedigrees. Cade died at Eastby, in September, 1756, aged 22. He covered in the spring of that year at 10gs.

**CADENCE**, is an equal measure or proportion, observed by a horse in all his motions, when he is thoroughly maneged, and works justly at gallop, *terra a terra*, and the airs : so that his times or motions have an equal regard to one another : that one does not embrace or take in more ground than another, and that the horse observes the ground regularly,

Horsemen say, "This horse works always upon the same cadence ; he follows the cadence ; he does not change his cadence ; he remains equally between the two heels.—He is gentle in all his aids ; and when put to the manege, he never interrupts his cadence.—This horse has so fine a mouth, and works with so much liberty in his shoulders and haunches, that he keeps his cadence with great facility : nay, he takes a very good cadence upon his airs, without stepping false, without jumbling, and works equally in both hands."

**CÆCUM**, the **BLIND GUT** ; so called from its being open at one end only ; called also *monomachon*, and *monocolon*. This intestine, which is about three fingers breadth long, is hid by the last convolution of the ilium. It hath the same bands as the colon, which bands take their origin from the *appendicula vermiformis*. Its diameter is more than double that of the small intestines.

**CALCULUS** ; the disease called the **STONE**. By the *stone*, is understood a calculous concretion of the kidneys, or in

the urinary bladder, which is too large to pass.

Dr. WITHERS, of Newbury, communicated to the Medical Society of London, the following curious facts respecting intestinal concretions in horses.

"Many years ago," says he, "I gave the late Dr. W. Hunter a large intestinal stone of a horse which proved fatal to the animal ; and some years afterwards, I saw an engraving of a section thereof in the doctor's possession. Subsequent to this period a like instance happened in this neighbourhood ; and what then seemed to me singular was, that the horses belonged to *millers*. This circumstance excited my attention, and from enquiry I found that their horses were more liable to this disease ; which observation I have long noticed to my medical friends. Their food, I am informed, is chiefly composed of bran and split beans, the mucilaginous part whereof is a favourable medium for associating the strong particles abraded in trituration. Another circumstance may also contribute towards the generating these concretions ; their horses are generally watered at a river, and for the most part below the mill. This water being in constant agitation by the rapidity of the stream necessary for turning the wheel, must necessarily raise and keep afloat small sabulous particles, many of which must be taken into the stomach. I am the more confirmed in this opinion by conversation I have had with a friend of mine, who constantly keeps upwards of a hundred draught horses, none of which he has ever lost from this disease. His manner of feeding is to give them bran, oats, and beans, either *whole*, or split by means of a *steel-mill*. Some years since, when attending the late Mr. Andrews, miller, of Shaw, near this place, he informed me of his having a very valuable horse ill with the colic, and which he supposed would die ; I told him, that if he would have the intestines examined, he would find a large stone in them, which was the cause of the horse's illness ; he laughed at the prediction, and consequently neglected the enquiry. On visiting a few days afterwards, he produced a large round stone, broken, and informed me the dogs in eating the intestines had made the discovery. Since the death of Mr. Andrews, his son has lost a valuable horse from the same cause. He tells me that

his father had reason to believe, that in his time, he lost two more valuable horses from the same disorder. To these instances of the loss of millers' horses I could add many others proceeding from the same cause. Mr. Andrews has, by my advice, for these several years past, changed the diet of his horses. He gives them bran, and beans not *split*, with a certain proportion of chaff; he supposes the beans to contain the greatest proportion of stony particles, as they are ground by stones softer than those which are used for grinding wheat. Since this time he has had no reason to think that any of his horses have stony concretions formed in their bowels; nor such appearances in their *fæces*, as he recollects formerly to have observed."

Dr. Withers also observes, that masses, or accumulations of a less dense texture, are sometimes found in the intestines of horses. He says: "My friend above alluded to, has informed me, that in the course of the last 30 or 40 years he and his father have lost three or four horses in consequence of obstruction in the bowels, arising from large lumps of spongy substance, which had rather the appearance of *indurated fæces* than of *stone*, and which, on being exposed for some time to the air, mouldered away. Some of the stones, however, alluded to in the foregoing account, were of so hard a nature as to be capable of receiving a very fine polish."

CALOMEL, is a medical article, well known by this name as the mildest preparation of mercury: it is in general use in private practice, and a certain specific for the obliteration of worms in horses, when added in proper proportions to the ingredients for purging-balls.

CANKER is a diseased, debilitated, and vitiated action of the vessels that, in a state of health, are meant for the secretion of the sensible sole of the foot. It is generally to be found among the large, heavy class of horses, and particularly in the posterior extremities, from their being in the stable constantly exposed to the unhealthy qualities of the dung and urine. It consists of a formation of a fungous nature, frequently with appearances of the fibres of roots. This diseased production will sometimes obstinately resist the effects of the most active astringents, and the discharge from the contaminating vessels is so powerful, as to corrode and assimilate almost every part with which it may hap-

pen to come in contact. The disease termed *FRUSH*, or *THRUSH*, when neglected, will become canker.

When canker is only in its infancy, every diseased portion of the foot should be removed by means of the *drawing knife*, or other instrument. The surface of the insensible sole and frog must then be accurately examined, and every part of the fungous production removed. When a corrosion of the coffin bone, or of the cartilages has taken place, exfoliation is requisite, and may be procured by the application of the actual cautery to the affected spot. The wounds may then be dressed with dossils of tow moistened in spirits of turpentine, tincture of myrrh, or compound tincture of Benzoe. A bar-shoe will be preferable; and the cavity between the foot and the shoe should be so completely filled with tow, or other soft substance, as to produce a firm degree of pressure on the diseased parts. By the assistance of narrow plates of thin iron, applied across each other, having their ends within the shoe, this dressing will be properly retained: where the case will not admit of a shoe, the operator will find no difficulty in substituting some other method.—In about four days, the dressing may be removed, and another applied, composed of honey and burnt alum, which may be repeated every two days. Attention should be paid that the animal is so situated as to prevent, as much as possible, the admission of external moisture, and should the formation of the new substance prove of a fungous, pulpy disposition, a little powder of vitriolated copper or verdigris, may be sprinkled on its surface.

CANKER IN DOGS—See DISEASES OF DOGS.

CANTHARIDES. Spanish flies, the principal ingredient in every composition prepared for the purpose of blistering;—some of which are in the form of ointments; others, less powerful, are applied as liquids, and called liquid blisters.

CAPARISON, is mostly used as a military term, appertaining to cavalry regiments, and applicable to the apparatus of every individual; the saddle, bridle, housings, holsters, and trappings of every description.

CAPULET, OR CAPPED HOCK.—A swelling that takes place on the posterior parts of the hocks, and sometimes on the point of the elbows of the fore legs, arising in consequence of some blows on those parts. At other times this kind of

enlargement is formed by an accumulation of water in the aponeurotic expansion of the muscles connected with the joint.

When those enlargements on the point of the hocks or elbows are very large, and taken in their recent state, they generally give way to the frequent application of strong blisters, which must be continued so as to keep up a constant discharge.— But if blisters seem to fail, after a proper and judicious management of them, then you will find that the actual cautery will reduce those swellings, almost effectually, in the course of four or five months, if the operation of firing has been performed with dexterity and judgment.

**CARIES, or ULCERATED BONE,** is a disorder of the bones exactly of the same nature with a sphacelus, or gangrene of the fleshy parts. It is therefore necessary to examine strictly all circumstances, in order to discover if possible what has been the causes that have destroyed the circulation, in the whole or part of the bone: to be able to succeed, we must endeavour to find out whether it proceed from the acrid matter of an ulcer penetrating and destroying the periosteum and the bone; or a violent blow on the bone itself; it is also of great importance to discover whether the cause be general or topical, as in the case of canker in the foot, which often takes place without a manifest cause: except, however, in case of bad greasy heels, and running thrushes, in which cases, horses of this kind often shew a natural propensity for the disorders to run into the foot, and to destroy the bones confined within the hoof.

When a carious bone is deeply situated under the flesh: this part is soft, flaccid, fungous, inflated and tumid; the lips of the ulcer inverted, the sanies clear, subtle, fæted, and black; nor can the ulcer be cured, at least only superficially, and it soon breaks out again.

In this case an opening must be made in the skin, and through the muscles, sufficiently large to reach the diseased bone: if the opening has been made too small, the matter will be detained, and will form sinuous ulcers, or it will be absorbed into the circulation; in either case we must have recourse to the knife again; and taking care this time to make a sufficient opening to allow all the pieces of bones to come out, without which no cure can ever be expected.

But in order to obtain a quick exfoliation of all the rotten pieces of bone, the application of the actual cautery to the

diseased bones will be necessary: and to assist the discharge of matter and rotten bone, let the whole of the carious parts be washed with spirits of turpentine, or oil of cloves, or spirits of wine, or brandy and vinegar; and at night a tent of tow dipped in any of the spirits mentioned, and powder of euphorbium. The actual cautery may be renewed as often as necessity requires, without the least fear of doing any injury; which, on the contrary, is the only remedy to be applied; it will remove safely and speedily all the dead or decayed parts of the bone.

**CARMINATIVES,** are all such warm aromatic seeds or medicines as expel wind, amongst which may be justly ranked most of the spices; likewise aniseed, caraways, cardamoms, ginger, grains of paradise, &c. They are excellent aids in the flatulent disorders of horses; but should not, if possible, have been too long in the shop, as some of them lose their property by long keeping.

**CARP** are esteemed one of the richest fresh water fish we have in the kingdom: they are the principal stock of park canals and manor ponds, to the owners of which they afford considerable profit; particularly near populous cities, where they can be disposed of to advantage at the season when such ponds are drawn, and new stocked with stores. Much success depends upon the nature of the soil where the pond is situate: if in a soft marley kind of earth, or warm clay, impregnated with hazel earth, and a muddy bottom, they thrive beyond expectation; but, upon a dead, black, moory gravel, or a flinty, chalky bottom, they are sterile beyond description, in both growth and propagation. They are a fish so exceedingly shy, (or so exceedingly cunning,) that they afford very little success to the angler, who ought to be one of the most patient adventurers that ever embarked in sporting speculation. They are but little found in running streams or rivers, notwithstanding very large quantities of small store are constantly thrown in from the reservoirs and breeding ponds of gentlemen living in the vicinity of such rivers, not more to get rid of their own superflux, than to promote a friendly supply for the accommodation of their neighbours. In large ponds, well stocked, the poachers are never deficient in means of procuring themselves a share; this they effect by forming a paste of crumbled bread, flour, and treacle, to which they add some of the *coccus indicus* (an Indian berry) in

powder: this being well incorporated, and thrown into the pond in various parts, about the size of common baits, in the latter part of the evening, the fish will be found at daylight in the morning floating upon the surface in a state of stupefaction, when they are taken out close to the bank without the least difficulty.

**CASTING.** A term used for the throwing down and overpowering a horse, so as conveniently and safely to perform any painful operation upon him. The way to do this is to bring him upon some even ground that is smooth and soft, or into a barn, upon soft straw; then take a long rope, double it, and cast a knot a yard from the bow; put the bow about his neck, and the double rope betwixt his fore-legs, about his hinder pasterns, and under his fetlocks; when you have done this, slip the ends of the rope underneath the bow of his neck, and draw them quick, and they will overthrow him; then make the ends fast, and hold down his head, under which you must always be sure to have plenty of straw, to prevent his beating it against the ground.

**CASTING NET.** In a half extended form, (when in part suspended from the ground, and resting on the leads fixed to its bottom) it resembles a bell in its shape; but when *cast* in the water, or spread on the ground, it constitutes a complete circle. They are made of different dimensions; and so constructed, as to be completely grasped by the right and left hand, having the centre of the net spread over the left shoulder; when, by a sudden exertion, (in which there must be great expertness) the net is so cast as to fall upon the water in its *utmost circular extent*; where sinking with all possible expedition, by the weight of the lead affixed to its edges, which now reaching the bottom, incloses within it all the fish in the space so covered, and from whence no one can escape. To the centre of the net is fixed a line of twelve feet long, which line, in throwing (or casting) the net, is of course extended, the extremity being previously fastened to the wrist: when the leads have reached the bottom of the water, and rest on the ground, the fish rise into the bell part of the net; then the person having the line in hand begins to draw the net gently to land.

**CASTRATION.** Much difference of opinion exists as to the proper time of castrating colts. In the more common sort of horses, it is probably indifferent at what time the operation is performed, and three months, if the weather be not hot,

is as good as any. But when the breed is prized, and any considerable expectations are formed on the colt, it is prudent to wait till twelve months. At this period he should be accurately examined, and, if his fore parts appear correspondent to his hinder, proceed to castrate; but if he be not sufficiently grown up before, or if his neck appear too long and thin, and his shoulders spare, he will assuredly improve by being allowed to remain entire for six or eight months longer. Young colts require little preparation; but those of more mature growth should be bled and lowered in their system.

**METHOD OF CASTRATING.** Having cast the horse on his left side, secure the off or upper hind leg with the flat web part of a halter. This must completely secure the leg before the hobble is removed from it; after which the leg is to be drawn forward, by means of a web collar around the neck, in the manner of the sideline, and then carefully fastened. Having every thing in readiness, grasp the scrotum firmly with the left hand, and with the right make a section towards the pending part of the bag by a neat flexion of the scalpel, through the integuments, and of sufficient length for the testicle to protrude itself through. Grasping the testicle with one hand, with the other push the scrotum back, so as to expose the spermatic cord, on which fasten the clams sufficiently tight to prevent its slipping, and then dissect or cut away the testicle, leaving a small portion of the cord without the clams for searing. To this end of the cord, while held by the clams, apply the firing iron, sufficiently hot to produce an eschar that will stop the bleeding, but not, as is frequently done, so hot as to burn it to a cinder. Having finished this, proceed to make another section, and to remove the other in the same way. Dress the parts after the operation with mild spirits, or the common tinctures, which may be done or not at pleasure. In colts, no dressing at all is required, nor any kind of bandage; neither is any bandage desirable in more adult horses, as it is apt to get stiff, and become difficult to remove.

In this operation the principal cautions requisite are, first, the necessary force required to hold the clams, without wounding or materially bruising the cord: if it be held very tightly, more inflammation often follows than we could wish; and even the portion of cord held, sometimes sloughs off. If it be not held sufficiently tight, still greater evils may ensue; which

are, the escape of the cord into the cavity of the belly before searing, and an alarming hæmorrhage.

CATARACT, is an opacity of the crystalline lens, or its capsula, occasioning a loss of sight, by the rays of light being prevented from passing to the retina.—Cataract very seldom takes place without a previous inflammation of the transparent cornea and conjunctiva; but this is not the case in the human subject, for they have cataracts formed without any appearance of a previous ophthalmia, and their cornea may inflame without producing cataract. The pupil, at the beginning of this disease, is very much affected, and there is some lymph at the edge of the iris; sometimes the lens escapes from its capsula through the pupil, and comes in contact with the cornea; at other times it rolls about the eye, and produces absorption of the vitreous humour, choroid, iris, and, in short, of all the globe, in consequence of the lens being thickened, and sometimes bony.

In the human subject an operation is performed for extracting the cataract, which is generally successful in giving a little sight to the patient; but in horses it is of no service, because the important functions of the lens must be supplied by two different sorts of glasses; one convex, to see near objects; another concave, to see distant ones. Now the impossibility of employing glasses with advantage to the horse, and without them vision is so confused, for want of the lens, that it is much better to have the animal quite blind; for he would be so continually stumbling and starting at every object, that he would be of very little value to the owner. The only advantage of extracting cataract to a horse, would be when the animal is turned to grass; such as brood mares, for instance. In this case, the operation should always be attempted; I say attempted, because the operation of extracting cataract in horses is extremely difficult to perform, on account of the retractor muscle drawing the eye into the orbit; so much so, that we cannot get at the cornea without a proper instrument: besides, this part is much less convex than the cornea of the human subject; which also adds to our disadvantages.

When the operation is performed, the action of the retracting muscle must be contracted by means of double tenaculum, which is much better than any spiculum we can use. Another difficulty arising after the operation is performed, is, that the retractor muscle still continues to

draw the globe into the orbit, and the aqueous humour is continually escaping, and thereby preventing the union of the divided cornea, which, from the irritation produced, inflames, so does the iris, and all the other parts, and the bulk of the eye is very considerably diminished. I have observed that it sometimes happens that the iris gets between the divided parts of the cornea, and prevents the escape of the aqueous humour; in this case the wound heals, and the operation succeeds. On this advantage, therefore, I recommend the operator to proceed in the following manner, viz. in cutting the cornea, instead of dividing it altogether, we must take the greatest care to leave a slip undivided, by which we are enabled to withdraw our knife with greater safety.

The same method must be attended to when the cataract is depressed, because the only difference in the two operations is, that in the one the lens is completely extracted out of the eye, and by depressing it, is sunk into the bottom of the orbit only.

Either of these operations may be performed when the lens is very white, and of a disagreeable colour and appearance; or, in case of a collection of lymph behind the lens, and the vitreous humour diseased.

CATARRH, OR COLD. This is a disease extremely frequent to horses, and popularly known by the name of cold.—But as we have many examples of catarrh having terminated fatally, from having been neglected at first, or perhaps its symptoms having been mistaken for the strangles, or with some affections which are very different from one another, it will then become necessary to point out the most characteristic signs of a cold.

This disease generally begins with some difficulty of breathing through the nose, and with a sense of some fulness stopping up that passage, attended with the distillation of a thin fluid from the nose, and sometimes from the eyes; and these fluids are often found to be somewhat acrid, both by their taste, and by their fretting the parts over which they pass. Sometimes cold shiverings, and the animal is more sensible than usual to the coldness of the atmosphere; and, with all this, the pulse is more frequent than ordinary.—The difficulty of breathing is evident by a sense of tightness in the flanks, with a cough, which seems to arise from some irritation at the glottis. This cough is generally, at first, dry and painful. With

all these symptoms the appetite is impaired; some thirst arises in consequence of the fever, which is generally more or less high. These symptoms mark the height and violence of the disease; but commonly it does not continue long. By degrees, the cough becomes attended with more copious excretion of mucus, which is at first thin, but gradually becoming thicker, is brought up with less frequent and less laborious coughing; the febrile symptoms abating, the running at the nose becomes again less, till at length they cease altogether.

Such is the general course of this disease, neither tedious nor dangerous; but such a favourable termination is, sometimes, in both respects, otherwise. If the horse has been put to work, or the body exposed to fresh cold, the disease, which seemed to be yielding, is often brought back with three times greater violence than before, and is rendered not only more tedious than otherwise it would be, but also more dangerous, by the supervening of other diseases, which often passes into inflammation of the lungs, a disease in horses attended with the utmost danger.

In horses of a phthisical or broken-winded disposition, a cold may produce tubercles in the lungs, and in horses that have tubercles already formed in the lungs, it may occasion the inflammation of these tubercles, and will, consequently, render the horse completely broken-winded.

**CURE.** In the case of a moderate disease, it is commonly sufficient to avoid cold, and keep the animal at rest for some days, upon warm mashes of scalded oats and bran, with plenty of water-gruel for his drink, made warm; clysters are also very useful. But in some cases, where the fever and cough become very high, the head as well as the body should be well clothed: we must take away more or less blood, according to the violence of the symptoms. If there is a great difficulty of breathing, a blister is to be applied to the throat and windpipe, from the jaw-bone to the insertion of the chest. At the same time we must give the following balls, viz. Take tartarized antimony, nine drachms; calomel, two drs.; sulphur, three ounces; opium, three drs.; treacle, sufficient quantity to form the mass; to be divided into six balls, one of which must be given every morning or evening. A considerable advantage will be derived from the use of these balls, which must be continued as long as they seem to be required.

**CATHARTICS.** Synonymous with Purgatives.

**CAUSTICS**—are medicines which externally constitute a destruction of the texture (or superficies) of the parts to which they are applied. Caustics are of different kinds, and of various powers, according to the reduction, or extirpation, for which they are intended. The actual cautery, or red-hot iron, is used in firing, as well as for the farther prevention of sand-cracks already broke out. The antimonial caustic, or butter of antimony, (in judicious hands), is a complete and perfect cure for *poll evil*, *fistula*, *quittor*, and *canker in the foot*. Lunar caustic is an admirable counteraction of warts, and fast-shooting fungus. Red precipitate is an excellent substitute, when so much strength is not required; few wounds in horses can be brought to a favourable state of cicatrization without it.

**CAVISON.** The use that is now made of it is to securely hold colts, or stiff untractable horses; formerly, they made use of it, to bend and confine the horse's head, in situations very unnatural and painful; but as this old system is laid aside, and a much better one adopted, I need only explain the modern cavison.

It consists of an iron nose-band, having a joint in the centre, and loop, or eye, to buckle the rein to; the edges of the band on each side this centre-joint, which fixes on the nose, is turned in and jagged to operate severely, as the horse makes resistance; two other joints, one on either side, from which joints the iron part is continued smooth and flat, from three to four or five inches, agreeable to the size of the cavison. At the end of which, there are eyes for the fixing a leather strap to the near-side, and a buckle to the off-side, which buckles under the jaw; two other loops, or eyes, are made in the iron strap close to the joint for fixing the head-stall to. The head-stall, fixed as above, is made to take in or let out with a buckle and front, like unto a bridle. The throat-strap must be fixed at that part of the head-stall, on each side, that comes nearest the eye, that when buckled tight under the jaw will prevent the head-stall chafing the eye by the play, which the cavison must unavoidably have. A rein or rope, about fifteen feet long, and sufficiently strong, fastens by a stout buckle and billet to the loop in the nose-band.

**CHACE.** A chace is, in general acceptance, considered a receptacle for game, interspersed with *fern*, *thickets*,

*underwood*, and probably with *small coverts*, for its preservation. It is understood to be superior to a park, but inferior to a forest, having none of those laws for its protection. It is not unfrequently the property of a subject, and is then protected by its own manorial rights and privileges. CHACES there are, also, the property of the CROWN; and those are generally regulated by the FOREST LAWS, as in the case of *Cranbourne Chace*, situate in Windsor Forest.

CHAFING, so called, is a loss of hair, and laceration of the skin, by the pad of the saddle having got too hard in the stuffing from constant use, and for want of timely circumspection. It is also frequently occasioned by the extreme heat and friction, in continuing to travel *very long stages* in the hotter months, without more frequent relief or rest to the horse. This is a very common fault, or act of indiscretion, with the commercial part of the community; who possessing rather too much of the *spirit of trade*, anxiously endeavour (in the extent of their sagacity) to do much more, in less time, than nature ever intended, by *humanely* travelling a horse *two stages* instead of *one*, thereby saving most arithmetically one half the expence, upon the city principle of Old Philpot, that “a penny saved, is a penny got.”

There cannot be a more prudent precaution in either sportsman or traveller, than an occasional inspection of the *stuffing* of the *saddle*, which invariably gets hard with constant use; it should sometimes be beat and softened with a stick, afterwards lightly raised in every part with the point of a packing needle, and made smooth and free from the lumps upon the surface, by which means every chance of injury will be avoided. Nothing can be productive of more anxiety than a sore back of the horse, either to the traveller on his journey, or a sportsman in the field; or any thing more mortifying, than to recollect such injury originated in the *neglect* of the *master*, and not in a fault of the horse. The backs of some well-bred and thin-skinned horses, particularly young ones, are subject to *chafing* and *warbles* upon very slight occasions; to counteract which, nothing can be better, more simple, or more easily obtained, than two or three table-spoonsful of the best white wine vinegar, bathed cold upon the part, and that so soon as the saddle is taken off, and while the pores are open.

CHALLENGE. When a hound gives tongue on being thrown into cover, he is

said to challenge. If the challenge come from an old hound, one to be depended on, the huntsman immediately cheers—“*Hark! to Rattler*,” when the pack make to the challenging hound as fast as possible; and reynard most likely breaks cover in a few seconds or a few minutes. If the challenge be from a young hound or a babbler, the huntsman remains silent.

CHAPELET, in the manege, a couple of stirrup-leathers, mounted each of them with a stirrup, and joining at the top in a sort of leather buckle called the head of the chapelet, by which they are made fast to the pommel of the saddle, after being adjusted to the rider's length and bore. They are used both to avoid the trouble of taking up or letting down the stirrup every time that a gentleman mounts on a different horse and saddle, and to supply what is wanting in the academy saddles, which have no stirrups to them.

CHAPERON of a BIT-MOUTH, a term used only for snatch-mouths, and all others that are not cannon-mouths, signifying the end of the bit that joins to the branch just by the banquet. In snatch-mouths the chaperon is round, but in others it is oval; and the same part that in snatch and other mouths is called chaperon is in cannon-mouths called froncean.

CHARBON, in the manege, that little black spot or mark that remains after a large spot in the cavity of the corner tooth of a horse. About the seventh or eighth year, when the tooth becomes smooth and equal, it disappears.

CHARGE, in the old practice of farriery, a preparation of a middle nature between an ointment and a plaster, or between a plaster and a cataplasm; or participating of all three, viz. being partly made up of oils, meals, pulps; and partly of gums and resinous things, that give a stiffness and body to plasters. And therefore, as all charges are only a kind of soft or liquid plasters, the ancients, who first contrived them, made greater use of them than any other topic whatever in all outward diseases, as being the best adapted to creatures that are covered with hair.

Charges are of different intentions, as are all other forms of outward application; some being chiefly emollient, others discutient, and some repellent, of which kind are most of those called *cold* charges; some of which are also styled defensive or strengthening. Their principal use is to restore parts that are weakened by falls, bruises, or any other kind of accident.

The following is a specimen of this kind of composition:

Take of Mastic,  
 Dragon's blood,  
 Myrrh,  
 Gum tragacanth, of each one  
 ounce;  
 Common pitch, six ounces;  
 Bole,  
 Litharge in fine powder, of  
 each two ounces.

Boil all these in a sufficient quantity of vinegar over a slow fire, until they grow ropy; then take them off, and add bole ammoniac in fine powder sufficient to make a char ge.

This is described to be of great service in strains, and to abate the heat and inflammation that attend large wounds, being applied over the dressings. It is likewise used in inflammation of the eyes, being laid all over the head and temples.

A variety of other charges may be met with, under their several names, in the course of this work; but the curious reader will be gratified by consulting Gibson's Farrier's Dispensatory upon this subject.

CHASE, THE. This article is here introduced in a general sense; and we may therefore observe, that the chase is the pursuit of animals which, in a state of savage nature, constitute the principal support of human existence, but in Europe is followed as an amusement, as well as to increase the luxuries of the table. Savage man uniformly attempts to supply his wants in that way which most obviously presents itself to his view; and hence the stream or the chase is the first resort to supply the cravings of his appetite. What, therefore, arose from necessity, became at length the diversion of polished society. The snare, the bow, and the spear, were used in the primitive ages for procuring subsistence; however, the science of the chase has undergone various changes or improvements, and has arrived at that pitch of perfection, in this country at least, that very little trouble would be requisite totally to exterminate those creatures legally denominated game.

In the more early ages, hunting was, strictly speaking, the labour of the great, and was practised on a scale of grandeur unknown to modern times. Indeed, in England, those animals have been extinct for ages which afforded a dangerous pastime to princes and their vassals; and in most parts of Europe their numbers have been so thinned, that they are scarcely known, except for their nocturnal ravages on the peaceful flock. Various methods

were employed for the destruction of wild and ferocious beasts; but in the grand hunting parties, nets of immense strength and extent were used, to encircle a spot into which the animals had been previously driven, and a general slaughter ensued. But as man improved in civilization, the cultivation of the soil became an object of his particular attention; dangerous animals felt his power; their numbers decreased very much in consequence, and in some places they are altogether extinct. Eagles were formerly taught to fly at the stag; and hawks were used to pursue smaller animals, such as hares, rabbits, &c. and were ultimately taught to fly at birds. The sagacity of the setting-dog was evidently known before the introduction of the fowling-piece, the latter of which has superseded the hawk. Different kinds of hawks were employed, according to the objects of pursuit; and the late Colonel Thornton distinguished himself as a falconer, as he did, indeed, in every other department of field sports: he revived, in some degree, the almost forgotten science and amusement of falconry; and since that period hawks have been kept by several other sportsmen, who still retain them. Though hawks have not been used by the British monarch for many years, the office of Grand Falconer is still held by the Duke of St. Alban's, with a salary of £1372 per annum.

Hunting is, perhaps, one of the most fascinating amusements in the catalogue of human recreations, and, though attended with danger, even from the pursuit of the tiger down to the timid hare, is, nevertheless, calculated to inspire courage in a greater degree than any other known stimulus. Such only will perfectly understand my meaning as have experienced those feelings which responsively arise from the music of the pack.

The mode of hunting varies according to the country, or rather according to the object of pursuit. Strange accounts may be found in various historians of the manner in which savages attacked the lion and the tiger with spears, &c. which come in so questionable a shape, that they are unworthy of notice. It is very certain, that where the gun is known, it is uniformly used against the larger and more ferocious animals. Accounts are also given of hunting lions with dogs, which appear as little entitled to credit. In the East Indies, where there are some lions, and where tigers are very common, hunting parties are formed for their destruction

whenever they leave their fastnesses for the purpose of ravaging the more cultivated parts of the country; and it would appear, that on these occasions the hunters are numerous, and armed with muskets or fowling-pieces: they thus seek their object in his retreat: the chase becomes a furious encounter, the most surprising part of which is, the number of bullets the animal generally receives before it is disabled. Indeed, instances have occurred in the pursuit of the wild elephant, where, after firing a great number of musket-balls into it, recourse has been had to small swivel cannon to complete its destruction. In the common mode of taking wild elephants, decoys are used; and they become the objects of destruction only when any one of them happens to be seized with a sort of phrensy or madness (which is sometimes the case), and, leaving the herd, runs wildly into the adjacent villages, tearing up the huts of the natives, and overthrowing every thing which presents itself as an obstacle. But, independently of this sort of casual chase, the great men of the country, at certain seasons, form hunting parties on an extensive scale, in which they are completely armed, riding on trained elephants, and attended on foot by their vassals. It does not appear that horses are much (if at all) used on these occasions; the terror which generally seizes a horse, not only at the sight, but even at the smell, of a lion, tiger, &c. renders him unmanageable; and most persons in this country are already aware of the alarm which a horse manifests on passing a bear. The elephant will occasionally testify great symptoms of fear on smelling a tiger track; but he will, nevertheless, encounter the fierce animal, and often lay him prostrate with a blow of his trunk. It is true, we read of the horse being brought to combat the lion in the amphitheatre of ancient Rome, and of the former having killed the latter by a lucky stroke of his hind legs, as well as of wild horses uniting for their mutual defence; yet the fact is incontestible, that the horse, on the sight of any of the large feline animals, evinces more confidence in his speed than either in his strength or courage, and never fails, unless prevented, galloping away. If dogs are at all used in the eastern hunting parties, it is merely to kill small game, and perhaps to rouse the larger beasts. The musket and spear are opposed to the teeth and the claws of the tiger; and it frequently happens that the latter does not resign the un-

equal contest till some of his pursuers have felt the dreadful effects of his resistance.

The following will enable the reader to form a tolerable opinion of the mode of hunting in the East Indies:—

Hunting, we are told, was a favourite diversion of the celebrated conqueror, Jenghiz Khan; and the East Indian princes still manifest the same disposition for the chase as was displayed by their ancestors; and M. Blanc, who attended the hunting excursions of Asoph Ul Dowlah, vizier of the Mogul empire, and nabob of Oude, in 1785 and 1786, gives us the following account:—

The commencement of the hunting season for the party is about the beginning of December; and the diversion is enjoyed till the excessive heats in the first weeks of March occasion its termination. During this time, a circuit of between 400 and 600 miles is generally made, the hunters bending their course towards the skirts of the northern mountains, where the country is wild and uncultivated. The vizier takes along with him not only his court and seraglio, but a great part of the inhabitants of his capital also. His immediate attendants amount to about 2000; but, besides these, he is followed by 500 or 600 horse, and several battalions of regular sepoy, with their field pieces. Four or five hundred elephants are likewise included in his retinue, some of which are used for riding, others for fighting, and some for clearing the jungles and forests of the game. About as many sumpter horses, of the beautiful Arabian and Persian breeds, are taken also. A great many wheel carriages, drawn by bullocks, likewise attend, which are chiefly used for the convenience of the women; sometimes, also, he has an English chaise or two, with the addition of a chariot; but all these, as well as the horses, are merely for show, the vizier himself never using any other conveyance than an elephant, or occasionally, when fatigued or indisposed, a palanquin. The animals used in the sport are principally greyhounds, of which there may be about three hundred: he has also about two hundred hawks, and a few trained leopards, for catching deer; with many fowlers, who provide game, as none of the natives understand shooting it with small shot, or hunting with slow hounds. A vast number of matchlocks are carried along with the company, with many English pieces of various kinds; forty or fifty pair of pistols, bows and arrows, besides

swords, daggers, and sabres without number.

There are also nets of various kinds, some for quail, and others very large for fishing, which are carried upon elephants attended by fishermen, so as to be always ready for throwing into any river or lake the cavalcade may happen to approach. Every article that can at all contribute to luxury or pleasure is likewise taken under protection of the army. A great many carts are laden with water of the River Ganges, and even ice is transported for cooling the drink. The fruits of the season and fresh vegetables are daily sent to him from his gardens by bearers stationed at the distance of every ten miles; by which means each article is conveyed day or night at the rate of four miles an hour. Besides the animals already mentioned, there are fighting antelopes, buffalos, and rams in great numbers, fighting cocks, &c. To complete the magnificence or extravagance of this expedition, there is always a large bazaar or moving town which attends the camp, consisting of artificers, shop-keepers of all kinds, and dancing women; so that, upon a moderate calculation, the whole number of people in and dependant upon his camp cannot be computed at less than 20,000. The nabob, with the attending gentlemen, proceed in a regular moving court or durbar, and thus they keep conversing together, and looking for game. A great many hares, foxes, jackals, and sometimes deer, are picked up by the dogs as they pass along; the hawks are carried just before the elephants, and let fly at whatever game is sprung for them, which are generally partridges, bustards, quails, and different kinds of herons—these last affording excellent sport with the falcons or sharp-winged hawks. Wild boars are sometimes started, and either shot, or run down by the dogs and horsemen. Hunting the tiger, however, is looked upon as the principal diversion; and the discovery of one of these animals is accounted a matter of great exultation. The covert in which the tiger is found, is commonly long grass or reeds, of such a height as frequently to reach above the elephants, and it is difficult to find him in such a place, as he steals off, if possible, or lies so close, that he cannot be roused till the elephants are upon him. He then roars, and skulks away, but is shot at as soon as he can be seen, it being generally understood, and uniformly contrived, that the nabob shall have the first shot. If the tiger be not disabled, he con-

tinues to skulk along, followed by the line of elephants, the nabob and others shooting at him as often as he can be seen, till he falls. The elephants themselves are very much alarmed at this terrible animal, and discover their apprehensions as soon as they smell him, or hear him growl, generally attempting to turn away from the place where he is. When the tiger can be traced to any particular spot, the elephants are disposed of in a circle round him; in which case he will at last make a desperate attack, springing upon the elephant that is nearest, and attempting to tear him with his teeth and claws. Some, but very few of the elephants, can be brought to attack the tiger; and this they do by curling up their trunks under their mouths, and then attempting to toss, or otherwise destroy him with their tusks, or to crush him with their feet or knees. It is considered fair and good sport to kill one tiger in a day; but it sometimes so happens that a female is found with her young, in which case two or three share the same fate.

The other objects of pursuit in these excursions are wild elephants, buffalos, and rhinoceroses. Our author was present at the hunting of a wild elephant of vast size and strength. An attempt was first made to take him alive, by surrounding him with tame elephants, while he was kept at bay by crackers and other fire-works; but he most sagaciously and courageously avoided every stratagem of this kind. Sometimes the drivers of the tame elephants got so near him, that they threw strong ropes over his head, and endeavoured to detain him by fastening them round trees; but he constantly snapped the ropes like packthreads, and made his way for the forest. Some of the strongest and most furious of the fighting elephants were then brought up to engage him; but he attacked them with such fury that they were all obliged to desist. In his struggle with one of them, he broke one of his tusks; and the broken piece, which was upwards of two inches diameter of solid ivory, flew up into the air several yards above their heads. Orders were now given to kill him, as it seemed impossible to take him alive; but even this was not accomplished without the greatest difficulty. He twice turned, and attacked the party that pursued him, and in one of these attacks struck the elephant obliquely upon which the prince rode, threw him upon his side, but then passed on without offering any farther injury. At last he fell

dead, after having received, as was supposed, little less than a thousand balls within his body.

The nature of a jungle is thus described by Colonel Forrest:—"The height of the grass (says he) struck me as particularly wonderful: I was mounted on a very fine elephant, not less than eleven feet high; the howdah or seat fastened on the animal's back must have been full two feet high, it being strapped on a very thick pad: this would give thirteen feet. Now, when standing upright, the attitude usually adopted by sportsmen when beating a jungle, in order to see better around them, my head must have been near nineteen feet above the ground; but the grass was generally three, and in some places six feet higher than my head. The stalks were full an inch and a half in diameter, and it would be almost impossible, certainly very fatiguing, to attempt to force a passage on foot through such a thicket, independent of the chance of meeting with a tiger on a sudden."

Attempts have been made by British residents in India, to introduce into that country, something like the field sports of these islands; with this view, fox hounds have been repeatedly sent over, as well as pointers and other dogs. There is plenty of winged game in India, which would afford employment for the fowling-piece; and that beautiful bird, the peacock, is found in immense numbers, in a state of nature; but shooting is a dangerous amusement in India, as the game is principally found close to the jungles, where the lurking tiger is concealed, ready to spring upon any victim which happens to come within his reach. Hog hunting is found by the British residents to be the best diversion which India affords, at least for an English appetite. There are plenty of wild hogs in this part of the world, (much smaller than the wild boar of Europe,) which the English residents pursue, not with dogs, but mounted on horseback, with a peculiar dress for the occasion, and each armed with a spear or javelin; they seek the hog in his retreat, and rouse him; he makes off as fast as he can, and is pursued by the horsemen: he who first reaches the hog, attempts to pierce him with his javelin, and passes on; a second reaches him, and does the same; and in this manner the business proceeds till the hog falls. The hog, though he endeavours to get away, is by no means a coward; for when he finds himself unable to avoid his pursuers by

flight, he turns upon them, and sometimes succeeds in desperately wounding some of the horses, though the riders seldom sustain any injury. As to the pursuit of the jackal by hounds, or any thing similar, it has never been attended with satisfaction.

India, in all probability, is the place where field sports were first adopted as an amusement by civilized society; and travelled thence through Persia and Egypt, and thus made their way into Europe, by the same route perhaps as many other arts and sciences.

The greater part of Africa has never yet emerged from its pristine ignorance and barbarism. Those parts of this little-known country, which have, in any age, manifested the intelligence of an enlightened people, are placed, as it were, between Europe and Asia; and here the chase was followed as an amusement, as it is, in fact, in most parts of the world. The princes and great men of these parts, were much attached to the chase; and even Zenobia, the accomplished Queen of Palmyra, was a distinguished huntress: her husband (Odenathus, if our memory be not treacherous,) is said to have put his own son to death for his presumption in being the first to launch his javelin in the chase, that honour being appropriated for the prince.

In Southern Africa, the chase is but little understood by the wretched inhabitants, who are with difficulty able to shelter themselves from the attacks of wild and furious animals. Vaillant, however, gives us a description of a lion hunt.

This interesting traveller met with a kraal (a sort of Hottentot village,) who were labouring under great alarm:—"A lion and lioness (says Vaillant,) had for some time taken up their abode near the horde in an impenetrable thicket. The horde had endeavoured to dislodge them, but in vain, and they still retained possession of their fortress. Every night they issued forth to attack the herd, and even the men; and, the very night before my arrival, they had carried off an ox. Full of hope and confidence in my fire arms, the chief (of the Hottentot horde) congratulated himself on my coming, and requested me to employ my weapons to deliver them from such a scourge, not doubting but I should succeed if I would make the attempt.

The lions obstinately continuing to remain in the thicket, notwithstanding all that had been done to drive them out,

gave me reason to suspect that they had young ones; and this circumstance rendered the attack a business of no usual danger.

These animals, at all times formidable, have, at such periods, a fierceness that nothing can resist. Animated by the necessity of defending and procuring food for their young, they dread no danger, and would face a whole army. It is not courage they then possess—it is raging madness.

Nevertheless, I promised to attack them the next day, and engaged, at least, to drive them away, if I could not destroy them. Considering, however, the closeness of the thicket, and the difficulty of the attack, I required, exclusively of my own people, that those of the horde should also join me. During the night we surrounded ourselves with very large fires, and discharged, from time to time, our muskets. But these precautions were unnecessary; for, the lions, having the remains of their ox to devour, did not appear, though we heard them during a great part of the night.

At break of day, the men of the horde were ready, armed with arrows and assagays, and waited nothing but my orders to proceed to the attack. Even the women and children would be of the party; less indeed to fight than to satisfy their curiosity and enjoy our victory. I heard the lions still growling in their strong hold; but the increasing light soon silenced them. The sun appeared; and the profound silence that then prevailed, was the signal for our departure.

The thicket was about two hundred paces long and sixty wide. It occupied a spot sunk lower than the adjacent ground, so that it was to be entered on a descent. The whole consisted of bushes and briars, except some mimosas which rose in the centre. These trees, could I have reached them, would have afforded me an advantageous position for the attack. On their summits, I should have been secure, and might have shot the animals at my ease; but, not knowing exactly the situation of the lair, it would have been highly imprudent in me to traverse the thicket in order to reach these trees, since I should thereby have exposed myself to the danger of being seized by the way.

Unable to attack these formidable beasts in their entrenchments, all that remained was to tempt them out of their fort; for, it was difficult, not to say im-

possible, to come 'at them through the briars and bushes that covered them, and my marksmen would vainly have attempted to manage, or present with any aim, when thus entangled, their long fusees. I, therefore, determined to place them and the other savages at certain distances from each other upon the eminences all round the wood, so that the lions should be unable to reach the plain, without being perceived; persuaded that in the open country, we should be the stronger party, and finally triumphant.

None of the savages daring to enter the wood, we resolved to force all the oxen of the horde into it. Accordingly, when we were at our posts, with our guns ready to fire, we drove the oxen before us, compelling them by our voices and blows to enter the thicket. At the same time, my dogs opened, and I fired off several pistols to frighten the lions and make them come out.

The oxen, scenting their enemies, soon rushed back with affright, and returned towards us; but our cries, the barking of the dogs, and the report of our arms, compelled them to re-enter the thicket, which they did in a sort of fury, jostling one another and bellowing in a fearful manner.

The lions, on their side, were roused at the sight of danger, and their rage vented itself in dreadful roars. We heard them in every part of the thicket, without their daring to shew themselves any where or advance upon us. The conflict of two armies could not be more loud than their threatening voices, confounded with the cries of men and dogs, and the furious lowing of the oxen. This hideous concert continued great part of the morning, and we began to despair of the success of our enterprise, when I suddenly heard, on the side opposite to me, piercing cries, instantly followed by the report of a gun, which made me tremble. But shouts of joy immediately succeeded; and, passing from one to another along the circle till they came to me, announced a victory.—I ran to the place, and found the lioness expiring. Klaas, who was stationed at that post, had fired and shot her through the body. Her dugs, though without milk, were swelled and pendent, which indicated that she had young ones, and proved that I had not been mistaken in my conjecture.

It came into my head to employ her carcase to entice them out of the thicket. With this view, I ordered it to be drawn

to a certain distance, not doubting but the young ones would come in quest of their dam, and that the male would probably follow, either to avenge or defend them.

I collected at my new post, some of my hunters from right and left, and we retired to the distance of thirty paces from the carcase, ready to fire if the animals advanced. But my stratagem was unsuccessful, and we spent several hours watching for them in vain.

The whelps, indeed, uneasy at not seeing their mother, ran about the thicket, growling on all sides. The male too, on being separated from her, redoubled his roarings and his rage. We saw him for a moment appear at the edge of the thicket, his eyes sparkling, his mane erect, and lashing his sides with his tail. But, unfortunately, he was out of shot of my carbine; and, one of my marksmen, who was posted nearer, fired and missed him. At this he retired; and whether he feared to attack so numerous a body of men, or was unwilling to leave his young, or had received some slight wound, he appeared no more. Though animals of this species, as I have before observed, are more fierce and intrepid when they have young, than at any other period, yet the males are not so much so as the females—a fact well known to the savages.

After waiting for a long time to no purpose, and despairing of the success of my stratagem, I resolved to return to my former plan of attack. In consequence, I sent all the people to their posts, and we again attempted to drive the oxen into the thicket, in order to dislodge the remainder of the family. But they were too much frightened. They all refused to proceed, and I was obliged to give up the design; though my dogs, animated by the blood of the lioness, which they had scented, opened with great ardour, and shewed much eagerness for the sport.

We had spent a considerable part of the day in the chase; the sun was declining, and it would become more dangerous. I deemed it prudent, therefore, to think of retreating, and to defer our final victory till the next day.

The savages conveyed the lioness to the kraal, for the purpose of feasting on her; but, as I was desirous of her skin, I directed this to be first taken off. She was four feet eight inches high to the top of the shoulder; and eleven feet four inches long, from the point of the nose to the extremity of the tail.

When the animal was flayed, Klaas

very naturally threw the skin over his shoulders, to carry it to the kraal, whither he was accompanied by the shouts of all the horde.

The chief requested me to accept four sheep and a couple of oxen in the name of the horde, as a testimony of its gratitude. The sheep I immediately killed, to add to the entertainment which the lioness was to furnish; but the two oxen I gave up to Klaas, who, in fact, had well earned them. At first he refused, and persisted in their being mine. But when I urged to him, that they were presented on account of the death of the lioness, and that this death was his work, he no longer hesitated to accept them.

This feast was the more agreeable, as in part it consisted of the animal which had occasioned so much destruction. I had certainly not the same desire for its flesh as the rest of the guests; yet I was induced to taste it, and found it inferior to that of the tiger.

After the repast came the amusements. The company danced and sung all night, and their revelry did not allow me a moment's repose.

During the night, I heard nothing of either the lion or the whelps; but this I ascribed to the noisy mirth of my savages; and, indeed, had all the lions in the country assembled in the thicket to roar in concert, I know not whether their voices would not have been drowned in the uproar of the feast. There was another reason, however, for this silence. The male, affrighted by the dangers he had run, availed himself of the darkness of the night, to retire with his family; and, in the morning when we returned to the chase, we found the thicket deserted.

From the first movements of my dogs, when they entered the thicket, and their manner of hunting, I perceived that we were too late. To be certain, however, I fired off a pistol a few times, hoping that the animals, if they were still there, would be roused at the report, and soon cause themselves to be heard, either by their growling, or the stir they would make in the bushes.

This preliminary having produced no signs of any thing being present, we cautiously advanced into the thicket, where we found the marks only of the spoil that had been made by this hungry family. On all sides were seen bones scattered about, or lying in heaps; and the sight of this charnel house, reminding the horde of the losses it had experi-

enced, each began to relate and lament his own.

In the mean time I employed myself in tracing the footsteps of the lion and the whelps, to judge of the bulk of the one, and the number and size of the others. Though there are instances of a lioness having three whelps at a litter, this appeared to have had but two; which I had reason to suppose were equal to my great dog Yager, who was as high as my middle, and consequently these were already formidable, and capable of doing considerable mischief.

To judge of the old lion from the print of his foot, which was one third larger than that of the lioness, he must have been of the largest size."

Hence it may easily be perceived that the science of the chase is very little understood in Southern Africa; the wretched inhabitants are, in fact, a very cowardly race; and there is probably no better criterion of the courage of any people than the mode in which they pursue the sports of the field; or rather, perhaps, their courage may be estimated precisely in the same ratio to the ardour which they evince, or the disposition which they manifest, in the chase. The poor, timid, ignorant Hottentot, is incapable of defending himself against the attacks of the formidable animals of the forest; and, though he occasionally appears in the character of a hunter, it is for the purpose of supplying the calls of hunger, rather than from a disposition for the chase; and, even on these occasions, he directs his efforts against the smaller antelopes, and such animals as never offer the least resistance.

The American Indian offers the very reverse of the picture: constitutionally bold, he is not content with merely defending himself against the ravenous wolves and other ferocious animals by which he is surrounded, but pursues them into their very retreats and fastnesses, and seldom fails to effect his purpose.

The Indian, when the American continent was discovered, followed the chase for amusement, as well as to satisfy his wants; and, as at this period, he was unacquainted with the use of fire arms, he accomplished that with the bow, which he has since found so much more easy of attainment with the rifle or the fowling-piece.

When, however, the Europeans came to settle on the American continent (and particularly in North America) there

were not wanting those who were much attached to field sports; and, they endeavoured to find an equivalent, in the varied and desultory chase of that part of the world, for the systematic sporting which they had left behind. The English in particular, who settled in America, pursued the chase with ardour; but, in a manner somewhat different from the system of their own country, owing to the nature of the scene of action, and also from a number of causes, which must always arise from what may be regarded as an infant state of society. The Americans, however, may be said to have gone on improving; and, some idea may be formed of their field sports at present from the following sketch of sporting in South Carolina.

"It may be unnecessary to tell you that the larger portion of our country is one continued forest, interspersed with water, which runs down to our rivers; there are a great number of swamps in the natural vent of our waters to the ocean; their width varies from half a mile to three; they are thick covers, and, therefore, complete shelter for all kinds of game, which are always to be found more or less in them. A day being fixed upon for a general hunt, all the sportsmen meet at a given point with the huntsman and hounds. There are few of us who keep more than ten couple; but, then, every one having some dogs, they make a very large pack when they are all collected: the sportsmen are then equally divided, one half going on one side of the swamp, and the other on the opposite side. They then arrange themselves within gun shot of each other; and, being all armed with double barrellled guns, are ready for the sport, which commences the moment the dogs and huntsman are turned in. The swamps are skirted with fine high pine barrens, which, being open, are famous shooting ground. As soon as the dogs enter, the game runs out, and are fired upon by the first sportsman they come to; they then take back to the cover, and double with the dogs in full cry. It is not unusual, in one of the largest of our swamps, to drive out in one day's hunt, deer, wolves, bears, foxes, wild cats, and a great quantity of wild turkeys, any of which the sportsman shoots as he thinks proper. We never follow *one* deer, after he has made his escape out of the swamp, unless he is wounded, for there is no running down a deer with us: there being so many, that

if the dogs were suffered to pursue far, they would soon be divided into a number of packs: but our wolf we always run down; and, as they are very strong and and large, they will run from three to four and five hours. If they are not shot in the chase, they come to bay in a thick cover, and always turn their backs to a hurricane root (a tree blown up by the wind); where they will defend themselves against the largest pack, their bite being very severe. Our bears, foxes, and wild cats are soon tired, when they always take trees, from which they are shook down to the dogs. The sportsmen particularly admire that part of the diversion, the shooting at wild turkeys which fly out of the swamps while our dogs are in chase; they are very large, fly with great velocity, and are very fine eating. It is remarkable that the English gentlemen, who hunt frequently with us, shoot very badly at our game, and yet will kill the small sorts with great ease. I have known a gentleman shoot on the wing any of our fleet flying birds, without missing a shot, and yet miss five, six, and seven shots at deer and turkies in a day. I attribute this to the agitation occasioned by the velocity with which they pass, and their not being accustomed to them. I have in one day's hunt, seen started forty deer, and ten killed, besides a number of other game. The spoils, after the hunt is over, which is at dark, are equally divided among all the sportsmen, when the huntsmen set off with their respective hounds; and all the sportsmen, with the strangers, are invited to dine at one of the sportsmen's seats, where a general dinner is always provided, and which they all alternately find."

In Europe we find that field sports have always been a ruling passion, from the earliest periods to the present time. It is true, they have varied in their form, either according to the times, or the situation of the country, or both; and are now followed in a very different manner from that which characterized them at very remote periods. Field sports may, in fact, be said to have proceeded hand in hand with the progress of civilization, or rather perhaps of cultivation; and the discovery of gunpowder and the introduction of fire arms, as they completely changed the complexion of, so also they gave to, the chase a very different character from that which had hitherto distinguished it.

The Greeks were fond of field sports, and it is clear from the account of Xenophon

(see the article HARE HUNTING) that the science of the chase was well understood by them. With the Romans the case was very different: these people were the most celebrated warriors the world ever saw; and perhaps from their being almost constantly engaged in scenes of blood, they imbibed that relish for slaughter which formed the leading feature of what might be called their field sports. Most of the nations of antiquity pursued the chase, and feasted on the fruits of it; but the delight of the Romans appears to have been to collect a great number of animals together for the purpose of wholesale or indiscriminate slaughter. Such were the spectacles exhibited in the circus, and victorious Roman generals seemed to vie with each other in the number of victims which they were able to procure for such occasions, in which the people seemed to take great delight; and from which perhaps the bull fights of Spain might be originally derived.

If we descend to more modern times, we shall find the chase in Europe, generally, a very different business from that which it forms at present, owing to causes at which we have already glanced. We will endeavour to exhibit the business in a more conspicuous light by an extract from an ancient author, which, it will be easily perceived, forms a contrast with the practise of modern times. On the subject of hunting the Wild Boar, the author in question observes:—

The boar is ever pigged with as many teeth at first as he shall have ever after, which will only increase in bigness, not in number. Amongst the rest, they have four, which are called tushes or tusks, whereof the two biggest do not hurt when he strikes, but serve only to whet the other two lowest, with which they frequently kill.

They feed upon all kinds of corn and fruit, which they can come at; also roots. In April and May they feed on the buds of palm trees, chesnut trees, and all other sweet buds they can find, especially on the buds of broom and juniper; and are never measled like our tame swine. Being near the sea-coast they will feed on all manner of shell fish.

Their season beginneth in the midst of September, &c. See the article BOAR.

Fire-arms have superseded the use of the spear; and in the modern boar hunts, the animal is fired at as often as opportunity offers. If, however, reliance is to be placed upon the accounts of the chase of

the boar, it is astonishing how long he will stand up before the hounds, as well as the number of balls which he frequently receives before he falls. See BOAR.

The chase of the boar forms a princely amusement in France, as well as in Germany and other parts of the Continent. Bear hunting is followed in the mountains of Spain, as also in other mountainous parts; while the Tyrolese evince much more than common ardour in the pursuit of the Chamois.

The Tyrolese are perhaps the most persevering hunters in the world, and seem to despise all danger in their favourite pursuit. They are such admirable marksmen that their services, as sharp-shooters, in the late war, were rewarded with the temporary liberty of hunting with impunity. The value of this liberty can only be estimated by those who know the passion of the Tyrolese for the chase; a passion more violent than that of the gamester. Neither threats nor punishment can deter them from the pursuit of it. Gain is not the object, as the chamois, flesh and skin, does not sell for above ten or twelve florins; and yet a man who had been many times caught in the fact, declared, that, if he knew the next tree would be his gallows, he would nevertheless hunt. M. de Saussure records an interesting anecdote of a chamois hunter whom he knew; he was a tall well-made man, and had just married a beautiful woman:—"My grandfather (said he) lost his life in the chase and so did my father, and I am so well assured that one day or other, I shall also lose mine, that this bag, which I always carry with me in the hunt, I call my winding sheet, for I shall certainly never have any other; nevertheless, Sir, if you were to offer me a fortune immediately, on condition that I must relinquish the chase, I would not accept it." De Saussure says, that he took several excursions among the Alps with this man; his strength and agility were astonishing, but his courage, or rather his temerity, still greater than either. About two years afterwards his foot slipped on the edge of a precipice, and he met the fate which he had so calmly contemplated.

To come, however, to the field sports or hunting of our own country, we find that a passion for the chase prevailed from the earliest periods. The Saxons were much attached to the chase; but in this they appear to have been far surpassed by their Norman successors.

The Rev. Richard Warren says, that the rural amusements of our ancestors were of a far more noble and manly nature than the puny chases of modern times. The species of hunting in which they delighted was a sport that gave vigour to the frame, strength to the constitution, and nourished that martial ardour and fearless intrepidity, which, when exerted in the field of battle, generally carried off the victory. A great variety of laws were promulgated by the Anglo Saxon monarchs to prevent any of the inferior ranks of people from trespassing on the amusements of the king and nobility, by pursuing or destroying the game. But the inordinate passion which the Anglo Norman kings entertained for this amusement was the source of lamentable ills to their subjects; ills which survived their cause for centuries; and which are scarcely obliterated even at this remote period of time. History may have been guilty of exaggeration; but, setting aside the doubtful account of that devastation which the first Norman William is said to have caused in the southern part of Hampshire, the forest laws are a striking proof of the cruel effects which this blind infatuation produced. Some idea of the Conqueror's high enjoyment of hunting may be formed, not more from the rigorous measures he adopted to secure it from violation, than the princely donations he bestowed on those who assisted in promoting these delights. From Domesday book, we learn that Waleran, the huntsman, possessed no less than fifteen manors in Wiltshire, eight in Dorsetshire, together with several in Hampshire; and his name occurs in the list of tenants in *capite* in other counties. The same venerable remain of antiquity records the extensive possessions of other huntsmen, who bore the names of Croc, Godwin, Willielmus, &c.

But it must be observed, that the Conqueror did not originate the Forest laws in this country, though he very much increased their severity. They were, however, sufficiently severe in the time of Canute; when the hunting or coursing a royal stag until he panted, by a *freeman*, was punished by the loss of his liberty for one year, and if he was a bondman he was outlawed.

The Conqueror, however, made the death of a beast a capital offence, for which there was no atonement but the death of the offender; while the murder of a man could be commuted for a moderate fine; and, amongst other punish-

ments for offences against these laws (which were repealed by Richard I.) were castration, loss of eyes, and cutting off hands and feet. It is somewhat singular that the son should be slain in the pursuit of deer in the very district which it is said his father had depopulated for their accommodation and increase.

But the real circumstances of the death of Rufus are involved in some obscurity, as several of our early historians say not a word of any tree being accessory to his fall: tradition, however, has even pointed out the oak against which the arrow glanced that was shot by Tyrrell; this tree, formerly standing at Canterton, near Stony Cross, a little to the north of Castle Malwood, noted also for its premature vegetation, like the Cadenham Oak, whose buds appear every year in the depth of winter, had become so decayed and mutilated, eighty years ago, that the late Lord Delaware, to preserve the remembrance of the spot, had a triangular stone erected about five feet high, with the following inscription:—

“Here stood the oak tree on which an arrow, shot by Sir Walter Tyrrell at a stag, glanced and struck King William II. surnamed Rufus, on the breast, of which he instantly died, on the 2nd day of August, in the year 1100.

“King William II. surnamed Rufus, being slain, as before related, was laid in a cart belonging to one Purkis, and drawn from hence to Winchester, and buried in the cathedral church of that city.—[Purkis’s descendants, and of the same name, lived not long ago (and may do still) close to the spot in a neat cottage, and followed the trade of their ancestor, that of a charcoal maker; and, according to the traditional report of the country, have never been rich enough to keep a *complete team*, nor poor enough to apply for *parish relief*, since the event, thus commemorated, took place.]

“Anno 1747. In order that an event so memorable might not be hereafter unknown, this stone was set up by John, Lord Delaware, who had seen the tree growing in this place.”

Two of William’s sons and one of his grandsons were, by uncommon accidents, killed within the bounds of New Forest, viz. Richard by a *pestilent air*; William Rufus by an arrow; his grandson Henry, son of Duke Robert, by hanging in a *rough* after the manner of Absalom.

The ardour of the great Norman lords for hunting kept pace with that of their

monarchs; and the same tyrannic severity against the unfortunate violater of the game, was exercised by these mighty hunters on their own estates, which the king practised against the trespassers on his demesnes.

“In these days (says an ancient writer) our nobility esteem the sports of hunting and hawking as the most honourable employments, the most exalted virtues; and to be continually engaged in these amusements is, in their opinion, the sum of human happiness. They prepare for a hunt with more trouble, anxiety, and cost, than they would for a battle, and follow the beasts of the forest with a greater fury than they would their enemies; by being constantly engaged in this savage sport, they contract habits of barbarity; lose, in a great measure, their feeling and humanity, and become nearly as ferocious as the beasts which they pursue. The husbandman is driven, together with his innocent flocks and herds, from his fertile fields, his meadows, and his pastures, that beasts may roam there in his stead. Should one of these potent and merciless sportsmen pass your door, place before him in a moment all the refreshment your habitation affords, or that can be purchased or borrowed in your neighbourhood, that you may not be utterly ruined, or perchance accused of treason.”

Matters have very much altered since this period as the following anecdote will shew. It is well known that the late king (George III.) was fond of stag hunting; and, on one occasion, the chase led him to ride over a gentleman’s inclosure, who happened to be walking there. The gentleman, with a commanding tone, accosted the king with—“Stop! Sir, this is not a patent path!” His majesty, not accustomed to such a mode of salutation, instantly replied with some emotion, “Do you know who you have, Sir?” “Yes (rejoined the other) I know that I have the king of Great Britain talking to me, but I am king upon my own property.” It is said, that George III. with great presence of mind, and a frankness that did honour to royalty itself, clapping his hand upon the pommel of the saddle, exclaimed with an air of exultation and pleasure, “I am the greatest king upon earth; for, while other monarchs rule over slaves, I reign over princes.”

But to return to our ancient writer.—He tells us that the fair sex caught the prevailing passion for the chase; while, as we learn from other authors, the *mitre*

deserted its functions, and the *cowl* quitted the quiet retirement of the monastery to join in the infatuating transports of the chase. It is no small matter of surprise to find the clerical character make so conspicuous a figure as it does in all rural sports during the middle ages. But it must be recollected that at this period a cloud of ignorance and barbarism having overspread the greatest part of Europe, such ranks of society as were removed by their riches or profession from the necessity of labour, could only amuse themselves with hunting, hawking, and other exercises that required but little mental exertion. Ecclesiastics, in particular, separated as they were from secular cares, had more time on their hands than any other description of people; a leisure they seem chiefly to have employed in the joys of the chase.

Walterus, Archdeacon of Canterbury, who was promoted to the see of Rochester in 1147, spent the whole of his time in hunting, utterly neglecting the high duties of his office. He lived to a very advanced age, and was, when eighty years old, as keen a sportsman as ever. Reginaldus Bryan, translated to the Bishopric of Worcester in 1352, was another episcopal Nimrod. In a manuscript epistle of this prelate, now extant, written to the Bishop of St. David's, Reginald reminds the father of a promise he had made, to send him six couple of excellent hunting dogs; the best (the mitred sportsman confesses) he had ever seen. These, he tells him, he had been in anxious expectation of every day; and he declares his heart languished for their arrival.—“Let them come then (says he) Oh! Reverend Father! without delay; let my woods re-echo with the music of their cry, and the cheerful notes of the horn; and let the walls of my palace be decorated with the trophies of the chase!” Nor were these clerical sportsmen content with consuming their leisure time in amusements of this nature; they even contrived to blend them with the functions of their office; and in the visitations and progresses which they made at particular periods through their dioceses, such numbers of hounds, horses, huntsmen, and falconers, swelled their retinue, that the religious houses in which they were pleased to quarter themselves were frequently much distressed to provide for so large a company. About the year 1200 the prior and canons of Bridlington in Yorkshire, presented a formal complaint

to Pope Innocent III. against the Archdeacon of Richmond, who, when he made his visitations, brought so many horses, hawks, and attendants with him, that the complainants declared his motley suite destroyed more provision in one hour than the whole community consumed in a long time. The Pope, in answer to the petition, dispatched a bull, directed to the Archbishops, Bishops, and Archdeacons, Deans, and Officials of York, forbidding such shameful and oppressive visits in future.

The monasteries also afforded no less notable hunters than the episcopal chair. William de Clowne, whom his biographer celebrates as the most amiable prelate that ever filled the Abbacy of St. Mary, in Leicester, numbered amongst his excellent qualities, a profound skill in the science of hunting. That his kennel might be always well supplied, he requested the king (Richard II.) to grant him a market or fair, for the sole purpose of buying and selling hounds; which request, the king, seeing he passionately desired it, complied with. This Abbot (observes his eulogist) was esteemed the most famous and knowing sportsman in the pursuit of the hare throughout the whole kingdom; insomuch that the king himself, prince Edward, his son, and most of the grandees of the realm, allowed him annual pensions, as a return for the instructions he gave them in this species of venery.

The Anglo Saxons pursued the chase on foot; and their objects of pursuit appear to have been principally the wild boar and the wolf; the Anglo Normans might be considered as more polished, more noble, and more scientific hunters: they introduced that powerful and pleasant assistant in the chase, the horse, as well as a great variety of objects of pursuit. They chased the stag, the roebuck, the fox, the hare, &c. and hunting the less dangerous animals seems to have constituted their principal amusements; though the wolf and the boar occasionally occupied their attention.

They had two modes of following field sports; one of which (that usually pursued) was the following:—The king or baron, attended by a numerous retinue, mounted his horse, and rode to the spot which had been previously marked out for the sport of the day. Here the great man and his favourites took their stations in places by which it was supposed the game would pass: the attendants separating, dispersed

themselves through the forest, and rousing the deer, endeavoured to drive them to these fatal spots. As the animals glided by, the sportsmen discharged their arrows at them; and being in the constant habit of using their weapons, they became such expert marksmen that their bows seldom twanged in vain.

Little different from the sport just described, but attended with more ceremony, was the diversion named the *Traist* or *Trista*, which is thus described:—A wide and extensive plain was sought out, surrounded entirely by a wood, which was barricaded on all sides, except certain openings in particular spots for the ingress and egress of the game. A mound or eminence was raised, if there was no natural knoll in this area, in such a situation as to command a view of the game, and give the person an opportunity of discharging his arrow at it. Here the king stood; the beasts were then driven into the area, and the dogs sent after them; and such as passed by the ambushed monarch could not of course escape the chance of being destroyed by him. Those which attempted to escape through the openings before mentioned, were torn down by the dogs, or intercepted by the attendants stationed there for the purpose.

Though the old English ladies seem to have been somewhat partial to a sport which so deeply engaged the attention of their husbands, yet they generally practised it in a style suitable to the delicacy of their sex. They rode in a chair or litter, either carried by men, or borne by a horse, and were content to watch the motions of their masculine companions rather than take an active part in the chase. Yet the ladies, prior to the time of Richard II. when they rode on horseback, did not make use of the side-saddle; but like the Italian females of the present day, (as well perhaps as other parts) they bestrode the animal in the same way as men. It was to the wife of Richard II. styled by the people “the good Queen Ann,” that the ladies are indebted for the introduction of the side-saddle.

It was some time before the horse became general in the chase; though, in Chaucer’s time, riding in the chase appears to have been the general custom.

The unfortunate John, amidst all the troubles of an inglorious reign, found frequent opportunities of indulging an extreme passion for the chase. The *fine* rolls of his reign sufficiently prove his pre-

dilection for hunting, since, by these documents, he appears to have generally taken, in lieu of those fines which accrued to him, in return for grants and seizin of estates, a variety of dogs, hawks, and horses—animals evidently calculated to indulge and gratify his ruling passion. Edward I. also may be justly enumerated among the old royal hunters of England; as appears from the several items in his wardrobe book (for the 28th year of his reign) of the expenses incurred on this account. He seems, too, to have been one of the original fox-hunters; but his pack would have made but an insignificant figure in the kennel of a modern sportsman, as twelve hounds were the amount of it, and twenty-three pounds, seven shillings, and one penny, the annual expense of keeping them.

So partial, indeed, were our forefathers to the fascinating amusement of which we are speaking, that they considered it as one of the greatest and most serious employments of their lives, and reduced the diversion of hunting to a regular science. Several treatises were written on this subject for the instruction of juvenile sportsmen; and numerous rules were laid down for the observation of those who filled the various offices in the forest, the kennel, and the stable. One of the most curious performances extant on the subject of hunting, is a manuscript written in the beginning of the fourteenth century, in Norman French, by William Twice, grand huntsman to Edward II. An ancient translation of it into English occurs among the Cottonian manuscripts.

But perhaps, after all, nothing can prove so clearly the partiality of the old English to the sport of hunting, and the eagerness with which it was pursued by every rank of people, from the highest to the lowest, as the number of popular ballads and traditional stories on this subject which have reached our times. By these we find that the excessive severity of the forest laws was insufficient to keep the yeomanry of the kingdom from a pursuit which would seem to have had a connexion with their very existence. Many of them, taking advantage of that weakness of the government and relaxed state of the laws which the feudal system naturally produced, retired into the recesses of the large forests, which, at this period, covered a considerable part of the kingdom, formed themselves into banditti, and pursued this favourite sport without restraint, levying occasional contributions on such as wan-

dered near their haunts. But of these sylvan plunderers, none make so brilliant a figure in tradition, as the famed Robin Hood and the faithful Little John. Their deeds are related in the simple measures of numerous songs, which still continue to be the favourite ditties of the vulgar—a proof that *hunting*, the burden of them all, is a subject deeply interesting to the human heart.

That the wild boar was a constant object of sport with the Saxons, and occasionally with the Anglo-Normans and old English, is not denied by any one; but it seems to be a matter of doubt with some, whether the wolf continued to be hunted in this country after the reign of Edgar, the Anglo-Saxon. Hume, citing William of Malmesbury as his authority, asserts, that this era was marked by the extirpation of wolves from England. Our historian, however, seems to have considered the passage in Malmesbury rather hastily. The monk does not say that Edgar actually destroyed the breed of wolves throughout his kingdom, but that he intended or thought to have done it; and in pursuance of this determination, he imposed a tribute on Llwudwall, king of Wales, of three hundred wolves' heads, to be paid to him yearly; which tribute having been sent for three years, was dropped on the fourth, Llwudwall declaring that he could find no more wolves within his realm. But surely it is not to be thence inferred, that the breed was then completely extinct in England and Wales, as there are documents which completely contradict a supposition of this nature, and convince us that the wolf was hunted in this country so lately as the fourteenth century. They are expressly mentioned as beasts of venery in the laws of Henry I. and among those who formerly held by that tenure called *petit serjeanty*, it was very customary to perform the service of hunting and destroying the wolves in different parts of the kingdom. The particular periods, therefore, when the wolf and the wild boar became extinct in this country, in all probability, cannot be accurately ascertained. At all events, wolves were noxious to the flocks in Scotland in the sixteenth century; nor were they utterly extirpated in that country till the seventeenth century, when the last wolf fell by the hand of Sir Ewen Cameron, of Lochail, in the Lochaber mountains, a situation, certainly, which those who have visited Lochaber will easily con-

ceive as well calculated for the fastnesses and final retreat of such ferocious animals.

The roebuck still exists in the Highlands of Scotland, particularly in that part of this rugged country which is in the neighbourhood of Loch Lomond, the property principally of the Duke of Montrose, and that accomplished Lowlander, Sir James Colquhoun.

The Highland chieftains used to hunt with the magnificence of eastern monarchs. It is recorded of Colin Campbell, (surnamed *Jongallach* or the Wonderful,) who lived about the latter end of the fourteenth century, that, on receiving a visit from the O'Neales of Ireland, he burned to the ground his house at Inverary, that he might have a pretence to treat his illustrious guests with a sight of his field equipage.

In 1528, the Earl of Athol (then on a hunting party) entertained the papal legate in a large lofty timber edifice, built suddenly for the purpose, hung with tapestry and silk, and lighted with glass windows. Gardens and ponds surrounded it; and every variety of food was found within to profusion; yet its site was a desert, twenty miles from any inhabited place. The Italian, at his departure, after having expressed his surprise at the entertainment he had received in terms too gross to be repeated, found his amazement redoubled when he saw the pompous palace he had just quitted consumed to ashes in an instant; nor did it lessen when he was told, "that it was the constant habitude of the Highlanders to set on fire in the morning the place which had lodged them the night before!"

In former times, hunting was often the cause of deadly feuds; such was the occasion of the fatal day of Chevy Chase, which, though recorded only in a ballad, may, from what we know of the manners of the times, be founded on truth; not that it was attended with all the circumstances the author of that natural, but heroic, composition, has given it; for on that day neither a Percy nor a Douglas fell: here the poet seems to have claimed his privilege, and mixed with this fray some of the events of the battle of Otterbourne.

In descriptive poetry of the earliest date, hunting is frequently alluded to; even in the most important action of the whole Iliad, the death of Hector, the pursuit of him by Achilles is thus introduced:—

"As through the forest, o'er the vale and lawn,  
The well-breathed beagle drives the flying fawn,  
In vain he tries the coverts of the brakes,  
Or deep beneath the trembling thicket shakes,  
Sure of the vapour in the tainted dews,  
The certain hound his various maze pursues."

POPE.

We have already slightly noticed the hunting establishment of Edward I. From the account of the comptroller of his wardrobe, A. D. 1299 and 1300, translated at the charge of the society of antiquaries, we are furnished with the items of expense, as well as the style, of a fox-hunting establishment, something more than five hundred years since:—

£ s. d.

Paid to William de Foxhunte, the king's huntsman of foxes in divers forests and parks, for his own wages, and the wages of his two boys, and to care of the dogs from November 20 to the 19th of November following, for 366 days, it being leap year, to each per day two-pence . . .	9	3	0
Paid to the same, for the keep of twelve fox-dogs belonging to the king, for the same time, each dog per day a halfpenny . . . . .	9	3	0
Paid to the same, the expense of a horse to carry the nets from November 20 to the last day of April, 163 days, three-pence per day . . . . .	2	0	9
Paid the same, the expense of the horse from September 1, on which day the hunting season commenced after the dead season, to the 19th of November, 80 days, three-pence per day . . . . .	1	0	0
Paid to William d'Blatherwyck, huntsman of the king's fox-dogs, for shoes for himself and two boys, to each of them two shillings and four-pence . . .	0	7	0
Paid to the same for his habit during the present year . . .	0	13	4
Paid to the same for habits for his two boys, ten shillings each . . . . .	1	0	0
<b>Total</b>	<b>£23</b>	<b>7</b>	<b>1</b>

If this total be multiplied by 15, there will be nearly the due allowance made for the difference in the value of money between that period and the present. Consequently, the whole of Edward's annual expense for this amusement was somewhat more than £350 : 6 : 3 of our current coin; neither was this a trivial charge, if it be considered that this part of his majesty's sporting establishment consisted of only the huntsman, two boys, twelve dogs, and one horse to carry the toils.

Queen Elizabeth was extremely fond of the chase, and very frequently indulged herself in following the hounds; for this reason, the nobility who entertained her in her different progresses made large hunting parties, which she usually joined when the weather permitted. "Her majesty (says Rowland White, in a letter to Sir Robert Sidney, dated Sept. 12, 1600) is well and excellently disposed to hunting; for every second day she is on horseback, and continues the sport long." It is to be remembered, that at this time her majesty had entered her seventy-seventh year. This exercise at so advanced a period of life is a strong proof of her fondness for the diversion. She was then at her palace at Oatlands.

The expenses annually incurred by Elizabeth, on account of hunting, were—

## BUCK HOUNDS.

£ s. d.

Master's fee—whereof to himself, per diem, twelve pence, and the rest to sundry huntsmen serving his appointment . . . . .	50	0	0
Sergeants, two, fee a-piece £20 . . . . .	40	0	0
Yeomen prickers, two, fee a-piece, £9 : 2 : 6 . . . . .	18	5	0
Hounds, and meat to the grooms of the buck hounds, allowances . . . . .	13	6	8
<b>Total</b>	<b>£121</b>	<b>11</b>	<b>8</b>

## HART HOUNDS.

£ s. d.

Master's fee . . . . .	13	6	8
Sergeant's fee . . . . .	11	8	1
Officers and others, serving the said master, wages and allowances . . . . .	13	6	8
<b>Total</b>	<b>£38</b>	<b>1</b>	<b>5</b>

## HUNTING HARRIERS.

£ s. d.

Master of the harriers' fee . . . . .	11	6	0
---------------------------------------	----	---	---

# C H A

	£	s.	d.
Yeoman's fee . . . . .	6	0	0
Officers and others, serving under the same master, wages and allowances . . .	79	1	8
Total	£96	7	8

## OTTER HOUNDS.

	£	s.	d.
Master's fee . . . . .	13	6	8
Grand Total	£269	7	5

In the succeeding reign, when that poor driveller, James I. swayed the sceptre, the expenses of the hunting establishment were as follow:—

## HUNTSMEN.

	£	s.	d.
To Sir Patrick Bourne, master of the privy harriers, for his fee, £120 per annum, and for keeping one footman, four horses, and twenty couple of dogs, £100 per annum . . . . .	220	0	0
To Thomas Pott, master of the hunt, for his fee, four shillings per diem: for three yeomen prickers, to each two shillings per diem: for one groom, twelve-pence per diem: and for keeping twelve couple of dogs, fifty pounds per annum . . . . .	250	15	0
To Robert Rayne, sergeant of the buck hounds, per annum . . . . .	50	0	0
More to him, as one of the yeomen of the privy harriers, £3 per marsem . . . . .	36	0	0
To Mr. Battle, another of the yeomen, the like fee . . . . .	36	0	0
To Richard Barnard, another of the yeomen, the like fee . . . . .	36	0	0
To Nicholas Cockeine, another of the yeomen, the like fee . . . . .	36	0	0
To Richard Lazonby, master of the Lyam hounds, per annum . . . . .	40	0	0
To Richard Gwynne, groom of the harriers to the prince, thirteen pence per diem, and twenty shillings per annum for his livery . . . . .	20	15	5
To John Waters, yeoman of the harriers to the king, twelve pence per diem . . .	18	5	0

# C H A

	£	s.	d.
To Robert Walker, sergeant of the king's hounds, per annum . . . . .	50	0	0
To Richard Brasse, yeoman of the king's hounds, per annum . . . . .	50	0	0

Grand Total £843 15 5

At this period, it is to be presumed, the expenses of these departments were defrayed from the privy purse; but, in a subsequent reign, the stag-hounds were honoured with a new arrangement, and became a part of the regular crown establishment, having been also further favoured by increased salaries, and other local privileges, during the reign of George III. In the reign of the monarch just mentioned, the salaries were—£2000 per annum to the master; to the huntsman, exclusive of a residence at the kennel, £123; six yeomen prickers, £104 each. These find their own horses, but are annually supplied with liveries, horse-cloths, saddles, and all stable appendages. Lord Maryborough is at present master of the stag-hounds.

The masterships of both the buck-hounds and harriers were abolished; the former, when held by the Earl of Denbigh, in 1772, had a salary of £2000 a year, and the latter, at the same period, possessed by Viscount Bateman, one of £2341 per annum. There were also twelve huntsmen at £60 a year each, and six for the master of the buck-hounds, besides a master huntsman, who was allowed £100 per annum for himself and his horses. The salary attached to the mastership of the stag-hounds was, at that time, only £800 a year; and indeed the three were more in the nature of sinecures, than of a sporting establishment for actual field service. In the last reign (George IV.) the harriers were revived; but with the expenses of the establishment we are unacquainted.

The royal stag-hounds commence hunting on old Holy-rood-day, and the days for hunting are the following Tuesdays and Saturdays, until the first week in May; during the holyday weeks of Christmas and Easter, the hounds hunt the alternate days; and the two grand days of the season are those of Holy-rood and Easter Monday.

There are many hunting establishments at present in England on a much more extensive scale than that of his majesty,

and attended, in all probability, with a greater expense; and yet the most extensive sporting establishment in this country will sink very much in the comparison with those of some parts of the Continent, but which will more properly come under the head of SHOOTING, to which article we refer the reader.

With respect to a received notion among many of the citizens of London, that they have a right to hunt, hawk, and shoot, in Middlesex, &c. arising from the Charter, it must be observed, that in about seven years after King Charles II. had confirmed to the citizens all their liberties and privileges, the qualification Act was made, enacting, "that all and every person, not having," &c. (See the GAME LAWS, under the sub-head QUALIFICATION), and that, in the said Act, there is no reservation or exception in favour of the citizens of London. Indeed, there was a statute under 2 Will. and Mary, c. 8, to reverse a judgment given in the Court of King's Bench against the mayor, aldermen, &c. of London; and by that statute all the privileges which had been forfeited were re-granted and confirmed; but the privileges in question can amount to very little, since no man has a right to enter the grounds of

another against the owner's consent, without subjecting himself to an action for trespass.

On this subject Fitzstephens remarks, that the citizens of London have the liberty of hunting in Middlesex, Hertfordshire, all Chilton, and in Kent, to the waters of Grey.—Stephanides Disc. London. This account differs from the clause in the royal Charters granted to them by Henry I. which runs thus: "The citizens of London may have chases, and hunt, as well and as fully as their ancestors have had; that is to say, in the Chiltre, in Middlesex and Surrey." These exercises were not much followed by the citizens of London at the close of the sixteenth century, not for want of taste for the amusement, (says Stowe,) but for leisure to pursue it. Strype, however, so late as the reign of George I. reckons, among the modern diversions of the Londoners, "riding on horseback and hunting with my lord mayor's hounds, when the *common hunt* goes out." This common hunt of the citizens is ridiculed in an old ballad, published in D'Urfey's Pills to Purge Melancholy, vol. iv. p. 42, from which the three following stanzas are selected:—

Next once a year into Essex a hunting they go;  
To see 'em pass along, O 'tis a most pretty show!  
Through Cheapside and Fenchurch Street, and so to Aldgate pump,  
Each man with 's spurs in 's horse's side, and his backsword cross his rump.

My lord he takes a staff in his hand to beat the bushes o'er;  
I must confess it was a work he ne'er had done before.  
A creature bounceth from a bush, which made them all to laugh;  
My lord he cried, A hare!—a hare! but it proved an Essex calf.

And when they had done their sport, they came to London, where they dwell,  
Their faces all so torn and scratched, their wives scarce knew them well;  
For 'twas a very great mercy so many 'scaped alive,  
For of twenty saddles carried out, they brought home again but five!

The English, from the earliest periods, have been distinguished for their attachment to the chase; and Asser, the biographer of the Great Alfred, mentions with amazement, that the king had his youngest son, Ethelward, taught to read before he made him acquainted with hunting.

An author whom we already had occasion to notice, and whose work was originally published nearly a century ago, on the subject of hunting, makes the following observations:—"Perhaps there is no greater demonstration of the degeneracy of the present age than the neglect and contempt of this manly exercise.—

Those useful hours that our fathers employed on horseback in the fields, are lost to their posterity between a stinking pair of sheets. Balls and operas, assemblies and masquerades, so exhaust the spirits of the puny creatures over night, that yawning and chocolate are the main labours and entertainments of the morning. The important affairs of barber, milliner, perfumer, and looking glass, are their employ till the call to dinner; and the bottle or gaming table demand the tedious hours that intervene before the return of the evening assignations. What wonder then, if such busy, trifling, effeminate

mortals, are heard to swear they have no notion of venturing their bodies out of doors in the cold air of the morning? I have laughed heartily to see such delicate smock-faced animals judiciously interrupting their pinches of snuff with dull jokes upon fox hunters; and, foppishly declaiming against an art they know no more of than they do of Greek. It cannot be expected they should speak well of a toil they dare not undertake; or, that the *fine things* should be fit to work out of doors that are of the tailor's creation.

But it must be confessed there are some Grecians also, some learned Rabbies who shoot out the lip and bend the brow at us *servile, unaccountable followers of dogs and horses*. But these also are full as ignorant of the subject they rail at, as the beaux or ladies. For how can a poor vapoured, splenetic pedant, in night gown and slippers, whose spirits are sunk, and eyes pored out over indexes and common places; whose youth and health have been sacrificed to a distant prospect of vain titles and dignities, to the remote expectation of puffing and coughing out the dregs of life over a velvet cushion; I say, how can such a crazy valetudinarian form a right judgment of a jovial exercise whereof he has no idea? How can *he* speak in the praise of riding over hills and mountains that hardly knows how to sit upon his horse or buckle on his spurs?

The taste of the world is clearly altered. Avarice and ambition have taken possession of the hearts of men, who by nature were qualified for more innocent pursuits: and those manly toils which laid the foundations of prowess and glory in the ancient heroes (such as Hercules, Ninus, Cyrus, Romulus, Tamerlane; William the Conqueror of England, Henry the Fourth of France, &c.) are now exchanged for sophistry and quibbling.

But there is yet a remnant, a small remnant, whose souls are superior to these sordid motives; and to these I address my service."

These observations seem rather overstrained; but they come from a thorough sportsman, of what may now be termed, the old school; and one who had perhaps too great a veneration for the customs of the age which has passed away. Hunting has much improved since his time, and while it may be justly said to give health and vigour both to the body and the mind, it spreads at the same time a general benefit around. As a memorial of attention to sportsmen, and of the hint

conveyed to the farmers of the money brought into circulation for hay, corn, &c. by popular hunts, the following letter from a Nobleman to his agent in Leicestershire, is here introduced.

*St. James's, Oct. 12, 1792.*

"On the 2nd inst. I returned you in a parcel by the mail the notices you sent me to sign. I hope you received them early enough to serve upon my tenants in due time, without inconvenience to yourself. I must desire that all those tenants who have shewn themselves *friends* to the several fox hunts in your neighbouring counties, viz. Lord Spencer's, Duke of Rutland's Lord Stamford's, &c. may have the offer and refusal of their farms upon easy and moderate terms; and, on the other hand, that you will take care and make very particular inquiry into the conduct of those tenants who shall have shewn a contrary disposition, by destroying foxes, or encouraging others to do so, or otherwise interrupting gentlemen's diversion, and will transmit me their names and places of abode, as it is my absolute determination that such persons shall not be treated with in future by me, upon any terms or consideration whatever. I am convinced that land owners, as well as farmers and labourers of every description, if they knew their own interest, would perceive that they owe much of their prosperity to those popular hunts, by the great influx of money that is annually brought into the country: I shall, therefore, use my utmost endeavours to induce all persons of my acquaintance to adopt similar measures; and, I am already happy to find that three gentlemen of very extensive landed property in Leicestershire, and on the borders of Northamptonshire, have positively sent, within these few days, similar directions to their stewards, which their tenants will be apprised of before they take their farms at next Lady Day. My sole object is, having the good of the community at heart, as you and all my tenants know that my sporting days have been over some time ago. You are at liberty to make my determination upon the subject as public as you shall think proper."

That the nobleman in question had taken a very just view of the subject, we have no hesitation in asserting; and, indeed, were it only for the purpose of keeping up and improving the breed of the finest horses in the world, hunting is highly to be commended, and encouraged as warmly as possible.

In concluding this highly interesting article, we have had recourse to our favourite old author, whose writings manifest much playfulness of fancy, as well as numerous indelible indications of good sense. Upon what he calls the *lawfulness* of hunting, he makes the following observations:—"Did I write with a design of increasing our society (of sportsmen) I could nick the business by granting all the objections against hunting; by admitting it to be a *brutish, barbarous, sinful waste of precious time, and a persecution of innocent creatures; contrary to the laws of God and nature.*

Were such a declaration to be found in our Bible, or maintained by a bench of orthodox divines, we should soon unstock the theatres and assemblies, and go nigh to depopulate our gaudy metropolis of its *plus-beau* inhabitants. For the *iniquity* of the thing would recommend it to practice; and any argument of its unlawfulness or impiety would render it more genteel and fashionable. 'Tis impossible to conceive what else could establish the enormities of the present age, or excite in rational creatures such desires as were unknown to our ancestors. Is there any temptation to make choice of the Lord's day for gaming, travelling, and running of races, but the ambition to excel in irreligion and profaneness? What less consideration can induce *Lord Feeble* to keep a mistress which he cannot enjoy; or inflame the heart of the *noble Damon* with lust after his neighbour's wife, when he has one of his own so much fairer and younger? For what reason doth the eloquent *Thraso* lard his declamations with oaths and curses, were it not to demonstrate that he fears not that Being, who has positively declared *not to hold him guiltless*? And why does *Madam Haughty* make it in her articles to be married at midnight, and in a private chamber, did it not approach to the delicious sin of the forbidden fruit?

But it is not my aim to increase our numbers, to the destruction of the game, or to invite into our fraternity of hunters, men who are enemies to virtue. I shall therefore leave such reprobates to their private reflections, and not molest them in running the way after their new inventions. The word I have to say is to my wiser brethren, to satisfy their consciences in the integrity of their doings; and to fortify them with an answer to affected objections against their innocent diversions.

The destruction of ravenous beasts of prey will not be envied us by our most querulous opponents; and for taking the others I need only to mention, the large sovereignty given to Adam and the commission to Noah.

But the cavillers will observe, although it be lawful to hunt and destroy the noxious vermin, and tolerably justifiable to seat ourselves down to a dish of venison; yet is it not a barbarous and cruel diversion to persecute a poor harmless, helpless creature, over hills and mountains, two or three hours together, with a bawling, terrifying cry of dogs at his heels; which makes the fright and astonishment of the animal, a thousand times worse than death itself?

To this the author answers.—The tender hearted Christians who make this objection, should first make it evident that the irrational animals are capable of *fear*. Fear is a human passion, founded on reason, accompanied with it, subservient to it. It was given to man in order to excite his obedience to his Maker; and to put him upon thinking and devising means for his safety and deliverance in time of danger, persecution, or temptation. But to bestow this passion where it must be useless and troublesome, on a creature which has no sense of moral evil, not the least notion of league or society, no thought or precaution (as I shall shew hereafter) to devise means of defence or preservation, is utterly unworthy an all-wise and merciful Creator. Were the irrational animals capable of fear, the hare is the greatest object of our pity; and yet has God made her for destruction? There is something so delicious and attracting in her flesh, that she is the game of every carnivorous animal. 'Tis well known she has many more cruel and mortal enemies than fair hunters; enemies that spare her in no season or circumstance; and were it not for her generous foes of the kennel, she would fall a victim to a more painful and dishonourable death, and perish by inches under the wrankling jaws of kites or ravens, stoats or polecats.

Another objection.—But then it will be urged, that it would be more merciful to the harmless creatures, to take them in a trap, or to shoot them in the forms.

We hunters say the seizing a hare in so base a way is downright murder. 'Tis certainly contrary to the design of the creation; for it is very plain they were made to be hunted, and that hounds have

their beings for no other use or purpose in nature, unless to take them in that delightful manner. The former we behold most exquisitely contrived for flight, swiftness, scent and sagacity: the latter, attracted by the odorous effluvium of her feet and body, with such an impetuous eagerness, and endued with such a particular subtlety to investigate her turns and deviations, that it is hardly a question that the two species were made for one another.

What can be a more convincing instance of God's infinite wisdom, or even of his indulgence to the sons of men, than the formation of this animal (the hare), who naturally flies from creatures she never beheld in her life, makes use of the most refined politics to escape their pursuits (though she cannot foresee whether they are the effects of love or anger,) and yet is forced to leave behind her such particles of matter as betray her flight?—Again, of how nice and curious a texture must be the innumerable pores or pipes of the dog's nostrils, which serve as so many sheaths or canals to convey the said particles to the brains of the beagles, there to animate and put into motion every limb, joint, and muscle of their bodies? How excellent was the hand that furnished these creatures with such tuneful notes to assemble their fellows and give tidings to their masters, with such an amazing art to unravel the various windings of the fugitive, with so relentless fury to pursue her to the death? If this be tyranny, who is the contriver? If this be barbarous and contrary to nature, the Lord of nature must answer for it.

But let us for the present answer for ourselves. Let us allow the objection its intended force; let us be so very generous as to grant that a hare has a full intelligence of her enemies' designs, that she has an idea of pain she never felt, a sense and terror of approaching death, and that she is able to make the same reflection we would ourselves in such a terrible juncture; I say, granting these modest postulatus (and they must be granted, or taken for granted, before the objection has any weight,) I would yet ask the finest gentleman at the opera, the most timorous and tender lady of the court, if they themselves were in the circumstances of the animal they pitied, would they be willing to be surprised by bloody assassins in the dark, and to be shot dead in their beds; or, would they not rather wish the

liberty of flying and hiding for life, with a fair chance to escape their pursuers and prolong their days?

On the benefit derived from hunting, the same author remarks, that the wholesomeness of the exercise is so universally acknowledged that it is a common subject with the poets; who, though their beloved town most plentifully supplies them with matter for their satires and tools for their flatteries, yet, as often as they are inclined to embellish their writings with real praise, or descriptions of any thing beautiful or delicious, are forced to lay their scenes in the country; and though most of those who have undertaken pompously to describe the chase, are as ignorant of their subject as the philosopher who offered to instruct Alexander in the art of war, yet thus far they are all unanimously in the right, in recommending it as *the most healthy exercise in the world*.

'Tis a plain case that gentlemen of fortune and estates will not work to maintain themselves; and it is equally certain that if they will not work, they must play vigorously or die miserably. A man that eats and drinks like an Englishman, and uses no labour, renders above half his muscles useless; his joints turn like old rusty hinges, his glands and strainers are loaded and obstructed with dregs and corruption; his whole carcase becomes a bog or quagmire, and nothing but the gout or some such distemper, can be hoped for to his relief, to drain the crudities and stagnant humours, and prolong a painful, useless life. 'Tis possible, I confess, for some who have naturally strong constitutions, to reprieve themselves a while by periodical bleeding, purging, blistering, vomiting, and issues, quantum sufficit (these, my honest parson calls *the exercises of the three great C's, Cities, Colleges, and Cathedrals*); but how loathsome and detestable is such artificial filthiness! How horrid is the course of driving the excrements through unnatural channels! How foggy, unwieldy, phthisicky, and helpless, are such crazy mortals when the affairs of their families, or the service of their country, demand their application! Nay, what a sluggish, stupid, splenetic, effeminate, insipid posterity may be justly expected from such rotten sources? 'Tis no wonder so many of our ancient families are extinct, or degenerated into milksops. What would be the case, if the decayed blood were not now and then recruited by a jolly, sanguine country heiress?

In past generations, in the times of the Percies, Warwicks, and Talbots, when an English nobility thought themselves not above the use of arms; when they valued themselves on personal prowess; when their principal delights were jousts and tournaments; when they strove to gain the hearts of their ladies by bravely laying their rivals on their backs; when they combatted diseases, as well as open enemies, with shield and broad-sword; when they purified their blood by toilsome marches, by lying in the camp, and sweating under heavy armour:—What feats of arms do we then read of! what personal bravery was in those times to be seen in our worthy ancestors! what hopeful, rosy, jolly branches were seen round their tables!—Such was the certain effect of manly exercise.

Every one observes that the fogs, vapours, or diseases of the body, cast a mist, bias, and poverty on the mind; that the health, strength, and soundness of the former is communicated to the latter; and, consequently, that the only fit person, both for advice and execution, is the lively sportsman. Who so likely to mount a rampart or gain an intrenchment as he whose long practice has been scaling the fortifications of the meadows and inclosures? Who so proper to manage his horse with address and intrepidity in time of action, as he whose trade and occupation are leaping over five bar gates, hedges, and stone walls?

The author continues—What pleasure can there be in riding whip and spur, after a bawling pack of dogs, says my *Lord Tapling*? What satisfaction can be felt in sweating a whole day after a twelve-penny purchase, says the *miser* and *stock-jobber*? What ambition is gratified in the conquest of a hare or the slaughter of a fox, says the *jawning courtier*? These are weighty questions; I desire them, therefore, to accept of these weighty answers. First, here is joy, without guilt or repentance. Secondly, here is a savoury dish, and a stomach to digest it, without lying or knavery. Thirdly, here is ambition indulged without envy, corruption, or servile flattery.

The pleasures of the world consist in imagination, in raising the spirits to a warm expectation; and in gratifying the desires by fruition of the object. Let any man behold with what joy and triumph the hunter returns after a successful chase!—Hearken with what transports he recounts his adventures! See the

gaiety and good nature which shine in his face and season his conversation!

I wish our morose philosophers could once be witness of the gladness I have often diffused through a whole parish by a visit with my cry! Poor fainting puss having in vain made trial of the hills and heath fields, at last ventures to expose her fortunes to the highways and villages. The pack follows with full mouth, making towers and chimneys echo with the tune-ful melody. At the enchanting sound, what single soul does not forget every other call of mammon and the flesh, and (throwing down his book, his tools, or his very prayer book) run out to partake? The thresher, in his shirt and redden fillet, hastily exposes the open barn to the pigs and poultry; the whistling ploughman drops his tune, and leaves his cattle staring at the tumult; and the tailor follows after, slipshod and hatless, with his thread over his shoulder. The schoolboy flies from the hated bellfry to the top of the town; the old women hobble out three steps beyond the door, before they think of their crutches; and even the parson of the parish (though the gravest man alive) mounts the old pacer; and if he can but keep in upon the Canterbury, is so gay and youthful as to join his halloo in chorus with the boys. Such a moment is able to bring him back from sixty to eighteen. I was lately in company of very worthy people, where we had the pleasure of a concert of music; a good hand on the violin, and a young lady sung and played on a very fine harpsichord. 'Tis the fashion for every one to commend; and the most insensible auditor, for fear of discovering his own ignorance, must seem to be in raptures. The Lady performed to admiration; one stared, another talked of angels and the spheres; a third wept, a fourth was ready to drop into a trance: at last, a very honest gentleman that sat in a musing posture, having his ears shaken with a longer and louder quiver than ordinary, looked about and gave me a nod and wink, with this ingenuous remark:—*By jingo I never heard any thing better but a cry of dogs; she draws out her note like my old Towler!* The lady herself was not unacquainted with the attraction of hunting, and (as she told me afterwards) she was more proud of this honest, sincere compliment from Towler's master, than of all the rest she received on the occasion."

That hunting is congenial to health beyond any other exercise, is an incon-

testible truth ; that it is highly conducive to longevity we have now many living instances ; but for an account of some remarkable votaries of the chase the reader is referred to the article SPORTSMAN. We shall close the present article with the following very appropriate lines :—

On my little blood hack, dirt and danger defying,  
 To cover I rattle in hopes of a run ;  
 There flit my cares, as the summer dew's flying,  
 Vanish away from the face of the sun.  
 Yes, the hunt are all met, and the country is famous ;  
 The wind in the south too, the scent should be good :  
 " Come, Philip, now give us a gallop to tame us."  
 " We will if we can, Sir—" Hike into the wood."

Not a skirter among them, but crash they go in it ;  
 " Hark ! Concubine's speaking—yoics ! Concubine, hark !  
 Stand steady, don't head him ; he'll break in a minute ;  
 Tallyho ! there's a halloo ! he's off for the park !"  
 Now the pack in full cry, yonder lawn streaming over,  
 See the deer stand and gaze at the gallant array ;  
 Puss steals from her form at the edge of the cover,  
 Where pheasants keep rising and whirring away.

" Gone away !"—in sad earnest, the purls are commencing—  
 Here a farmer and steed most promiscuously roll ;  
 There a Leicestershire blade, on a glutton for fencing,  
 Takes a bullfinch, and *breaks a buck's* neck in a hole.  
 " My lad ! pull that stake out—whoey ! gently ! ad rat it,  
 (While the mare's in a fidget the man's in a fright)  
 Do just stand aside, Sir, and let me come at it."  
 " Forward ! forward !" my boys ! he's away to the right.

Now across a stiff country, Sir Reynard's departing,  
 The virtue of some of his followers fails ;  
 While steeds who went off furies rampant at starting  
 Have soon scarce a member to wag but their tails.  
 Now they make for yon osiers—he's taken the river,  
 See Conqueror foremost to plunge in the tide ;  
 Slap dash in we gallop, nor care for a shiver  
 Where landing is safe on the opposite side.

" Hold hard !" give 'em time to make out where he went. Here  
 See the veterans eagerly press thro' the throng.  
 Yoics ! Countess and Hesperus carrying the scent here,  
 Who says that these gallants cannot go along ?  
 For yon village he makes, but no cunning can save him ;  
 Now sneaks thro' the homestead in pitiful state :  
 Ev'ry effort is over, *they view him ! they have him !*  
 " Whoo-whoop !" lads, surrounded, he yields to his fate !

Tho' the life blood of beauty with terror may curdle,  
 While brooding o'er risks which the sportsman must run,  
 Now imagine him lying in state on a hurdle,  
 And turns but with sighs from the trophies he's won :  
 Yet when England at tyrants would level defiance,  
 Say, what makes her sons so undauntedly bleed ?  
 'Tis the chase—'tis the study of this noble science  
 Gives spirit, and vigour, and health to the breed.

CHEST is the part of a horse comprehended in the side view, from his withers to the bottom of his ribs near the elbow, at the upper part of the fore arm; and is perfectly understood, when we say, "that horse is well let down, and deep in the chest." If, in addition to this, he is "round in the barrel," he may then be said to have a *good carcase*. To judge well of the chest, it is necessary to come before, and take a front view, if which is broad, and the horse stands wide and firm, it is a proof of strength; but if narrow in the breast (alias the chest) he will not only be very likely to cut before, but to become chest-foundered, if put to any extraordinary exertions.

CHEST-FOUNDERING. A debility in the shoulders, chest, and fore-quarters of a horse, seemingly less understood, and certainly less explained hitherto, than any one disorder or defect to which the horse is incident. Those who have written upon this subject, evidently *echo each other*; as they literally and individually say, "it proceeds from hard labour, whereby the horse becomes surfeited; so that upon the whole, it is no more than a severe cold, and is to be managed accordingly." These are, in fact, the very words of BRACKEN, who precedes it with this remark:—"Most authors agree it is so; giving no opinion of his *own*, beyond its originating in a "severe cold, and is to be *managed accordingly*." He says, "the signs are a staring coat, and heaving of the flanks more than common." That a chest-foundered horse may *happen* to have a *staring coat*, or a heaving of the flanks, from some different or *remote* cause, cannot be denied; but that *either* of them are diagnostic symptoms of chest-founder, no scientific practitioner will ever admit.

A horse said to be chest-foundered, is almost invariably contracted in the breast between the points of the shoulders; becoming narrower there, as if there was a *wasting* of those particular parts. If you put him into a *trot*, he moves his legs one before the other with great difficulty, as if they were internally connected, and prevented farther extension by two latent links of a chain. When pressed to a gallop, the case becomes *instantly* decisive; he labours to get his legs from *under him* without success; a general constriction pervades the whole of his fore parts; and his action may, with much more propriety, be termed *jumping* than galloping.

Although no one author has given a proof he ever bestowed an explanatory

thought, or condescended to transmit a single line, upon the *absolute cause* of this very common defect, yet it by no means seems sufficiently involved in ambiguity, to render fair conjecture, or professional opinion, a matter of the least difficulty. As the disorder is invariably fixed upon those subjects which have done the *most expeditious and constant* work, without having been ever known to affect those who have done little or none; so it is natural to conclude, the intercostal and subclavian muscles must have sustained injury, from the incessant vibrative concussions occasioned by the almost eternal contraction and expansion of those parts, in such labour as horses are put to, who become subject to the misfortune, which partakes much more of oppressed nature than of disease. It should seem, by the great number of horses (decidedly chest-foundered) who experience evident relief, and go with much less pain and difficulty, when they have got warm, that the muscular parts acquire rigidity when in a state of inaction, but expand, and gradually throw off the stricture, so soon as the circulation is increased by action, and perspiration produced; both which subsiding, the previous stiffness returns. Let, however, what will be the cause, (and upon which the best opinions may vary) instances are very rarely if ever known of perfect cure, or complete eradication. Long rest, by either a summer or winter's run, will always be found productive of relief, and sometimes hold forth a deceptive promise of permanence, which very mild and gentle work may continue; but hard riding, long journies, or severe labour, will always produce a relapse.

CHILDERS was distinguished from *four* others in succession of the same name, by the appellation of the DEVONSHIRE, or FLYING CHILDERS, having been the *fleetest* horse ever bred or trained in this kingdom, and said to have ran a *mile in a minute*. The fact, however, was not so; he went the *fourth* of a mile at the rate of a mile in a minute, and beat every horse of his time with ease. He was bred by Mr. Childers; was foaled in 1715; and got by Darley's Arabian, dam (Betty Leedes) by Careless. He covered as a stallion, and was sire of Firetail, Black-legs, Second, Plaistow, Snip, and Commoner; all good runners, particularly the first three; also Blaze, Winall, and Spanking Roger, horses of some note; as well as Lord W. Manner's Poppet, (an extraordinary runner at five years old) Steady,

Fleece 'em, &c. He covered but very few mares, except the Duke of Devonshire's.

BARTLETT'S CHILDERS was likewise bred by Mr. Childers, and was own brother to Flying Childers.

HAMPTON COURT CHILDERS was got by the Devonshire Childers, dam (Duchess) by the Newcastle Turk; and was likewise bred by Mr. Childers.

SMALE'S CHILDERS was bred by Mr. Smale, and foaled in 1726. He was got by Bartlett's Childers; dam by the Byerly Turk.

CHILDERS, commonly called GREY CHILDERS, was bred by Lord Chedworth, and got by the Devonshire Childers; dam by Sir W. Wharton's Commoner.

CHUB. This fish takes its name from the head, not only in our own, but other languages; we call it chub, according to Skinner, from the old English *cop*, a head; the French, *testard*; the Italians, *capitone*; in different parts of England this fish is called *chevin*, *nob*, or *botling*; he much resembles the carp, but is of a longer form; the body is oblong, rather round, and of a pretty equal thickness in the greater part of the slope; the scales are large; the irides silvery; the cheeks of the same colour; the head and back of a deep dusky green; the sides silvery, but in the summer yellow; the belly white; the pectoral fins of a pale yellow; the ventral and anal fins, red: the tail forked, of a brownish hue, but tinged with blue at the end; is altogether a handsome fish; will sometimes weigh upwards of five pounds, but Salvianus speaks of them as increasing to eight or nine. The flesh of the chub is not in much esteem, being coarse, and when out of season full of small hairy bones; the head and throat are the best parts, taking care to have the latter well washed and cleansed from the grass and weeds usually in it. The roe is exceedingly good; and this fish, stewed as carp, will, it is said, deceive an epicure.

The haunts of the chub are in rivers whose bottoms are of sand or clay, or which are bounded by clayey banks (with the exception of their being found in the Esk, a river noted for the crystalline clearness of its waters, flowing over a rocky bottom), in deep holes, under hollow banks, in summer particularly, where shaded by trees, weeds, &c. they frequently float on the surface, and are sometimes in streams and deep waters where the currents are strong: in ponds, fed by a rivulet, they

grow to a large size. They spawn in April, and are most in perfection in December and January, having then very few of the hairy bones before mentioned.

The chub does not afford the angler so much diversion as the trout, from being so dull a fish on the hook, and when once struck becoming soon tired; but he bites so eagerly, that when he takes the bait, his jaws are heard to chop like those of the dog, and having a very wide leather mouth, and his teeth in his throat, there is little danger of his breaking his hold; to fish for him, the angler should have a stout long rod, a strong line (if he uses a reel, he will be enabled the better to fish under bushes) with a yard or more of the best silk-worm gut at bottom, a hook proportioned to the bait used, a swan-quill float, and the line so shotted, eight or ten inches from the hook, as to sink the float to a quarter-of-an-inch above the surface; the same ground-bait is to be used as for the carp, and the hook baited with a sufficient quantity of salmon's roe (boiled a little) to fill the bend properly; this, rightly managed, is a tempting bait. The large ones are to be caught by dibbing, very early in a morning, with the brown beetle, or cockchafer: by day-break the angler should be at the river; and after baiting his hook, let him move it two or three times near the surface, as in the act of flying; then let it drop on the water, shaking the rod gently, which will cause the appearance of its struggling to escape; this attracts the chub, who are so fond of this bait, that they will rise two or three at a time to seize it; the landing-net in this fishing should never be forgotten, as the places most likely for success in taking chub are those where the angler cannot get to the water side to land them with his hands.

Another way of dibbing is in a hot summer's day with a grasshopper. In any hole where they haunt, many of them will be seen basking themselves near the surface; the rod must be both long and of considerable strength; the line strong, and in length about a yard: bait the hook with a grasshopper; and the angler must conceal himself behind some bush or tree, and remain as motionless as possible, (for the chub is so fearful, that the smallest shadow of a bird flying over, or of the rod, makes him sink to the bottom, but he will soon rise again): having selected the largest chub, let him move the rod with great slowness and caution, and drop the bait gently upon the water, three or four inches

FISH. *Plate II.*

CHUB, *p.* 132.

DACE, *p.* 196.

EEL, *p.* 246.

GRAYLING, *p.* 381.

before it, and he will infallibly take it: there is no danger of securing the chub, if allowed play enough before it is attempted to be taken out, being one of the leather-mouthed fishes, wherein a hook seldom loses its hold. In the Thames above Richmond, the best way of using the grasshopper for chub is to pinch off the first joints of the legs, and to fish with it as with an artificial fly. In September, when the weed is rotten, the largest dace are likewise so caught. The chub bites also at cadis, beetles, blue-bottles, and almost any natural or artificial fly that is in season, and will often rise at the red-spinner, when the angler is trying for other fish: black and dun flies made gaudy, and ribbed with gold or silver twist, will succeed in streams. They are bobbed for over bushes, and under hollow banks, where the water can hardly be seen; but they are felt very forcibly when they take. In some counties is used the following peculiar way of dibbing for them, where the still deep holes are in the middle of the river, and too distant from the shore for a rod to reach: a line sufficient, if *all* unravelled, to extend *twice* across the water, but when first began with no longer than from bank to bank, is stretched from two persons on one side to one on the other; at the centre of this line, suspended from it, is a short twine, about a yard long, with a hook baited with a cockchafer or grasshopper: thus prepared, they drop the bait before any chub they prefer; when they have hooked, the person carrying the line in reserve runs it out, whilst the fish is drawn over to the other side; the hook is then fresh baited, the extra line coiled up again to its proper length, and the same method pursued. Many pounds weight are thus taken in an hour.

The chub will take gentles, wasps' maggots, (which must be baked in an oven before used,) paste of fine new white bread, (without being made wet,) worked up in the hand, and tinged with vermilion as near as possible to the colour of salmon's roe: from the hook this paste will not easily wash off, and is a most killing bait; but the best baits for *bottom* or *float*-fishing for this fish, are old Cheshire cheese, (such as without crumbling will mould in the hand,) and the pith from the back bone of an ox, with the outward so carefully taken off as not to bruise the inward skin. At every season of the year the former of these is good; but the latter end of summer, and all the winter, are the preferable times for both. In baiting

with the cheese, put a round lump, the size of a cherry, on a large hook, so as to cover the bend and some way up the shank: fish six inches from the bottom, or in cold raw weather the bait may lie on the ground; but if the hole has not been ground-baited, the depth is immaterial: when there is a bite, the float will be drawn under water; strike immediately, and give him play, holding a tolerably tight line, to keep the fish clear from weeds and stumps, which at sight of the angler he will endeavour to get at for shelter; and if not properly managed, he will break the tackle. In the spring of the year, the chub will take a marsh, or small red worm; in May, June, and July, flies, beetles, snails (the black ones with the belly slit, to show the white); in August, pastes: the large chub will also take minnows, small dace, and gudgeons, angled with in the same manner as for perch; and the latter bait used likewise as in trolling for pike, the hook not so heavy leaded upon the shank; they gorge immediately upon taking the bait: their biting times are chiefly from before sunrise until nine in the morning, and from four until after sun-set in the summer, (some will by chance take at any time of the day, when mild and cloudy); and in the winter the middle of the day is best; remembering that in hot weather they are to be fished for at or near the top, and not deeper than mid-water; and in cold, close to, or upon, the bottom; and that the main point in taking this fish is, the angler's keeping himself out of sight.

**CLICKET.** When the male and female fox approach each other for the purpose of procreation, they are said to be clicketting.

**CLYSTER.** A liquid medicine injected by the anus of an animal, with the assistance of a suitable apparatus.

"Clysters administered to horses, says Mr. Clark, are of greater importance in relieving them from many acute complaints than is generally imagined; and it were to be wished, that, in place of the more expensive cordial drenches, &c. which are but too frequently given in most of these cases, a simple clyster of warm water, or thin water gruel, were substituted in their stead; the latter of which would prove of great benefit, whilst the former too frequently prove hurtful.

Clysters serve not only to evacuate the contents of the intestines, but also to convey very powerful medicines into the system, when perhaps it is not practicable to

do it by the mouth; for, although clysters are only conveyed into the larger intestines, and, perhaps, hardly penetrate into the smaller, still they are extremely useful, by fomenting as it were the latter, and, at the same time, by softening the hardened excrement that is accumulated in the former, and rendering it so soft as to be expelled out of the body, by which flatulencies, or other offending matters, that may be pent up in them, are likewise expelled; besides, by their warmth and relaxing powers, they act as a fomentation to the bowels, and hence may be of considerable service in removing spasmodic constrictions in the bowels, carrying off flatulencies, and in preventing inflammation in the intestines, &c. or, by conveying opiates to the parts affected, give speedy relief in colics, &c.

The use of emollient clysters in fevers is considerable: they act by revulsion, and relieve the head when too much affected; besides, by throwing in a quantity of diluting liquor into the intestines, it not only relaxes and cleanses them, but may be said to cool the body in general; at the same time, a considerable portion of the liquid is absorbed, and conveyed into the mass of blood, by which means it is diluted; and, in particular complaints of the bowels, clysters give almost immediate relief. These remedies, when judiciously prescribed, pass directly to the parts affected, as they undergo little or no alteration from the powers of the body."

Mr. Clark further observes, that, as the diseases of horses are cured on nearly the same principles as those of the human body, the doctrines laid down by physicians for the cure of diseases in the latter, are applicable to horses in similar circumstances; only it ought to be observed, for obvious reasons, that the intestines of horses should always be emptied of dung by the repetition of clysters, which have something stimulating in their composition, *previous* to the administering any particular medicine by way of clyster.

"Nor, continues he, is the use of clysters confined to medicines only; food and nourishment may be conveyed into the system in this way, when a horse is unable to swallow any thing by the mouth. This I have frequently experienced in practice, and supported horses for several days together by nourishing clysters, made of thick water gruel, during violent inflammations or tumours in the throat, till such time as they have been discussed or suppurated." The lacteal vessels, whose

mouths open into the inner cavity of the intestines, absorb or drink up the chyle or nourishment that is produced from the food that has been digested, and convey it into the mass of blood. The same process takes place when nourishment is conveyed into the intestines by the anus or fundament, only the food requires to be so far prepared, broken down, and diluted with water, as to render it fit to be absorbed by the vessels mentioned above.

In administering clysters, it ought always to be observed, that the contents of the clyster be neither too hot nor too cold, and only milk-warm, as either of these extremes will surprise the horse, and cause him to eject or throw it out before it has had time to have any effect. Previous to introducing the clyster-pipe, the operator, after anointing his hand and arm with oil, butter, or hog's lard, (observing, at the same time, that the nails of his fingers are short,) may introduce it into the rectum, and draw out the hardened dung gradually. This operation, in farriery, is termed *raking*, or *back-raking*, and becomes the more necessary, as it frequently happens that great quantities of hardened dung are collected in the rectum, and which, in some cases, the horse cannot void easily without assistance of this kind.

The composition of clysters (as Mr. Clark very properly observes,) should be extremely simple. On that account they will be easily prepared, and as easily administered, if the operator is provided with a suitable instrument for the purpose. The generality of clyster-pipes that are commonly used are by far too small and too short: although it may appear a kind of paradox, yet it is a fact, that a clyster-pipe of a larger size than the ordinary ones, and of a proper thickness, is much easier introduced into the anus than one that is considerably smaller. It is likewise obvious, that, when the pipe is too short, it renders clysters of no use, because it cannot convey them so far up into the intestines as is necessary to give them any chance of being retained: a small short pipe, of six or eight inches long, is not capable of conveying the injection to the end of the rectum, which, in a horse of a middle size, is about sixteen or eighteen inches long. In giving injections with these short pipes, the clyster is apt to flow out at the anus, in proportion to the force with which it is injected from the bag or syringe; and this must always be the case, especially if the horse's bladder should happen at the time

to be full of urine, which frequently occurs from its being retained there by the hardened dung in the rectum, which presses the neck of the bladder, and thus prevents the horse from staling.

It happens farther, that, after the hardened dung is taken out of the rectum by the operation above mentioned, the bladder, being distended and full of urine, cannot exert its contracting power immediately, so as to expel its contents. It therefore presses up the empty rectum, and forms, as it were, a kind of tumour in it; and, if the pipe is too short, it cannot reach beyond the rising in the rectum, which forms, as it were, a declivity back towards the anus; and hence the liquor flows back as soon as it is discharged from the pipe, instead of passing forward.

The smallness of the bag or bladder containing the clyster, which is generally proportioned to that of the pipe, is another very material objection to this small apparatus, as it seldom contains one quart of liquid; from which circumstance very little benefit can be derived from the use of clysters in such large intestines as those of a horse. Dr. Bracken, in his first volume, has this very judicious remark on the use of clysters: he observes, that the colon of a horse seems to be three guts, by reason of the two necks of about half-a-yard each, drawn up into many cells or purses, by means of two ligaments, one of which runs along the upper, and the other the under side of it, which, with the assistance of a valve or flap at its beginning, hinder the excrements either from returning back into the small guts, or falling too soon downwards, before the chyle or milky substance prepared from the food be taken into its proper vessels. And, indeed, the cæcum, or blind gut, which is the first of the three larger guts, seems to be so contrived, in the manner of a valve, to hinder the aliment and chyle from passing too soon into the colon; for, if the aliment and chyle were not in some measure hindered in their passage through these large guts, the body could not be sufficiently supplied with nourishment.

The first of these colons is about a yard and a half in length, the second about a yard, and the third, or that part which joins the rectum, near six yards in length; so that the colon of a horse fourteen hands high may be said to be nearly eight yards and a half long; and, from it, along the rectum or straight gut, to the anus, where the excrements are discharged, is not above half-a-yard; so that it is plain clys-

ters operate mostly in the colon, though generally they are given in too small quantities; for what signifies two quarts of liquor in a gut nine yards long, and four or five inches diameter, in a natural state? but, in a colic, it is so distended with flatulencies, that its diameter exceeds seven or eight inches, as Mr. Clark has observed in those dying of that distemper.

Large metal syringes are frequently used for the purpose of giving clysters; but, of all the instruments ever invented, Mr. Clark thinks, these are the most improper for horses. The shortness and smallness of their ivory pipes are not only a material objection, as has been observed, but they are apt to tear and wound the gut; for, if a horse should prove restless, either from pain, as in cases of the gripes, or from viciousness, the syringe and pipe being quite inflexible, in the struggle to throw up the injection, the gut may be wounded, by which a discharge of blood and other bad consequences may follow. But, although there were not the least chance either of their hurting the horse or wounding the gut, yet the force with which they throw up the liquor, always causes a surprise, and, of course, a resistance, attended with a vigorous effort to throw it out, which indeed frequently happens before the pipe of the syringe is withdrawn, and frequently upon the operator.

The instrument Mr. Clark prefers, for the purpose of giving clysters, is a simple bag or ox-bladder, which will hold two or three quarts, tied to the end of a wooden pipe fourteen or fifteen inches long, one inch and a half diameter where the bag is tied, and becoming gradually taper to the extremity, where the thickness should suddenly increase, and be rounded off at the point as smooth as possible. The hole through the pipe may be made sufficiently large, so as to admit the end of a common funnel, for pouring in the liquor into the bag. By the flexibility of the bladder at the end of this instrument, no danger can happen to the horse; whilst the clyster is conveyed so far up into the intestines, that it will be retained. It causes no surprise (provided the liquor be neither too hot nor too cold, but about the warmth of the intestines themselves), as no other force is required to throw it up than the holding the bag a little higher than the level of the pipe; by which means the liquor flows gently into the gut, without any surprise to the horse. After using

the bag, it may be blown full of wind, a cork put into the pipe, and hung up in some dry place, to prevent it from rotting; by which means it will be fit for use on future occasions.

Clysters are distinguished by different names, which denominate the quality of the ingredients of which they are composed, as emollient, laxative, diuretic, anodyne, &c. As the more general use of clysters, in the practice of farriery, would be attended with the most salutary effects, especially in acute diseases, where the speediest assistance is necessary, Mr. Clark subjoins the following forms for composing them, together with the cases in which they may be administered with advantage.

#### EMOLLIENT CLYSTER.

Take of thin water-gruel, 2 or 3 quarts.

Olive oil, 6 oz.

Coarse sugar 6 oz.

Dissolve the sugar in the water-gruel, then add the olive oil.

#### LAXATIVE CLYSTER.

Take of thin water-gruel, 2 or 3 quarts.

Glauber's salt, 8 oz.

Olive oil, 6 oz.

When Glauber's salt is not at hand, common salt may be used in its stead.

A great variety of recipes might be added for making clysters, composed of the infusion of different herbs, seeds, &c.; but, as the above ingredients are always easily got, they will be found to answer all the intentions required under this head, which is to soften the hardened excrements, to lubricate the intestines, and, by exciting a gentle stimulus, promote a free discharge of their contents, which, when once obtained, seldom fail of giving relief in inflammatory cases, spasms, &c.

#### PURGING CLYSTER.

Take two ounces of senna.

Two quarts of boiling water.

Infuse the senna, and having strained the liquor off, then add

Syrup of buckthorn, 4 oz.

Common oil, 4 oz.

This clyster will operate more briskly than the former; and, on that account, may be preferred when an immediate or speedy discharge is necessary.

#### ANODYNE CLYSTER.

Take of the jelly of common starch, or of an infusion of linseed, one pint.

Tincture of opium, one ounce, or about two table-spoonfuls.

When there is reason to apprehend inflammation in the bowels, solid opium may be given in place of the tincture,

from twenty to thirty grains, in proportion to the urgency of the symptoms. It ought, however, to be well triturated or rubbed in a mortar, with a little of the liquid, till it is thoroughly dissolved. The smallness of the quantity of liquid here recommended, gives it the better chance of being the longer retained, as the good effects to be derived from the opium depend entirely on this circumstance. This clyster is proper to be given in violent gripings, attended with purging, in order to blunt the sharpness of the corroding humour, and to allay the pain usual in such cases. The starch will also in some measure supply the deficiency of the natural mucus, or covering of the intestines, which has been carried off by violent purging. It may be repeated, if the symptoms continue violent, only diminishing the quantity of laudanum, or of the opium.

#### NUTRITIVE CLYSTER.

Take of thick water-gruel, well boiled, three quarts.

When nourishing clysters are found necessary, they may be given four or five times in the day, according as circumstances may require. They are of considerable service in cases where the horse cannot eat sufficiently to support himself, nor swallow any thing, from inflammation of the throat, jaws, &c or in convulsions, attended with a locked jaw, &c. Perhaps milk-gruel might be substituted with advantage.

#### DIURETIC CLYSTER.

Take of Venice turpentine, two ounces; Castile soap, one ounce.

Dissolve the soap in two quarts of warm water, then add the turpentine, previously well beaten up with the yolks of two eggs.

Mr. Clark says, this diuretic clyster is of great use in the strangury, and in obstructions of the urinary passages. As it is immediately applied to the parts affected, it seldom fails of giving relief, and has a much better effect, when prescribed in this manner, than when given by the mouth; because it then mixes with the whole mass of fluids, and may lose a considerable portion of its diuretic quality before it reaches the kidneys: but, by being administered in the form of a clyster, it is readily absorbed by the neighbouring vessels, and promotes a free discharge of urine.

It is unnecessary to multiply formulæ for clysters, which are given by most of the modern veterinary writers, and have each their share of excellence. We shall

confine ourselves, therefore, to the following forms given by Mr. Denny.

Take of Glauber's salt, four ounces.

Decoction of linseed, three quarts.

Olive oil, half a pint. Mix.

Take of oatmeal gruel, four quarts.

Common salt, four ounces.

Olive oil, half a pint. Mix.

Take of oatmeal-gruel, four quarts.

Barbadoes aloes, one ounce. Mix.

Mr. Clark observes, that there are many cases where clysters may be administered with great success, besides those already hinted at, as in inflammatory fevers, spasmodic constrictions, and colicky complaints in the bowels; in recent coughs, apoplexy, convulsions, paralytic complaints, swelling of the belly, whether from air or from hardened excrements.—They are required also in cases where horses are troubled with worms, as the ascarides, which lodge in the lower part of the intestines; or when botts are observed sticking in the anus, or voided with the dung; in very costive habits, before laxative or opening medicines are given by the mouth; in wounds which penetrate deep into the muscular or tendinous parts, or in the belly, &c.; in inflammation of the eyes, or when the head seems particularly affected; in inflammatory swellings on any part of the body. Clysters composed of mucilaginous substances, as starch, linseed, &c. are also of great benefit in violent diarrhoeas, whether proceeding from natural causes, or from too strong purging medicines given by ignorant farriers.

It ought always to be remembered, that clysters should be repeated frequently, till such time as the disorder for which they are given is either removed or greatly abated. This injunction may be the more readily complied with, as the administering clysters to horses is not attended either with much trouble to the operator, or disturbance to them.

Mr. Clark adds the following caution

with regard to the operation of clysters: It frequently happens, in colics, and other complaints in the bowels, that a horse will dung frequently, probably from pain, &c. but in a very small quantity at once; at the same time, what he passes may appear somewhat soft or loose. In such cases, the practitioner may be told that clysters are unnecessary and superfluous: this, however, ought not to prevent him from prescribing them; as, in such cases, the flatulences which occasion the disorder may be seated in the colon, where the excrements at the same time are extremely hardened; and it frequently happens, that, after the second or third injection, they are discharged in such a quantity, and in such a state, as to surprise those who were just before opposing and deriding the practice recommended. These prejudices every practitioner will have to combat; for he will frequently have as troublesome nurses to deal with as the physicians complain of, and who are no less ready with their impertinent advice.

COAT. The coat of a horse (which the hair is called) is not only an object of sporting exultation when the horse is in fine condition, but, to the judicious and penetrating eye, is in a great degree indicative of the state of health. Nothing will so soon demonstrate the ability, the care and attention of the groom, as the coat of his horse. If the coat is observed to become suddenly rough, standing different ways, with a dusty hue underneath, and the hair to look harsh and bristly upon the surface, the blood is then sizy, and tending to an unhealthy state; the porous system has been collapsed by some chilling exposure to wet or cold; the integument acquires a tightness and rigidity, which, if not relieved, soon displays itself in some slight degree of disease: this may, in general, be prevented by taking away blood, and proceeding upon a short course of antimonial alteratives.

COCKING. Men have long availed themselves of the antipathy one cock shews to another, and have encouraged that natural hatred, for the purpose of producing diversion. The origin of this sport is said to be derived from the Athenians, on the following occasion:—When Themistocles was marching his army against the Persians, he, by the way, espying two cocks fighting, caused his army to behold them. “Behold, these do not fight for their household gods, for the monuments of their ancestors; not for glory, not for liberty,

## C O C K I N G

nor for the safety of their children, but only because the one will not give way unto the other." This so encouraged the Grecians, that they fought gallantly, and obtained the victory over the Persians; upon which cock fighting was, by a particular law, ordained to be annually practised by the Athenians.

The inhabitants of Delos were great lovers of this sport, and Tamagra, a city of Bælotia, the isle of Rhodes, Chalcis in Eulæa, and the country of Media, were famous for their generous and magnanimous race of chickens. It appears they had some method of preparing the birds for battle. Cock fighting was an institution partly political, at Athens, and was continued there for the purpose of improving the seeds of valour in the minds of their youths.—But it was afterwards perverted and abused, both there and in other parts of Greece, to a common pastime and amusement, without any moral, political, or religious intention, as it is now followed and practised amongst us. It appears that the Romans, who borrowed this, as well as many other things, from Greece, used quails as well as cocks for fighting. The first cause of contention between the two brothers, Bassianus and Geta, sons of the Emperor Septimius Severus, happened, according to Herodian, in their youth about fighting their quails and cocks. Cocks and quails, fitted for the purpose of engaging one another to the last gasp for diversion, are frequently compared in the Roman writers, and with much propriety to gladiators. The fathers of the church inveigh with great warmth against the spectacles of the arena—the wanton shedding of human blood in sport. One would have thought that with this, cock fighting would also have been discarded, under the mild and humane genius of Christianity; but it was reserved for this enlightened era, to practise it with new and aggravating circumstances of cruelty.—The Shrove Tuesday massacre is now, indeed, abolished; but that monstrous barbarity, the battle-royal and the Welch-main, still continue amongst us—a striking disgrace to the manly character of Britons.

It is probable that cock fighting was first introduced into this island by the Romans. The bird itself was here before Cæsar's arrival.

William Fitz Stephen, who wrote the life of Becket, in the reign of Henry II. is the first of our writers who mentions cocking, describing it as the sport of school-boys on Shrove Tuesday. The theatre (the cock-pit) it seems was the school, and the master was the comptroller and director of the sport; from this time at least, the diversion, however absurd, and even culpable, was continued amongst us. It was followed, though disapproved and prohibited (39 Edward III.); also in the reign of Henry VIII. and A. D. 1569. It has by some been called a royal diversion, and every one knows the cock-pit at Whitehall was erected by a crowned head, for the more magnificent celebrating of the sport. It was prohibited, however, by one of Oliver's acts, March 31, 1654.

# COCKING

## AN ORDINANCE PROHIBITING COCK-MATCHES.

Fryday March 31. 1654. Ordered by His Highness the Lord Protector, and his Council, That this Ordinance be forthwith printed and published.

HENRY SCOBELL, Clerk of the Council.

*London*, Printed by *William du-Gard and Henry Hills*, Printers to His Highness the Lord Protector, 1654.

Whereas, the Publique Meetings and Assemblies of People together in divers parts of this Nation, under pretence of Matches for Cock-fighting, are by experience found to tend many times to the disturbance of the publique Peace, and are commonly accompanied with Gaming, Drinking, Swearing, Quarrelling, and other dissolute practices, to the dishonour of God, and do often produce the ruine of Persons and their Families: For prevention thereof, Be it Ordained by his Highness the Lord Protector, by and with the advice and consent of his Council, That from henceforth there shall be no publique or set meetings of Assemblies of any persons within *England* or *Wales*, upon Matches made for Cock-fighting; And that every such meeting, and assembly of people for the end and purposes aforesaid, is hereby declared to be an unlawful Assembly, and shall be so adjudged, deemed and taken to be, and punished; And all Sheriffs, Justices of the Peace, Maiors, Bayliffs, Constables, and Head-boroughs, within their several Counties, Cities, Limits, and Jurisdictions, are hereby required to suppress, hinder, and disperse all such meetings and assemblies.

Friday March 31. 1654. Ordered by his Highness the Lord Protector, and his Council, That this Ordinance be forthwith printed and published.

*Henry Scobell*, Clerk of the Council.

There is always a great secret made amongst cock-feeders of their arts of training; being an amateur of the cock-pit, and having seen the management of many different feeders, I am really inclined to deny them the greater part of the merit they would arrogate to themselves. I am convinced that a great deal depends upon breed, and *nearly* all the rest upon the cocks being well walked, and in good condition, both of body and plumage. A well-walked cock will strike harder, and fight, in steel, with more vigour and success when he has been taken from his walk for three or four days, than one that has been ill-walked, but has had all the improvement that feeding can give. For fighting in silver, more trim, exercise, and physic are required.

A very proper and indispensable prelude to feeding of any sort is the breeding up of cocks that will bear such a course of training as they are usually subjected to. Corn of the finest quality and of the

## C O C K I N G

easiest digestion—that which has been housed the ripest, presents itself as the food best adapted to the whole feathered tribe, though the habits of some lead them to devour animal food, fish, and other substances. But what is the condition of such birds? what their propensities? We need scarcely bestow a single thought upon the appropriate answer; and in that answer, will be found the impolicy of bringing up game chickens, as of training game cocks, upon raw meat, according to the general practice (it is apprehended), when worms are obtained with difficulty. Much better would it be to convert the meat into gentles, by means of artificial heat, in the same manner as anglers procure such worms by the heat of the sun and the blowing of flies. For this purpose (seeing that the worms would be mostly required early in the year), some large blow-flies may be put away in autumn, and be raised from the dormant state by heat, so as to impregnate (or blow) animal matter in abundance; nor will they readily leave the genial retreat provided for them, though left at large, if they are sheltered from the action of the boisterous winds that prevail early in the year.

Exercise and good water appear to us primely essential requisites in training cocks; and the walks provided for them should possess the means of obtaining both. As, in attaining the first mentioned, frequent runs will be required, the advantage of a field adjacent would mainly conduce thereto, so also conveniences should be provided for separating the quarrelsome from each other. This latter more especially, since the practice of permitting the stags and younger chickens to spar occasionally, will improve their wind, try their pluck, and reduce the quantity of fat which gathers round the gizzard, the heart, &c. in highly fed animals; besides, that when these bouts are over, if one does not give in, or run under the other, they will be always at it, and must be separated.

Wherever the convenience exists of making a small streamlet of fine clear water, this course should be adopted in preference to using shallow pans that require frequent filling, which soon get muddled by the fowls walking over them, and the readiness of attendants to replace clean water instead, seldom keeps pace with the spoliation and wants of the game animals, which stand in need of much drinking.

### *“ Rules and Orders for Cocking, at the Cock-Pit Royal, Westminster.*

“ On the weighing morning, the person whose chance it is to weigh last, is to set his cocks and number his pens, both main and byes, and leave the key of the pens upon the weighing table (or the other party, if he pleases, may put a lock on the door) before any cock is put into the scale, and after the first pack of cocks are weighed, a person appointed by him that weighed first shall go into the other pens to see that no other cocks are weighed but what are so set and numbered, provided they are within the articles of weight that the match specifies; if not, to take the following cock or cocks,

## C O C K I N G

until the whole number of main and bye cocks are weighed. And after they are all weighed, you are to proceed as soon as possible to match them, beginning at the least weight first, and so on; and equal weights or nearest weights to be separated, provided by that separation a greater number of battles can be made, and not otherwise; and all blanks, that is, choice of cocks, are to be filled up on the weighing day, and the battles divided and struck off for each day's play, as agreed on, and the cocks that weigh the least are to fight the first day, and so upwards.

“ At the time agreed on by both parties to begin fighting, the cocks that are to fight the first battle are brought upon the pit by the feeders, or their helpers; and after being examined, to see they answer the marks and colours specified in the match-bill, they are given to the setters-to, who, after chopping them in hand, give them to the gentlemen who are called masters of the match (who always sit opposite to each other) when they turn them down upon the mat; and the setters-to are not to touch them, except they either hang in the mat, in each other, or get close to the edge of the pit, until they leave off fighting, so long as a person can count forty.

“ When both cocks leave off fighting, until one of the setters-to, or a person appointed for telling the law, can tell forty gradually; then the setters-to are to make the nearest way to their cocks, and as soon as they have taken them up to carry them into the middle of the pit, and immediately deliver them on their legs, beak to beak, and not touch them any more till they have refused fighting, so long as the teller of the law can count ten, unless they are on their backs, or hung in each other, or in the mat: then they are to set-to again in the same manner as before, and continue it till one cock refuses fighting ten several times, one after another, when it is that cock's battle that fought within the law.

“ But it sometimes happens that both cocks refuse fighting while the law is telling; when this happens, a fresh cock is to be hovelled, and brought upon the mat as soon as possible, and the setters-to are to toss up which cock is to be set-to first, and he that gets the chance is to choose. Then the other which is to be set-to last, must be taken up, but not carried off the pit; then setting the hovelled cock down to the other, five separate times, telling ten between each setting-to, and then the same to the other cock; and if one fights and the other refuses, it is a battle to the fighting cock; but if both fight, or both refuse, it is a drawn battle. The reason of setting-to five times to each cock, is, that ten times setting-to being the long law for one cock only, so on their both refusing, the law is to be equally divided between them, as they are both entitled to it alike.

“ Another way of deciding a battle is, if any person offers to lay ten pounds to a crown (that is, if he is a person thought capable of paying when he loses, or one who stakes his money upon the mat) and no person takes it until the law-teller tells forty and calls out three separate times, “ Will any one take it?” and no one does, it is the cock's battle the odds are laid on, and the setters-to are not to

## C O C K I N G

touch the cocks during the time the forty is telling, without either cock is hung in the mat, or on his back, or hung together.

“ If a cock should die before the long law is told out, although he fought in the law, and the other did not, he loses his battle; for there cannot be a better rule for a cock winning his battle than killing his adversary in the limited time he is entitled to by cock laws.

“ There are often disputes between the setters-to, as also with the spectators, respecting their counting the long law, for often both cocks refuse fighting until four or five, or more or less times, are told; then they begin telling from that cock's fighting, and counting but once refused, but they should continue their number on, until one cock has refused ten times; for, when the law is begun to be told, it is for both cocks: for if one cock fights within the long law, and the other not, it is a battle to the cock that fought, counting from the first setting-to.

“ All disputes about bets, or the battle being won or lost, ought to be decided by the spectators; for, if the bets are not paid, nor the battles settled according to judgment then given, it will be good evidence in law, if an action is brought for the recovery of such bets. The crowing and mantling of a cock, or fighting at the setter-to's hand, before he is put to the other cock, or breaking from his antagonist, is allowed no fight.”

The cocking season usually begins about Shrovetide, and has an equal duration with that of racing; races being seldom held without the addition of cock-fighting. There is, perhaps, scarcely a county in England, in which this sport does not prevail in some degree; *but the Cock-pit-Royal*, Tufton-street, Westminster, is the grand theatre. The battles commence there, each night, throughout the season, at a quarter before six o'clock precisely. We have had, in all times, some men of quality and distinction attached to this sport.

The fighting principle is by no means confined to the domestic cock, since other birds partake of it in a proportionate degree; for example, the pheasant and partridge, and even the sparrow and diminutive tom-tit! There is considerable analogy between the sports of the Turf and the Cock-pit. They are both derived from classical antiquity, and have, together, been patronised and practised for centuries, in this country almost exclusively; the chief exception, perhaps, being the native Hindoos, or inhabitants of India, who have, from the early ages, practised this sport with their large breed of cocks. The game-cock, like the race-horse, is a fine-boned, clean-shaped, and symmetrical variety of the species, discovered by man from those outward and visible signs, to be properly adapted to those purposes to which they were consequently applied. Game-fowls and race-horses are kept rigidly apart from commixture with any other variety, since they, being possessed of a peculiar intrinsic superiority, any alien or inferior cross must necessarily have the effect of destroying the integrity of the breed; in fact, of rendering it totally incompetent to its intended purposes. In one respect, there is a difference

of opinion between the cock-walk and the breeding stud. In the former, they make no scruple to breed in and in, that is, from the nearest affinities, putting the game pullets to their own sire.

An *aspirant* after the laurels of the sod and cock-pit, whom, from his natural *penchant* for strife and contention, for battle, murder, and sudden death, we can do no less than dub a *hero* by nature, born to defend his own dunghill,—must adopt the following fundamental rules, if he would insure success and not subject himself to the painful and disgraceful necessity of retracing his steps. Let him seek and practice the best *advice*, provide the best breed of cocks, the best breeders and trainers, (honest, *if* he can find such); and, without sparing any necessary expense in keeping, feeding, and training, let him bring them to the pit at the best age, and in the most blooming condition.

In the days of Charles II. and old Frampton, the get of SOURFACE were all the *ton*. So many new best breeds, that is, fashionable changes of colour succeeded, from that early period to the time from which we can date our first reckoning, that our allotted space would be insufficient for the bare catalogue.

*Black* cocks formerly contended for popular favour awhile, but without success; they have, however, bequeathed the legacy of a portion of their blood to the pit, as is proved by one of the present favourites, the *black-breasted red cock*. This colour has, however, found a rival in the *Norwich or Gurney pied cock*. Both colours have proved successful in country mains, and at the Cock-pit-Royal, in the metropolis. Cocks are *heeled* for battle with steel or silver spurs, and much, or, by chance, every thing, may depend on the judicious fixing of these spurs; a thing to be determined by the mode in which the cock uses his natural weapons. An experienced cocker only, of course, can be *au fait* at this critical business, and his lesson will not be quite learned unless he has witnessed a trial of the cock and his peculiar mode of striking. Young cocks are called *stags*, and the bird is in his prime at two years old. A *Welch main*, in which the survivors continue to fight to the last gasp, until the last have no fellow combatant surviving to do him the final charitable office, must needs glut the most heroic thirst of blood, even that of Cadwallader himself, were he in existence.

COCK-FEEDER signifies a person whose occupation it is to collect, handle, and feed a pen of cocks, to fight such main or match as may be made or agreed on, by those who deposit the battle money, and are called the masters of the match. These find or procure the cocks, of which the feeder takes charge; and to his judgment is submitted the entire management of selecting, rejecting, feeding, physicing, sweating, sparring, weighing, cutting out, (alias trimming,) and bringing his bag and cock to the pit; where, upon delivering it to the setter-to, his function ceases

in respect to that particular cock, till death has sealed his disgrace, or success proclaimed his victory.

COCK-MATCH, an agreement and article entered into by opposite parties, to shew any number of cocks (as twenty-one, thirty-one, forty-one,) on each side in the main, and ten in the byes, to fight for ten guineas a battle, and fifty the odd." The cocks so agreed to be matched, are under the management of their different feeders till the day specified in the article for their being shewn and weighed; which day is, upon most occasions, the

day but one preceding the day on which the main begins to be fought. This ceremony is attended to with the most scrupulous nicety on each side; every cock is weighed precisely to a quarter of an ounce; his colour described almost to a feather; his marks in the eye, the right and left norrel, the in right and out left in the feet, are all taken down in writing, with the same accuracy as the weight; the whole being entered in the match-bills to be produced, read, and compared, with the cocks as they are brought to pit at the commencement of every battle.

The number of cocks having been shewn and weighed on each side, the match-bills, containing their weights, are compared; and all those who are either dead weights, or within an ounce of each other, are said to fall in, and are called main battles; in contra-distinction to those who do not come within the ounce of each other, and are thrown into the byes; which are generally fought for a trifling sum, and have no affinity whatever to the main. Should the cocks, thus falling in, constitute either a very small or an even number, it is usual then to separate cocks of dead weights, or the nearest so, to match against others, (giving or taking an ounce in weight) that the main may be extended in respect to the number of battles, and that number to be odd; thereby preventing, if possible, the mains being undecided; which, indeed, sometimes happens unavoidably by the chance of a drawn battle.

That the match may be the better understood, let it be supposed that A stands engaged with B "to shew twenty-one cocks on each side, ten guineas a battle, and fifty the main or odd battle." Of these fifteen fall into the main; and the remaining six are thrown into byes, and fight for two guineas a battle. It is in such case a custom to fight a part of the byes, both before and after such part of the main as is fought on each day, whether it is finished in one day, or is a long main of many days' duration. The match being concluded, we find A has won nine main battles and two byes; B six main battles and four byes; when the winning and losing will stand precisely thus: A having three battles ahead in the main, is a winner of fifteen guineas upon the single battles; and winning the main also, he wins the twenty-five guineas upon that event; making himself the creditor for forty guineas: but in the byes, B having the advantage of four battles to two won

by A, affords him a drawback of two guineas; and B is the loser of thirty-eight guineas battle-money upon the whole match; it being remembered, the byes were fought for only two guineas a battle; or, in other terms, a guinea each cock. And this it will be necessary for young adventurers to remember, that a match made for "ten guineas a battle," is tantamount to five guineas each cock; and "fifty guineas the odd of the main," is always *bona fide* understood a deposit (if required) before fighting of five-and-twenty guineas aside.

Cocks of middling size, and adequate powers, are always considered the sharpest and best fighters; in confirmation of which opinion, custom has established the match weights from three pounds six ounces, to four pounds eight; none to be shewn and weighed in the main under the former, or above the latter, unless an extension to either a lower or a higher weight should be agreed on by the parties. Sometimes (but very seldom) a short match, of a different kind, takes place, and is termed a "shake-bag" match, (or battle); which is no more (the battle money having been previously agreed on) than "turning the cock out at the bag's mouth" in the pit, to meet his opponent, without ever having been brought to the scale, or the weight of his adversary ascertained.

In weighing the cocks, and making the match-bill, it is an invariable rule to begin with the lightest pair, who are to fight first, and so continue according to their weight upwards; such successive pair being heavier than the former, so that the heaviest pair of cocks are fought the last. Various sums being betted upon a match (or main) soon after it is made, it may not be inapplicable to observe, that those who lay the odds in any proportion, as five to four, six to four, two to one, (or whatever odds may be laid,) either upon the main or a single battle, is always entitled to the privilege of choosing his side, although it may not be mentioned; and this right he is possessed of in consequence of laying the odds.

**COCKPIT.** A place appropriated entirely to the purpose of cock-fighting, for which it is erected: it is usually of an oblong or circular form, surrounded with seats, to which the spectators pay for admission; and, in great mains, or subscription matches, the feeders generally agree with the masters of the match, to receive the whole of this door money, (equally

divided between them,) as their compensation for the fortnight or three weeks they are engaged in feeding the cocks.

At the hour previously agreed on, the bags containing the cocks are brought into the pit by the feeders, or whoever they may appoint: they are there received by persons called the setters-to, whose qualifications depend upon a quick eye, a light hand, and agile heel; without the whole of which, celebrity can never be acquired in their way. The cocks being taken from the bags, are most scrupulously compared in feather and marks with the original description entered in the match-bill on the day of weighing; if there should prove the most trifling deviation from which, a mistake, wilful or accidental, is supposed to have taken place, and no progress whatever is made in fighting, till it is completely rectified, and the cause done away. This scrutiny is seriously critical, and made by the feeders, who attend minutely to the match-bill and marks of each other's cocks; which ceremony gone through, and admitted to be right, the feeders retire from the centre of the pit, becoming spectators; and the setters-to are then the sole possessors with the cocks in hand. In this state they are shewn to each other "beak to beak;" and if they "show fight," they are (for form's sake in the first battle only) given into the hands of the makers (called masters) of the match, who are situate in the lowest circular seat opposite to each other, and they giving the cocks a set-to toss upon the mat, the battle begins amidst clamours indescribable, and offers of bets innumerable, according to the pecuniary sensations, opinions, and predictions of the different parties interested in the event, constituting a scene very far beyond the power of description, and which must be seen to be perfectly understood.

There are certain rules and laws of custom to be observed in fighting; the most material of which it is necessary to explain. When once the cocks are pitted, neither of the setters-to have the privilege to touch or handle his cock, so long as they continue to fight, unless their weapons hang in the mat, they are entangled with each other, are got too close to the edge of the pit, or have left off fighting while the umpire or law-teller can count forty; when, in either of these cases, each setter-to instantly handles his cock, bringing them beak to beak in the middle of the pit: if one cock has refused to fight

while the telling forty took place, his adversary, who made the last fight, with either heel or beak, is said to have the first law in his favour. When brought beak to beak, and set on their legs, if the cock who did not fight while the forty was telling, continues to decline fighting, the setter-to of his adversary (or umpire, if there is one) proceeds to tell ten; which being done, they are again handed, and brought beak to beak; if the same cock continues still unwilling or unable to fight, the ceremony of telling ten, and bringing beak to beak, at the conclusion of every ten, takes place, till it has been repeated ten different times, when the cock so refusing to fight has lost his battle. But should he fight during any part of the law, (even in telling the last ten,) what has been told is of no effect, and the first ten must be begun again, whenever a fight is renewed. Instances sometimes happen, when the cock who has the long law in his favour, retreats from the cock seemingly beaten, and in his turn has the law going on against him; so that the cock who fights last has the law in his favour, till one side or other is counted out.

If, during a battle, (either by long fighting or a cut down blow,) any person offers to bet ten pounds to a crown, or throws his hat, glove, or handkerchief, into the pit, which is the same thing, and so understood, though not a word is spoken, the teller immediately begins to tell forty in a deliberate manner, which being done, he proclaims, "ten pounds to a crown is betted; will any body take it? will any body take it?" No reply being made, the battle is won by the cock upon whom the odds were offered. On the contrary, should the bet be accepted in words, or a handkerchief, hat, or glove, be thrown into the pit, during the time of so telling the forty, it is an acceptance of the ten pounds to a crown offered, and the cocks are instantly handed, beak to beak, in consequence. If a cock, having the law in his favour, dies before the long law is told out, his adversary wins the battle, although he did not fight within the law; for there cannot be a greater criterion of victory, than having killed his opponent.

When the cocks are first shewn in the hands of the setters-to, and either refuses to face, that is, to fight, it is deemed no battle, upon the equitable principle, that no man can lose where he has no chance to win. There are frequently disputes

between the setters-to respecting which cock is in for the law in his favour, during the changes which sometimes happen in setting-to during the process of telling the long law; as well as disputes amongst the spectators concerning bets made, and misunderstandings during the heat of battle; to prevent litigation, and long-standing animosity, it is an invariable rule, that all disputes are to be decided by a majority of the pit; but in all pecuniary altercations, both parties deposit their money before the question is asked, in proof of their readiness to acquiesce in the decision when made. Persons making bets in a pit, which they were afterwards unable or unwilling to pay, were formerly drawn up in a basket by pullies, and suspended during the play; that ceremony, however, is now altogether dispensed with, the aggressor being instantly turned out of the pit, with a variety of cuffs and kicks plentifully bestowed upon him in the gauntlet of his escape.

**COCK'S WALK** is the place to which a game cock is removed, from the place where he was bred, (and where he walked under his sire,) to the spot where he is to remain till taken up to fight; this is called his walk, of which he is the master, not walking under any other cock. They are commonly sent out to walk at six or seven months old, previous to which they have their combs and gills taken off, and are marked in the eyes, norrils, and feet.—At this age they are called chickens; when turned of a year old, they are termed stags; and at two years old, cocks.

**COFFIN-BONE.** This bone is situate at the lower extremity of the foot, deposited in the membranous mass with which the box (or coffin) of the hoof is lined, and is in nearly the shape of the hoof itself: in the centre of the coffin-bone is a concavity, into which is inserted the inferior part of the coronary bone, supported by the nut bone behind: upon the superior part of the coronary bone (that is just above the line said to be “between hair and hoof”) is lodged the lower part of the fetlock bone, its upper part articulating with the fetlock joint.—Injuries are very frequently sustained by holes in the road, or cavities in the pavement, into which a part, or the whole, of the foot getting, ligamentary twists or distortions happen to the lower joints. Too much pains cannot be taken in accurately ascertaining the exact seat of lameness, particularly in these parts, as a great number of horses are annually blistered

and fired by much too hastily, and upon parts where no lameness has ever been.

**COFFIN-JOINT**, the joint situate below the fetlock, and just above the union of hair and hoof; this is the part universally known by the term coffin-joint; but, in fact, it is not in reality so; for this being formed by the upper part of the coronet with the lower part of the fetlock-bone, leaves the whole coronary bone between the spot described and the coffin-bone. The coffin-joint is buried in the body of the hoof, and is formed by the convex junction of the coronary bone with the concave part of the coffin-bone, as explained in the article preceding.

**COLD.** See CATARRH.

**COLIC**, or **GRIPES**, are of two kinds: 1st, the spasmodic; 2nd, the inflammatory. The first proceeds from catching a slight cold in the bowels when these may be foul, or from drinking cold water; the second, or inflammatory, is brought on from the same two causes, more severely incurred, as well as from costiveness and consequent heat, terminating in inflammation of the bowels; as does tumour also.

The first kind of gripes is cured by one ounce of the *philonium romanum*, and by repeating it, if occasion be, with the help of oatmeal gruel in any quantity; or, the gruel with any other cordial than the *philonium*, which is thus compounded:—

Take Purified opium,	3 drachms
Ginger,	6 drachms
Jamaica pepper powdered,	1 ounce
Caraway seeds in powder,	6 drachms
Syrup of poppy, strong,	3 ounces;

mix in the opium with the warm syrup, minutely, and add the three powders. Divide into five or six doses. \*\*\* This is the *opiate confection* of the shops.

In the second kind of gripes, or natural inflammation, copious bleeding is proper; which should be repeated if necessary, that is, if the pain and pulse appear to be very violent. The excrement should be kept raked away as it falls into the rectum, or straight gut. Sweet oil should be given, 1½ pint, inwardly, to relax the intestines; and then cooling laxative salts, every four hours, to unload the same; for which purpose, also, any of the neutral salts may be employed, as Glauber's salts, *sal catharticum*, with soluble tartar, or tartarized kali; and oil given by way of clysters will also be of use in this case. Here, saltpetre is not so proper, because it acts as a diuretic, rather than a laxative.

Now, this last kind of colic, proceeding

as it does from costiveness, or from a severe cold in the bowels, causing inflammation of the bowels, is what the writers and farriers indiscriminately call "the strangullion," or "twisting of the guts," for such they always suppose it to be. Yet this never happens originally, though it may be effected by some other misfortune. The plain truth is, that certain particles or pieces of dung, or excrement, in passing through the guts, become hard or indurated from an excessive degree of dryness, or heat in the system; whence it comes to pass, that the space of the gut where it rests is stretched and enlarged. Hence follows a narrowness or stricture round the adjacent part of the same, so that the excrement cannot pass along. This occasions an inflammation; and the horse, if not soon relieved by cooling and relaxing medicines, dies of a mortification in such part. Another cause may be inflammation of some particular part of the intestines, where the excrement may not be so lodged; that is to say, a tumour or tubercle on the mesentery.

Thus you see how necessary it is carefully to discriminate betwixt those different kinds of colic, which will be best done by observing whether there be fever attending it or not; to ascertain the existence of which, or not, the pulsation of the artery is to be consulted, which may be felt on the hinder part of the fore leg, either above or below the knee of the horse; increased action thereof being indicative of inflammation, which is ever accompanied by cold ears and cold legs. Moreover, the horse in this last case will be frequently looking back to his flank, by which he points out in some measure the seat and nature of his disease, though not with absolute certainty; for the same symptoms will attend the horse afflicted with the stone or gravel, which, by the bye, I believe, happens but seldom; but much greater certainty may be gathered even with respect to the difference of these complaints, by paying due attention to the nature and dryness of his dung or excrements, or his frequent attempts and motions to void his urine. But, whichever of these is the disease, thus far you will be right, that the proposed remedies will be proper in both complaints alike.

**COLOUR OF HORSES.** It is a disputed point amongst veterinarians, even of the present day, whether the colour of a horse, or of any other domestic quadruped, is any indication of excellence or of defect. The celebrated Gibson, whose

experience and knowledge of the horse cannot well be disputed, observes, that not only much of the beauty of a horse depends upon his being well marked, and of a good colour, but also that his good or bad properties are sometimes denoted by his being of this or that colour, or his having such and such marks. Though, indeed, (he further adds,) these appearances are not always to be depended on, for daily experience teaches us, that, however true these observations may prove in the main, yet we often meet with good horses that are very ill marked, and of bad colours; and sometimes very bad horses that have almost all the beauty that colour and marks can give them. He concludes, however, that it is necessary for those who have any concern among horses to be more or less acquainted with such things: for this reason we shall here cite his opinions.

The chief and principal colours are the bay, the chesnut, the black, the brown, the dappled grey, and sorrel. For the white is for the most part originally grey, which turns sooner or later into white, as his limbs happen to be lighter or darker; for the light grey colts, that grow the soonest white, have generally little or no dark mixture about their joints.

1. The *bays*, perhaps so called from their resembling the colour of dried bay leaves, are of various degrees, from the lightest bay to the dark, that approaches the nearest to the brown, but always more shining and gay. The bright bay is an exceedingly beautiful colour; because a bright bay horse has often a reddish dash, with a gilded aspect, his mane and tail black, with a black or dark list down his back. Also the middle colours of bay have often the black list, with black mane and tail. And the dark bays have almost always their knees and pasterns black; and we meet with several sorts of bays that have their whole limbs black from their knees and hocks downwards. The bays that have no list down their backs are for the most part black over their reins, which goes off by an imperceptible gradation from dark to light towards the belly and flanks. Some of these incline to a brown, and are more or less dappled. The bay is one of the best colours, and horses of all the different kinds of bays are commonly good, except when accidents happen to spoil them while they are colts.

2. The true *chesnut* is generally of one colour, without any shade or gradation: his hairs are often compounded of three

colours, the root light, the middle dark, and the points of a pale brown, which make an agreeable mixture, and differ from the sorrel in this, that the mixture of the chesnut is not so distinct and apparent to the eye, especially at any distance, because the hairs of the sorrel are often of several colours intermixed, wherein the red or fox colour generally predominates. Many chesnut horses have their manes and tails very near the colour of their bodies; many of them have but little white about their legs, and frequently no mark, whereas the sorrel have generally a good deal of white about their legs and pasterns; many of the sorrels have a large blaze, and not a few are bald all over the face, while their manes and tails are sandy or of a flaxen colour. Both the chesnut and sorrel are of degrees darker and lighter, and there are some chesnut horses with manes and tails as light as the sorrel, and the hair all over their bodies approaching towards a fallow colour, only with a sort of beautiful chesnut stain.

There are many very good horses, both of the chesnut and sorrel; but the latter, when they have much white about their limbs, are apt to be more faulty in their feet than those that are more uniform in colour, and they are also apt to be more tender in constitution. When a chesnut horse happens to be bald or party-coloured, or to have white legs, which may be owing to some extraordinary affection in the dam, or some improper mixture in the breed, such horses are not very agreeable, for chesnuts are the least tainted in their colour of any other, and most people prefer the chesnut to the sorrel, both in point of beauty and goodness.

3. The *brown* is a colour not altogether so beautiful as the bay or chesnut. Browns have also their degrees, some being light, and some very dark. They have almost all black manes and tails, and often their joints are black, though not so shining as the bays, but rusty. Almost all brown horses grow gradually lighter towards their bellies and flanks, and many are light about their muzzles. The most beautiful are those that happen to be finely dappled, for the plain brown are esteemed more ordinary. Many of them are coarse, but strong and serviceable, fit for draught, for burden, or for the wars.

4. *Black* horses are very beautiful, especially when they are of a jet shining black and well marked, and have not too much white. For, as a great deal of

white, especially when it spreads round the eyes, and a great way up their legs, adds nothing to their beauty, so neither does it add any thing to their goodness. The English black horses have more white than the black horses of any other country. Gibson says, he knew many fine Spanish horses, some Arabs, and one Egyptian (the only one he ever saw of that country), all without any white. The Dutch and Danish horses seldom have much; though he thinks a star or blaze, and sometimes a white muzzle, and one or more of the feet tipped with white, beautiful, and no diminution to the goodness of a horse. On the contrary, some think these an addition, from an opinion that horses without mark are generally stubborn and ill conditioned. Some black horses have brown muzzles, are brownish on their flanks and between their hips. These are often called black browns, as they are not a perfect black, but approach near to the colour of a tawny black hound; some are of a lighter colour about their muzzles, and are called mealy-mouthed horses; and of this sort are the pigeon-eyed horses, which have a white circle round their eye-lids, and their fundamentals often white. But, after all, he says he found many of the English black horses, especially of the largest breed, not so hardy as the bays and chesnuts, &c. Those that partake most of the brown are generally the strongest in constitution.

5. The *greys* are so diversified in colour, and so common and well known, that it would be a needless labour to describe them particularly. The dappled greys are reckoned the best, and are to be found in most parts of the world. The silver grey is extremely beautiful, and many of them very good. The iron grey, with light mane and tail, have also a gay appearance, but are not accounted the most hardy. The light plain grey and the pigeon-coloured grey soon change and turn white, as all other greys do in process of time. The dappled grey keeps his first colour the longest, which is a sign of strength and durableness. Some of them have become pretty old before they have changed, and never so perfectly as not to retain some vestiges of their native colour. The nutmeg grey, where the dapples and other mixture participate of the bay or chesnut, is not only exceedingly beautiful, but most of the nutmeg-coloured horses turn out very hardy and good.

6. The *roans* are a mixture of various

colours, wherein the white predominates. Many of them turn out much better than they appear to be. Some are exceedingly good, and those that have a mixture of the bay or nutmeg colour are sometimes tolerably handsome and beautiful. The roans have a general resemblance to each other, and yet a very great diversity: some are strewed over with white as if they were powdered or dusted with flour, and some as if milk had been spilt all over their buttocks; others as if they were powdered with soot or lamp-black, and some as if their faces had been dipped in a bag of soot. Many of these are good road horses and hardy.

7. The *strawberry* approaches pretty near the roan in some things, but in most resembles the sorrel, being often marked with white on his face and legs, which we seldom observe perfect without mixture on the roan. The bay mixture in the strawberry is also of the highest colour, and makes him look as if he was tintured with claret; some of this sort are both handsome and good, but not very common.

8. The *fallow colour*, the *dun*, and the *cream colour*, have all one common resemblance, and most of them have a list down their backs, with their manes and tails black. The mouse-dun and the lead colour are the most ordinary; and, because the list down their backs goes off with a soft imperceptible shade, like what we observe on the back of an eel, are from thence called eel-backed. Few people choose dun horses, though horses of this colour often prove useful in the hands of country people. The fallow and cream-coloured horses are many of them both good and beautiful. Those are generally the best, that, besides their manes and tails, have their muzzles and their joints black or chesnut, and their colour a little inclined to chesnut. Gibson asserts, that he has known some with manes and tails of a *silver* colour, not only extremely beautiful, but very good and useful. The fallow and tawny duns are often shaded with a darker colour, and sometimes faintly dappled, and look very fine in a set, when they happen to be well matched.

There are many other colours of horses produced out of the great diversity that are to be met with every where, which would be endless and of no great use to describe, as the *peach colour*, *starling*, and *flea-bitten*, &c. and all these participate more or less of some of the colours already mentioned. Sometimes horses turn out

very finely spotted, some like leopards or tigers, some like deer, with black, red, yellow, or other gay colours; and when these happen also to be comely in shape and appearance, they are generally reserved as presents for princes, or other great men, though perhaps more for their singularity than any superior excellence in them. Others again are so disagreeably diversified in their colours, and in such a remarkable manner, that they are usually condemned to the meanest drudgery.

Though we have stated the opinions of Gibson on this subject at some length, we shall here add those of a more modern writer, as being somewhat in opposition to the former.

In his treatise on horses, Mr. John Lawrence adopts an adage of the noted Bracken, who says, that "a good horse is never of a bad colour." "Modern light and experience, says Mr. Lawrence, have been happily employed in detecting and exploding the theoretic whimsies of antiquity upon almost all subjects; among the rest, upon that of attributing this or that good or evil quality or temperament to the colour of a horse. All that I am warranted in saying, from my own observation, is, that I have seen more bad horses of all kinds among the light bays, with light-coloured legs and muzzle, than amongst any other colours; and the most good saddle and coach horses among the common bays, with black legs and manes, and the chocolate browns. This, in all probability, has been accidental."

COLT, in the general sense, and immediate acceptation of the term, implies a produce from horse and mare, without adverting for the moment to either the masculine or the feminine gender; but in a more contracted point of view, (as well as in just and sporting-like phraseology,) it is meant to convey an unequivocal idea, that the produce being a colt, is really so, (that is, a horse colt,) in contradistinction to the opposite gender, invariably called a filly. The bone and growth of a colt depend greatly upon two circumstances: the first, his being foaled late or early; that is, early in April or late in June; as well as the difference of his being weaned in November or March. Although it is admitted that colts (in the first year termed foals) running with the dam during the winter, will afford greater probability of size, bone, and strength, yet it is not at all times it can be complied with, unless in studs, where brood mares are

kept for that purpose only, and are left fallow (uncovered) for the season. When a mare has been covered with a foal at her foot, and is evidently in foal again, it should be an invariable rule to wean the foal in October or November, upon the palpable impossibility of giving suck to the one without an impoverishment of the other. Whether the colt is, or is not, weaned in either of those months, he should be well kept, and have daily supplies of corn and hay, as well as proper stable, shed, or shelter from the inclemency of the winter season. Upon the liberal keep of the two first winters, his size, growth, strength, and bone, entirely depend, and must be particularly attended to, lest repentance come too late; for it must be held in remembrance, that if a colt is small at two years old, from having been stinted in keep, there is not one in a hundred ever attains to good size by any additional exertions or expense, after the natural efforts for expansion have been so long retarded.

#### CONCUSSION OF THE FOOT.

For lameness arising from a sudden false step, which Lafosse calls concussion, and which he accounts for by the action of the coronary bone, then pushing the nut bone against the tendon, and compressing the same as between an anvil and a hammer, he has proposed two remedies, to remove the inflammation that ensues, and its bad consequences. One is to draw the outer sole; the other is to pare it, till it becomes thin and flexible, to bleed in the foot, and to use emollient poultices and fomentations round the foot and the coronet. Three-fourths of these cases, he says, are cured by such methods without drawing the sole; and I beg leave to add, that I believe all might be, if they were taken in hand immediately, and the crust or hoof were also pared down as low as possible, and rendered thin on every part; because the interior inflamed parts will be more relieved by external applications, when the thickness and stricture of the crust are removed, than when the outer sole only is pared away. But the great objection I have to drawing the sole, besides the cruelty of the operation, is, that nineteen horses in twenty (here in England I mean) have always been more or less lame afterwards, when used again, and that from contraction of the hoof occasioned by such operation. In either case a run at grass effects wonders.

**CONDITION AND STABLE MANAGEMENT.** The grand and principal

aim of a groom should be to put and keep his horses in what is termed condition—let us, therefore, consider what is condition. The word condition is variously applied to the horse, though widely different from what is here implied; for instance, we say a horse is in condition for sale—that implies he is in flesh, his legs clean and fresh, his coat decently fine, and perfectly sound; a horse may be all this, but not in condition for work. Another horse is said to be in good working condition; such might be said of a post-horse, that is of bare flesh, his joints enlarged, and puffed with wind-galls; yet this horse is capable of doing much work, and his being worked more than was requisite to keep him in condition, has put him out of condition. Condition, therefore, without an expletive, implies that perfect state of body and limbs, in which the whole system is the most vigorous, and capable of great exertion, if required; and this cannot be obtained or kept, without strictly adhering to three things, viz. proper food—proper grooming—and proper exercise; neither of these must be omitted, or injudiciously administered, for, like unto medicine properly administered, it does good, but is capable of doing much injury, if profusely taken or misapplied. Wine, in moderation, cheers the spirits and invigorates the body, but taken to excess, debilitates and weakens the constitution. The food of the horse, consisting only of hay and oats, and his drink only water, may be thought of such simple and inoffensive qualities, that only holding them from the horse would do him injury; but quality and quantity, proportioned to his habit of body or constitution, must be particularly attended to. If the quality be bad, it will make him foul, and will not afford the nutriment that clean wholesome food yields; if you feed too plentifully for the work or exercise the horse has, you will make him too fleshy and gross, and probably make him fly to pieces, as they term it; that is, he will become languid and dull from the blood being too thick—his stomach overcharged, and want of digestion, a fever ensues, or he breaks out in humours, mostly about the legs, or places most remote from the heart, where the thickness and foulness of the blood prevents a free circulation; again, if you disproportion your feed by giving him too much hay, this will cause him to drink freely, and run to belly; blowing him out with this description of food which affords the least

nutriment, a horse cannot endure much labour, and his wind will be distressed. Hay is the natural food for the horse, but not the most heartening to work upon; therefore, a horse to be kept in condition, must be fed sparingly of hay, but that of the very best quality. To ascertain the quantity of hay a horse should have, depends much on his size, his constitution, the nature of his work, &c.; hence, if a horse is put to fast work, his food should be of that quality that affords the most nutriment, lies in the smallest compass, and requires the least water to digest it, whereby the horse's wind will be the least distressed. If his work is hard, that is, continued for several hours, but not at any extraordinary speed, he may have more abundantly of hay, and even beans with his oats. Chaff, if sweet and good, is proper for some horses, such as have thin light carcasses, and do not work hard; to those which eat their corn greedily, without masticating it, and it comes away whole in their dung, a handful or two of good sweet chaff will be infinitely serviceable, as they will be obliged to chew and masticate the oats with the chaff, before they can swallow it. But though chaff is filling and cooling, it must be sparingly given to horses required to be in condition; it fills a horse and makes him drink, by which he will appear plump and fair to the eye, but not in condition to work. It is most proper for slow draught horses.

To convey some idea of the quantity of hay that may be necessary for a nag horse, I shall say from eight to twelve pounds per day, according to size, constitution, &c. so that if we take the medium, about ten pounds will be found generally sufficient; but large carriage horses will require more, we may say from thirteen to twenty pounds per day. Having mentioned an indefinite quantity, judgment, according to circumstances, must direct the rest. If your horses get lank and more hollow in the flank and quarters than you like, you must increase their usual allowance; but, on the contrary, you must not, for the sake of having your horses fat and plump, supply them with too much hay and water; a horse, when fat, is less fit for work than when lean and poor, provided that poverty was not occasioned by starvation, for a horse may be lean and poor by his work exceeding his keep; or if a horse is stinted to an allowance that would keep him in a tolerable plight with only a little walking exercise, and then is put to work without an

increase of food, he will of course become thin; but if you have not taken so much out of him as to exhaust his strength as well as his flesh, he will become nothing the worse for it; increase his feed, and he will be better for work than before.

A horse that is full of flesh, though it may be in consequence of good and wholesome food, with good looking after and regular exercise, is, nevertheless, not in that condition that is most desirable; for his flesh in this state is an incumbrance, were you to put him to an excessive day's labour before you had gradually reduced his flesh, it might throw him into a surfeit, or the like.

Good oats are the most hearty and best food for saddle horses, if given in proper quantities; this must, in some measure, be proportioned to the work or exercise the horse has; you may keep a horse in condition with three quarterns of oats per day, provided his work is no more than exercise; but if you work much, you must increase his feed proportionably and according to his constitution, some horses being much heartier feeders than others. If the horse is kept to constant hard work, you are in no danger of over-feeding him, if you were to give him as much as he could eat; but high feed, without work, would, as I have observed, make him gross and unfit for work.

Beans are good and heartening food for working horses, but not proper for horses whose work is light, nor for horses who are required to go at speed; they require more water to digest them, and swell, consequently cannot but distress the wind of horses required to go fast, and would be too gross for horses that have not plenty of work; they may be allowed to horses who travel much at a moderate rate, draught horses and the like.

Water is usually given twice a day. Soft water is esteemed preferable to hard spring water; hence, rivers and running streams are better than water pumped from a fine spring; where such are not handy, springs that supply ponds, where the water gets impregnated and softened by a loamy or chalky soil, will be better than hard spring water. The quantity in this must be directed by circumstances, size of the horse, constitution, &c. some horses will not drink immoderately, and may be left to their own discretion, while others, if you let them, would swill, and render themselves incapable of work, causing immoderate perspiration, and dis-

tress of wind ; such must be restrained to a moderate quantity, that they may be fit for work if they are instantly wanted ; when the work is done for the day, water may be allowed in reason ; but some horses will always require to be allowed, or they would drink greedily, and enlarge their bellies like unto cows ; it is not a bad sign, nor should a horse be rejected on account of a large belly ; it is a sign of good constitution and a good feeder, and nothing is more easy, with proper feeding and exercise, to bring it to proper shape. Half a stable-pail of water is generally sufficient for the morning ; in the evening the horse may drink more plentifully, if his belly does not get over large, which is to be much attended to, for by that you are to regulate his allowance of hay and water.

The first thing to be done at going to stable, after casting your eye round to see if any horses are loose, cast, and the like, is to rack and feed. The judgment in racking, is to give the horse but little at a time, that he may eat it with an appetite, clearing his rack, and picking up his crumbs. If a horse leaves hay that is good and sweet, some cause must be assigned for it, and it should be examined into—sometimes the cats will foul the hay, and horses are very nice in their food when not kept scanty. If the horse appears to be in health, and the hay has not been blown on by other horses, but is fresh and sweet, I should judge he is too plentifully fed, leaving hay for the sake of oats ; this should be guarded against ; therefore, if you give hay that is good and clean in moderation, I would recommend to shorten his allowance of oats, to bring his stomach to the small quantity of hay that I recommend to be given. His morning's racking should be one quarter of his daily allowance, which, on the average, is about three pounds for his breakfast ; for abundant feeding in the morning is not good ; a horse cannot work pleasant to himself when over full, and therefore feed sparingly in the morning, lest you may want some exertion from him, and not suppose that a full belly will make him perform better ; it is food which he has digested, the nutriment of which is then in his veins, that is to support him, and not what you cram into him at the time you want great exertion from him ; a good horse, in proper condition, will not flag in twelve hours, if you require that much of him ; and I have many times rode a horse for twelve hours, and on a

moderate computation suppose he has carried me a hundred miles, without (as it is termed) drawing bit ; but this is not to be expected from every horse—none but thorough good horses, in proper condition, can undergo such extraordinary exertions.

The quantity of hay that is given, should be shaken to clear it from dust and seeds, and if it is very dry, as it will be, sprinkling it with water will make it more agreeable to the horse, and he will eat with better appetite. I have known several horses, when they perceive or think they are going out with the hounds, refuse to eat their hay and oats ; this arises from an impatient and pleasing anxiety of mind—the pleasing prospect of the chase, of which most horses are fond, but some uncommonly so ; but whether they disregard their food from this pleasing anxiety, as children will when the prospect of pleasure is arrived, or whether they refuse their food knowing they will be better able to gallop with an empty stomach, I won't pretend to determine ; but certain it is, the horses that have come within my knowledge, never performed the worse for it ; and I likewise noticed, they were not off their feed when the day was over : therefore, a horse refusing his food under such circumstances, I do not deem a bad prognostic. But it is very common for a horse to be off his feed after any great exertion, and this is by no means a desirable circumstance.

After having racked with hay, you next feed, as it is termed, that is, serving the oats. I proceed in the routine that is to be daily observed, for were I to treat of things out of this regular order, young hands might be studying what they should do, and what ought to be done first ; and it is no uncommon thing to see some that have been in the stable employment for a length of time, not know which thing to do first, and occasion themselves trouble and loss of time by going wrong about things. Now in serving the oats, whatever is deemed a sufficient allowance for the horse for a day, whether it be three quarters or a peck, one fourth of the quantity should now be given ; as sweet and clean food is most agreeable to the horse, as well as most beneficial ; carefully sift the corn from the dust, blow away the chaff, and pick out any thing you perceive is unfit or unpleasant, which will sometimes be found among them, frequently rat's dung

and cat's dung; then clean the manger with a small wisp of hay or straw, and throwing in the oats, spread them with your hand, to prevent the horse from taking too greedy a mouthful at a time, whereby he would be induced to swallow them without chewing.

While the horses are eating their corn, you begin to put the stable fair, or, on those days which you give clean litter, to muck out: you take the stable-fork, and begin with great care, for much injury has been done by heedlessly using the fork, first to throw all the dung off the litter clear out behind, then turning up the dryest and best of the litter under the manger, and the wet and mucky you turn out behind the horse with the dung, leaving a part, consisting of dry short litter, if it is not on the days of your entire mucking out, which are generally Wednesdays and Saturdays; at which times you turn up the best of the dry short litter, as a reserve for the bottom of the new bed, to be placed where the horse is most liable to wet and spoil litter; and then sweep all the dust, dung, and every thing that is offensive, away, and clear it out of the stable as expeditiously as you can; for the air in the stable is always impregnated with the effluvium from the dung, but more particularly at the times of cleaning and mucking out, which must be more injurious than beneficial to the horse.

The stable being cleared of muck and dung, next begin to clean your horses: this is a work that requires more knowledge and judgment than at first appears. The currycomb is the first thing applied, and great attention should be paid to its being applicable to the horse; some horses require much of the curry-comb, others none—this depends on the state the horse is in, time of year, &c. Horses whose coats are long and full of dust, such as are just taken up from grass, or those just come out of persons' hands that either do not know how, or do not take the pains, to keep a horse's coat clean and fine, will require the free use of the curry-comb, and the teeth and sharpness of the comb should be proportioned to the thickness, length, and foulness of the coat; while horses that have been kept in stable, and properly groomed, have their coats fine, thin, soft, and clean, requiring no other use of the curry-comb than merely to clean the brush, or occasionally to rub off any dung the horse may have lain on; the teeth of such comb should be re-

markably even and dull, not to scratch him.

These things being attended to, after stripping the cloaths off, you should then use the curry-comb, always beginning on the near side at the hind quarters, and using it in proportion to the length and foulness of the coat, that is, if the coat is fast on, long, full of dust and very filthy, you should use it very freely to loosen the coat, or the sweat that is dried and fast on the skin and roots of the hair, appearing like a white and saltish dust; but though I say you may use it freely for this purpose, you are not to expect you are to get it all out at once; it will be a work of time; and to attempt it by using the curry-comb too much, you would set the coat on end, open the pores of the skin, and give the horse cold, which would obstruct that imperceptible perspiration which is always discharging itself through the pores of the skin in horses like unto us, and then an ichor will issue from the obstructed pores, which will dry into small scabs, and the coat will stare; therefore, when I say use the comb freely, I mean comparatively to what you do with horses whose coats are fine and clean; over diligent grooms, who do not thoroughly understand their business, but take abundant pains to excel, if possible, are apt to run into this and the like extremes. Another thing to be observed is, that if it is the season the horse is changing his coat, (at which time it will come off very fast with the curry-comb) I would not advise you to use the comb more abundantly for the purpose of pulling off the coat, but let it have its time to come off; for to hasten the old coat off would subject the horse to cold, and that might occasion his new coat to grow long, which is not desirable; Providence has wisely so ordered things, that the horse's coat, if exposed to cold, shall grow long, and if you keep him warm, his coat will be the shorter.

Proceeding, then, to curry on the hind quarter, for the purpose of unmatting the hair, and loosening the dust, you descend down the quarters, particularly attending to rub off all dried dung, and minding not to injure or scratch the horse; the legs, below the houghs, are not to be touched with the curry-comb, unless there is any dung on the point of the hough, which you may carefully endeavour to loosen with the curry-comb; but the comb does not work pleasant on that part, and you must handle it very light, and with the greater

care. You next proceed to the fillets, back, loins, flank, belly, shoulders, arms, bosom, and neck, omitting no part that the curry-comb can be conveniently applied to; but tender places, or those thin of hair, need not be touched: observe, therefore, with the curry-comb, to begin at the hind quarters and finish at the head, which seldom need be touched with the curry-comb. Horses are not ticklish when their coats are full of the dust occasioned by the natural and imperceptible perspiration of the body, but as they get clean, and their coats short and fine, they are exceedingly ticklish, and you must be careful to stand in a secure place. After currying the near side, you next proceed with the off side; and here it becomes necessary to use your left hand, which, after a while, you will find most handy and convenient; this done, you next proceed to wisp off the dust you have raised by the curry-comb, and to rub and wisp those places which were not proper for the curry-comb to touch. For this purpose, you make a wisp of some half-worn straw, but a hay-band is better, which prepare for the purpose by half untwisting it; loosening it thus, you double it to about twelve inches in length, loosely twisting it together that it may not scatter away too fast, till you have it as thick as you can grasp; if it is dry and harsh, sprinkle it with water; this will make it work more pleasant, and the dust you intend to remove will thereby adhere to it, and not fly so much about. This wisp with care, if properly made, will serve you several times, and consequently, when one is worn out, you must make another.

You begin to wisp the horse at his head; taking the wisp in your right hand, you place your left hand on his nose, to hold the head steady, and wisp first his forehead over the eye, behind, and round the root of his ear, down his cheek, and particularly under his thropple, rubbing pretty hard, particularly if there is dried sweat and dust, which will be the case after having been out in hot weather and dusty roads.

The head being thus finished, you change the wisp into your left hand, and resting the right hand on the most convenient part of the horse to steady yourself while you apply the wisp, you change its situation according to the part you are rubbing, and begin at the top of the neck, and proceed downward to the shoulders, the under part of the neck, the bosom

particularly, between the fore-legs, down the arms, knees, sinews, and fetlocks; no part is to be left unwisped, but you must apply the wisp harder and most where it was not proper to use the curry-comb; you then proceed to the withers, and apply the wisp to every part of the body, but particularly under the elbow or arm, and again between the fore-legs and chest, for which purpose you take the wisp in the right hand, which done, you change again the wisp to the left, and rub under the brisket and belly, and from thence under the flank, the sheath, under and between the thighs as far as you can reach. This part is the most difficult with ticklish horses, but must not, on any account, be omitted; for this purpose, place your right hand on the horse's hip, put your left shoulder against him, and your head in his flank; in this position you rub as far as you can reach with the left hand, and support the horse, who will lean against you, and some will nearly lean their whole weight on you, they are so exceedingly ticklish, which, when you are used to, and find yourself secure from injury, you will disregard.

You next proceed to wisp the hind quarter, not omitting to wisp under the dock, and between the quarters; for this purpose, again take the wisp in the right hand, and take hold of the dock with your left, and place yourself as distant on the side of his quarter, as will not prevent your reaching to rub between his buttocks as far as the left hand rubbed under, so that none of these soft and ticklish places are left untouched; this done, you proceed down the thigh, hough, sinews, and fetlock, both inside and out, rubbing most where the curry-comb could not be applied, and particularly the joints and fetlocks; this finishes the near side, and then you proceed, in the like manner, with the off side, reversing the hand for that purpose; for in dressing or rubbing of horses a person must be as ready with one hand as the other.

When you have finished wisping the off side, carefully observing to leave no part untouched, and not sparing your labour on those parts not proper for the curry-comb to touch, (particularly if any dried sweat or dirt should, through negligence, have been left at his original cleaning, after having been out) proceed next to brush him over. You should commence with clearing your brush of dust, by rubbing it on the curry-comb, and begin in like manner with the brush

as you did with the wisp, first at the head, then taking the brush in the left hand and curry-comb in the right, proceed down the neck, brushing more particularly those parts where the dust is most likely to lodge, or most difficult to get out, such as the scurf of the neck next the head, down the scrag next the mane; these places are scurfy, and most difficult to get free from dust; therefore the brush on such places must be much applied backward and forward, always finishing the two or three last strokes the same way as the hair, to lay the coat smooth; every two or three strokes, you should clear the brush from dust, by rubbing it on the curry-comb; proceed in the same order from place to place as you did with the wisp, changing the hand to accomplish those places you find most convenient, as with the wisp, and particularly attending to brush where the curry-comb could not be applied; therefore, under the chest, between the fore-legs, the inside of the elbow or arm, and all nooks and corners, within the fetlocks, &c. must not be omitted; the loins, and where the hair feathers or divides different ways, as under the hip-bone, are difficult to get clean; much brushing and finishing strokes are necessary, to lay the coat smooth the respective way the hair grows; under the sheath, and places where no hair grows, you need not brush, the wisp and rubbing-cloth being sufficient for them. Having thus gone over first the near side, and then the off, with equal care and attention, especially those parts I have particularly mentioned, for I have noticed (being much among them) that many stable-men attend most to those places that are conspicuous to the eye, such as the full of the neck, the shoulders, and hind quarters—these places are least difficult, and always shine the most, and they do not fail to point out these to you, and say how well they look, which may satisfy some persons; but a judge will not be deceived by external appearances; he expects the parts not immediately in view to be equally attended to, and examines between the fore-arms, within the elbow, where there must be no gumminess or clammy foulness, but clean, smooth, and soft as satin. Under the flank, the sheath, between the hind quarters, must be free from dust, soft, and clean as not to soil a cambric handkerchief. But to proceed.

After the brushing (which causes much of the dust to be floating about, and a part of it will settle again on the horse), you should have a duster to wipe him

over before you put his cloaths on; some have a coarse flaxen cloth for this purpose, others a hair-cloth, and some a piece of flannel, or part of an old horse-rug—either may do, but cloths which may be the easiest washed, and kept for that purpose, are best; with this you wipe him all over, beginning as with the wisp or brush, at the head, and so proceeding to every part, which, being done, you put on his cloaths, before you finish with his head, mane, tail, and legs, that the horse may not chill or take cold while you are about them.

There are some pains to be taken in buckling a cloth on, for if not even and exact it appears unpleasant to the eye, and may be very uncomfortable to the horse; therefore, great exactness is to be observed in placing it; throwing it over too forward, take notice if it is equal on both sides and square; then go behind his hind quarters, and, with a hand on each side, draw it down to its proper situation, which lays the coat smooth with it; if you have a fillet cloth as well as cloth or sheet, you will of course place that first, and the sheet over that, but so much cloathing is not used as formerly, for it only subjects the horse the more to take cold; further, I am only treating at present on the method to be pursued in the hackney stable, and not in the racing and hunting-stable; therefore a single cloth or sheet, and in winter a breast-plate, is as much as is necessary.—Having placed it as directed, lay the pad of the roller on the middle and hollow of the back, and should it be what is termed a sheet, which is a cloth made to wrap over under the brisket, be mindful to wrap it smooth and tight, that when the roller comes to be buckled, it may not be in wrinkles, nor gape or hang in a bag, or open under the belly; to prevent which, as you pull the sheet tight under the belly, wrap it forward, that it may lie quite close to the belly; for if this is not attended to, it will not only be awkward to the eye, but unpleasant to the horse, admitting of cold wind instead of protecting against it, and the horse when he stales, will wet and make it filthy; wrapping it with care to prevent these inconveniences, bring your roller under, and buckle it moderately tight, that the cloth and roller may keep their places, but not so tight as to render the horse uncomfortable, and minding to pull and adjust every part, to lie close and free from wrinkles; should the cloth hang wide at the flank,

or the sheet gape, as I have cautioned against, under the belly, lay hold of the bottom of the cloth or sheet, just before the roller under the belly, and pull it forward, which will make it sit close to the flank and belly.

The cloth being properly on, loosen the horse's head, take off his stall-collar, and turn him about in the stall, to give his head and ears a complete rubbing and brushing, which was not so practicable with the stall-collar on; you now brush his head over in every part, particularly at the root of the ears, and under the thropple, and after with your dusting-cloth rub and wipe him well, then pull his ears through your hands, observing they are clean and soft, and moderately cool; you then take your mane-comb, and comb out his fore-top and mane; then with a water-brush or sponge wet the top or roots of the mane, and pass a small rug or cloth for that purpose over it, putting one end of the cloth over on the near side at the top, pull it over to the off side, pressing the mane, and hair next the root of the mane, down, to make it lie smooth, which, this being your continual practice, will not fail to do.

You must then buckle on his stall-collar, and comb his tail; lifting up his dock, wipe away any dirt or filth that may be lodged there, either with your hand, a cloth, or wet sponge, as may be most convenient. His feet are next to be examined, and the dung or litter picked out, and, if necessary (any dung which is of a glutinous quality sticking to them) must be washed. And, lastly, the legs are to be rubbed with a clean loose wisp of straw in each hand, for which purpose you should go down on both knees, pass the wisp down the legs and sinews, and finish with passing your hands down in like manner, to feel that they are smooth, and no particles of the straw (or thistles, which might be among it) adhere to or stick in the hair; these rubbings are to put the blood in circulation in these parts which are remote from the heart; for with some constitutions it is difficult to prevent a degree of stagnation, which causes the legs to get round, and, if neglected, would become what is termed the grease.

The dressing thus finished, give him his water, the quantity agreeable to circumstances, that is, if the horse is inclined to have too much belly, you are to shorten his allowance of water and hay; if he is immediately going out,

don't let him drink too plentifully, for no horse can travel or work well, if blown out with hay and water; on a long journey a horse may be permitted to refresh his mouth with washing, and taking a few swallows frequently, but not to satisfy himself with water till his day's work is done. I am speaking here of the hackney, which will not be required to travel faster than eight or nine miles an hour; but if you intend to travel faster, his work should be the sooner done, and washing his mouth is all the water he should have till he has got to his journey's end.

Having given him his water, give him another feed of corn, sifting his corn and cleaning his manger out as before observed; then shake up his litter, and again set the stable fair. The horse is now in readiness whenever he may be wanted.

Cleaning the furniture is the next consideration. Saddles and bridles must be cleaned with a sponge from all road dirt; the stirrups, bits and buckles, should be cleaned with such materials as will not injure the polish; fine sand burnt in a shovel, Flanders' brick, rotten stone, or charcoal dust, are fit for the purpose; any of these used with a piece of leather, dry, will preserve the polish without scratching them, which should be carefully guarded against, for it would be needless to have high-polished bits and stirrups, if coarse materials were used to scratch and spoil the beauty of them. When they are used, the instant they are taken off they should be wiped from the dirt, and the oil-brush rubbed over them, to preserve them till you have an opportunity to clean them properly. Plated buckles may be rubbed with leather and whiting, but be careful not to smear and whiten the leather. I am thus particular, because without these precautions a person may give himself much unnecessary trouble.

Girths, when much dirtied by road dirt, and saddle-cloths with sweat, &c. must be washed clean with soap and water; if they are white, to keep them to a good colour, it is customary to use pipe-clay; nothing looks neater than white, and, by washing as above, they look decent to the last; but if you use pipe-clay, when dry, be mindful to brush all the dust out with a clean brush for that purpose, that they may not whiten any thing that touches them, or create a dust, which otherwise they would do; when all is cleaned, buckle the girths properly round the saddle, to keep the flaps down, and put

them in their proper appointed places, free from dust, &c.

The morning's business of the stable (excepting exercise) is thus completed; the remainder may be left till noon.

Before I proceed further, I shall here show the reasons for this manner of feeding the hackney, for I would not have it understood that this is the manner to feed for extraordinary cases, hunters, &c. A hackney should be always ready to perform ordinary work, with ease to himself and comfort to his rider: riding him for an airing five or six miles, I account moderate exercise, but to go thirty or forty miles an end, without drawing bit, at the rate from eight to ten miles an hour, (which I think any good hackney in condition ought to perform with ease) is what may be termed ordinary work—to gallop twenty miles, or trot sixteen in one hour, I call extraordinary work, and a regular mode of training should, therefore, be adopted. But for the hackney, it is to be observed, I have recommended him to be fed in the morning sparingly of hay, being only one fourth of his daily allowance, because it takes up much room, and requires more water to digest it, and I allow half his daily allowance of oats, because they take up the least room, and are the most heartening food. Should, therefore, the horse be wanted on a sudden, he has a foundation to support him for a long journey, and of that quality as will not encumber and distress his wind, if you go no faster than a travelling pace, riding moderately at first, till the horse has emptied himself a little, and after at such pace as the horse is able to maintain with perfect ease to himself; which I account to be at two-thirds or three-fourths of his speed, that is, if a horse at his best speed can only trot twelve miles within the hour, eight or nine miles are as much as he can do comfortably to himself, for the continuance of three or four hours, and so on in proportion for faster or slower horses. I don't say but a horse may do more, but then it becomes labour to both horse and rider; there are horses that will maintain this pace for ten or twelve hours together, witness Crocket's mare, that trotted one hundred miles in twelve hours on Sunbury common, about thirty or forty years back, and, no doubt, there are many others would do the same—Tom Thumb, for instance.

But to return. At noon give him the like quantity of hay as in the morning, and his feed of corn; set the stable fair,

that is, put his litter to rights, and take away his dung. This is all that is necessary till watering-time, which is about four o'clock, at which period you strip the horse, and brush him over.

I have had lads that could hardly be persuaded of the necessity of this, alleging that they had cleaned them perfectly well in the morning, that the horse had not been out of the stable, and that the clothing prevented dust from settling on them; therefore, they could not conceive the necessity of it, and many others may be of the same opinion. To satisfy them, I was obliged to explain, that the dust they brush out of the coat, is not the dust of the stable, but arises out of the skin from the imperceptible perspiration which is continually issuing through the pores. Besides, stripping the cloaths off, and brushing him over, greatly refreshes the horse, and puts the blood in a more free circulation.

Currying and wipping may be here dispensed with, unless the horse is newly taken up from grass, or the like, and that his coat is uncommonly thick and foul; in which case a moderate use of the curry-comb may be applied, so that you do not occasion the coat to stare; but, in general, the brushing and wipping are sufficient, finishing in like manner as was directed in the morning, with rubbing the legs, which must never be omitted, combing the mane, tail, &c. and then watering; if there is not a probability of the horse going out, let him have a greater quantity of water than in the morning, and if he is not a greedy horse for water, he will not drink more than will do him good; but, if you perceive his belly gets too large, you must allowance him.—Setting the stable fair, you have done till the final doing up for the night.

At about eight o'clock, go to the stable and finish for the night. You must now give him his remaining allowance of hay, being double what you gave in the morning, and his remaining feed of corn; you give hay more abundantly at night, because it will be in so forward a state of digestion in the morning, as not to occupy so much room in the stomach, which, when working, would obstruct the lungs and distress the wind; the explaining, therefore, the meaning or intention of your feeding, will be a guide how you should vary it upon particular occasions, so as to have the horse in good heart and spirits, but empty when wanted for expeditious purposes.

The last thing is, making up the beds, and setting all fair. In making up the beds, you contrive so lay all the worst of the litter in the middle or bottom, where the horse is most likely to wet and spoil it, and pulling down the litter you put up in the morning, reserve the cleanest and driest part to top the bed with, making the bed up high on each side, and fullest towards the hind quarters, that it may be soft and pleasant to the horse whichever side he lies on, as they will sometimes lie on one, and then on the other; throwing out all dung, and sweeping clean out, see that all the stall-collars are secure, loose cloaths taken off, and every thing fair, which finishes the routine of the stable.

I shall next speak of exercise, dirty horses, and the like.

Exercise is so essentially necessary and beneficial to the horse, that all the feeding and grooming will avail but little, if work or exercise is omitted. It is admitted that great numbers of horses are killed and spoiled with over-work, and, it is a doubt with me, if as many are not spoiled in London for want of work; there are several persons in London who keep horses, but are so occupied with business that they cannot ride them out oftener than once in the week, and many that I know don't ride them once in a month—their horses stand at livery, and they order them to be exercised, but what exercise can be given there, and by whom are they to be exercised?—Men employed in livery stables have seldom less than eight, and I have known some to have sixteen livery-horses to look after; these men, if they rub the dung off, and occasionally give them a brush over, omit exercise, not finding time for it. Gentlemen do not like to see or know that boys are permitted to ride their horses, and without they keep grooms their horses will go short of exercise. Consider, then, the state of those horses that are shut up in a stable very confined and filthy; if they are sometimes moved about, which they call *exercise*, it is on a ride perhaps fifty or sixty yards long, made of litter and dung, with a reeking dunghill at some part of it, so that the horse literally breathes only air strongly impregnated with the evaporation of dung: I think it surprising they are so well as they are.—The disorders it brings on them are a short cough, called (not improperly) a stable-cough; weakness in the joints, so that they frequently make a drop, as it is termed; various humours, swelled legs,

grease, and farcy; at their best, when they look plump and well to the eye, they are faint and foggy, and unable to perform more than would be common exercise for horses in condition; it is well they are not over-fed, but just sufficient to keep them in flesh; for were they to have the feed a horse should have to be in condition, they would fly to pieces the sooner for want of exercise.

Since, therefore, exercise and air are so beneficial, let us consider in what manner exercise should be given: this is to be regulated according to circumstances.—Where horses work two or three days in the week, the resting days require no more than airing exercise, for every horse should have at least two days in the week such work or exercise as gives him a good sweating; this throws out through the pores of the skin, what might otherwise lodge and breed humours; it likewise raises the scurf, adhering to the skin, and makes the coat fine; days, therefore, that the horse is not wanted for work, he must be exercised for the air, which is bracing and strengthening to the limbs, refreshes the body, and creates appetite: the early part of the day is preferable for this.

As soon as the stable has been cleaned out in the morning, which is while the horse is eating his first feed, brush him over, and put on his exercising saddle and bridle; in cold weather, if you only intend walking him, you may keep the cloth or sheet on under the saddle; in warm weather I do not recommend it, for, though a horse's coat may be something the finer by being kept warm, yet he is certainly the more liable to take cold when he is necessarily deprived of it.—The most open and airy places should be taken for exercise, and this is the most favourable opportunity to improve a horse's walk; for when he has only walking exercise, you have to walk him for two hours, which will be sufficient, and by aiming to extend his walk, you may greatly improve it—thus you exercise the horse, and improve him at the same time.—At your return, thoroughly clean him, give him his feed, &c. If you had convenience or opportunity while you were out, you might give him his water. If a horse is hardy, and inclined to flesh, I would rather recommend the like exercise in the afternoon, where persons have time and convenience, than to shorten his feed for that purpose; it would be much better for the horse, but every one cannot allow the time to be so taken up, for it would

be nearly equal to training, and may not be thought necessary; it is more than the generality of horses require, and many inferior-bred horses, who look well to the eye, cannot for a continuance stand the ordinary exercise that a horse has in training; such is the amazing difference of horses.

Should his work be so moderate as not to occasion a sweat, I think it beneficial, about twice a week, to give exercise strong enough to sweat him; this may be done in the pace he is mostly rode in, that he may be practised and improved in it; if he is admired for his trot, it would be wrong to gallop him, which might unsettle him in his esteemed pace; therefore, trot him out for the space of two miles, to bring him to a comfortable sweat, and walk him back; thus you extend his limbs, supple his joints, and strengthen the ligaments and sinews; for we know not our strength, unless we are put to it—inactivity debilitates, and over-exertion may sprain and weaken; but moderate exertion is good both for man and beast.

A lady's horse, if admired for the short united gallop, may be much improved in sweating exercise, if the exercising groom has a hand equal to the task, for no pace sweats so soon as the united gallop; the horse that is properly broke for a lady, is united or worked up to a certain pitch by a masterly hand, for ladies (few of them, however) are not capable of keeping them up to it, so that after a time the horse becomes less and less united, unless the groom in his exercise, can gallop the horse in extreme union, whereby the horse will ever be continued fit and pleasant for a lady's riding. Thus, in exercise, the esteemed pace, either walk, trot, short or extended gallop, may be practised and probably improved—for practice is the only mode of improvement.

Sweating and dirtying of horses occasions considerable labour to clean, and indolent grooms, and those who have several horses to look after, avoid this part of their business as much as possible; some would persuade you there is no necessity for it; but reason and experience teach us otherwise.

When horses come in from work or exercise, if in sweat, or wet and dirty with sloppy roads and rain, they should not be left till they are made completely dry, clean, and comfortable; some horses in good condition will rub dry and clean in a short time, but others, with long or curly coats, and some from constitution

or ill condition, are a long while getting dry. I have known an industrious groom to work at a horse for four hours, and would not leave him till dry, while others will cover them with a cloth, and leave them to dry before they will clean them; much depends on the habit the horse has been used to, constitution, condition, &c. whether the horse will take injury from being left in his wet and dirt; but those horses that have been properly groomed, having all care taken of them to keep their coats fine, and on all occasions made dry and comfortable, would be liable to take cold, which might be the forerunner of other diseases, if neglected at these times.

I must caution you not to suffer a practice which nothing but indolence and ignorance could ever have introduced, and what has cost many a horse his life; this is when a horse comes in (we'll admit thoroughly) wet and dirty as can be, to ride him into a pond, or wash the dirt off with a water-brush; this bad grooms will do, if permitted, all under the belly, and half up the body, alleging, that the horse cannot be wetter than he is, and that it will wash the dirt off, and he will dry the sooner. To such feasible arguments I have been obliged to oppose mine: that the horse was wet as possible I admitted, but that wet came on little by little as the horse splashed himself, and the heat of his body, with exercise, had tempered that wet to the heat of the body, and the horse was not so liable to injury from that; but to apply a body of cold water, which they must do to wash the dirt off, while the blood was in heat or fermentation, would strike a cold to the heart, close the pores, and obstruct nature in discharging herself by perspiration. I have been served thus at inns on the road, before I was aware of what they intended, and to prevent the consequences, I immediately made them be rode again, to keep the blood in circulation, and the parts thus chilled had recovered their heat, so that the pores might keep open to perform their offices.

Since the method of cleaning a horse in this wet condition of sweat and dirt, did not occur in the daily routine of the stable, I shall here introduce it.

The first thing after stripping the saddle, &c. off, when the horse is so wet with sweat or dirt as to require it, is the scraper, usually made of a flat piece of wood, with a thin edge for the purpose, or a piece of iron hoop is a good substi-

tute; with these you carefully scrape off as much of the sweat or dirt as you possibly can, beginning at the top of the neck, and proceeding to the shoulders, chest, back, ribs, flank, hind quarters, belly, inside the arm and thighs, down the legs, &c.; when you have scraped off all you conveniently can, take him into a stall; then take off his bridle, and with clean wisps of straw give his head a good rubbing in every part; this should always be the first part rubbed after a horse has been out; it is exceedingly refreshing, and the horse as much as tells you so, for if you neglect it, he will rub himself against you, or any place he can get at. After rubbing his head well, put on the halter, and tie him to the rack, giving him a bit of good hay to amuse him, and then wisp him with clean straw, beginning and going from place to place as you would at other times, only let your wisps be loose clean straw, repeatedly changed as they get wet and dirty; the first wisping over you should rub both ways, to get as much of the mud out of the coat as you can, finishing with laying the coat smooth and close, that the heat of the body may assist in drying it the sooner; be mindful not to omit under the chest, breast, belly, under the flank, and between the hind quarters; these places not being so full in sight, are often neglected by ostlers and stable-men on the road; the legs must also be wiped down with wisps to take off the top of the dirt: having done one side, proceed in like manner with the other, and the first will be drying the while; after having in like manner wisped the other side, which is merely to take off the principal dirt, begin again, taking plenty of clean dry straw, and wipe him, for the purpose of getting him dry; if he is in good condition, and his coat short, you will soon get him dry; the wiping the coat down smooth will greatly contribute towards it, unless the horse is faint and weak, and breaks into fresh sweats by your rubbing; in this case apply the clean wisps with a lighter hand, that you may occasion the least perspiration, but not desist, though you will be the longer time about it.

Many readers will say, "my horses are not thus attended to, and yet I don't perceive any harm arising from it." This I will admit, that when horses have not been accustomed to thorough grooming, they may not be so liable to take injury on these occasions; but those that are properly groomed, not only are finer and

better in their coats, but more lightsome, active, and strong, for it, and able to go through more labour than they could without it; for this purpose grooming is necessary, and, being in the habit of it, a horse might sustain injury if neglected at this crisis, when it is most wanted; for which reason a good groom never leaves his horse till he is dry, and if he is a long time getting him dry, the horse will sustain no injury while he is rubbed, as it keeps the blood in circulation, and prevents getting cold.

Having got him dry with wisps or wiping (for some grooms are allowed coarse cloths like jack-towelling, for this purpose) proceed to brush him over as at other times, and finish the head, mane, and tail, rubbing the legs clean and dry, picking the feet out, and sponging the hoofs clean if necessary, thus making him as comfortable and dry as when he went out in the morning.

I think I have noticed the ordinary occurrences in the hackney stable, except trimming, which I consider the principal part of the groom's business, and what every one who has the care of horses should qualify himself to perform, as it is allowed to embellish and set a horse off to much advantage. Many horses are exceedingly troublesome to trim, and require extraordinary means to be taken to accomplish it, such as are shocking to relate; and I have known half-a-guinea given to trim such troublesome horses.—I am of opinion they were made so from improper methods taken at first, by those who had not patience to coax, nor ability to accomplish by compulsion, and who, therefore, made the horses desperate without fully accomplishing their purpose.—Most horses have such a dislike to be trimmed, particularly about the head, that few will stand without the twitch, and if they stand tolerably quiet with that, it is as much as can be expected; but if with a little coaxing it can be done without, it will be the better.

There is great care, skill, and judgment required in trimming: care, that you do no injury by the unsteadiness of the horse with your scissars—skill, that you may not disfigure him by scoring, notching, and the like—and judgment to trim in that style as will be most proper and advantageous. Begin, then, with the head, first with the foretop; you are to cut only that part of the forehead which is in the way of the front of the bridle and stall-collar, cutting it away close and

smooth; next clip away that part on the poll where the head-stall of the bridle or stall-collar comes, being mindful to clip as little towards the neck as you can avoid, for if you clip beyond where the head-stall of the bridle comes, you will disfigure the neck; you next come to as difficult a part as any, which is trimming out the ear, and few horses will stand quiet without being pinched with the twitch.

Good workmen will make shift with any sort of tools, and bad ones blame the tools for their own awkwardness; nevertheless, handy tools are to be preferred; the scissors for trimming ears will be most handy if narrow in the blades, the points not too picked, but should cut well at the point; begin with clipping the inner part of the ear, not cutting near the edges till you have got the long hair on the inside cleared out, and then gradually approach to the edges, shoving the outside skin of the ear back, that you may not clip so near as to leave the edge of the ear bare, which you would do if you did not take that precaution, and would shamefully disfigure the ear. The outside skin of the ear is very loose, and as you hold it with the left hand while you clip with the right, you are apt to draw it so forward that it deceives you; for you suppose you are not clipping near the edge; but when the hold is let go, you will perceive the edge bare, and this must be continued, or the ear will appear in scallops or notches, so that much care must be taken to guard against this error. When you are near the edges, you cannot be certain where to cut while you hold the ear, you must frequently let go to notice if you have cut far enough, carefully avoiding to take too much at a time; having clipped to the edges of the ear, and no farther, the outside hair will stand projecting beyond the edges of the ear, quite even and regular if you have been careful to clip it so.

At the bur and root of the ear, a deal of long flossy hair grows, which must partly be clipped away, that on the inside entirely with the scissors, and that on the outside you must be careful not to leave in scores and notches, leaving the singeing to accomplish what the scissors cannot so well effect. You finish with the scissors, by clipping round the edge of the ear the hair that projects, cutting it all round, so that you preserve the exact beauty and shape of the ear, being mindful not to notch or cut the back hair, so as to show the roots of the under hair, which will be a disfigurement; much at the root of the

ear must be left for singeing; the scissors will only score it.

You next clip all superfluous hair about his face and beard, which grows like a cat's whiskers, some under his eyes, about his nose, lips, and beard, cutting them close as possible.

Rough horses newly come from grass, and coarse-bred horses, have a quantity of superfluous hair growing very thick under the thropple and about the throat; this must be removed, partly by the scissors and partly by singeing; the longest and thickest part should be removed by the scissors; in the parts least in sight, be mindful to score as little as possible, for it is a difficult task to clip without scoring, and the hair is of that quality and so thick, that you might broil the horse before you could singe the scores out; therefore the greatest care must be taken to score as little as possible.

The fore legs are the next which present themselves, and the legs are sure to be particularly noticed, and consequently must have all pains taken with them; thorough-bred horses kept in stable, and properly groomed, seldom require trimming about the legs; all superfluous hair rubs off with their dressings; but when newly taken up from grass a little long hair will appear on the back sinews and on the fetlock joints, which may be taken off with a sharp knife; putting the blade under the hair, with the edge upwards, you press the hair between your thumb and the blade of the knife, and drawing your hand upwards, cut the hair that was so compressed to any length you please, which will leave no scores, and, if properly done, it will scarcely be perceived that they have been touched.

The coarser the breed of the horse, the more superfluous hairs will be found on the legs and within the pastern, and where it is abundant, it must be removed with the scissors; beginning next the heel, clip the hair out clean within the pastern, and under the fetlock joint, the adjoining part must be nicely tapered, that the sudden break from short to long may not appear, which it otherwise would in scores; for this purpose, put a comb under to raise the hair, and cut in such manner as to leave the outer hair the longest, whereby the mark of the scissors may not be seen. The soft spongy piece of flesh at the back extremity of the pastern joints, may be pared down, if necessary, with a sharp knife, and the hair next above left in such manner as to conceal it, being nicely ta-

pered off to resemble or appear like blood legs, or the legs of a blood horse; the hair up the back sinews must be raised with the comb, and cut in equal or even lengths, tapering the hair next the bone towards the sinew in such manner that no breaks or scores may appear, the hair next the back sinew being left the shortest.

Horses, like men, are not all equally straight: some horses are a little bent at the knees; where this happens, the hair within that joint must not be clipped too close, as it would make that defect appear more conspicuous, and trimming is to make the horse appear to advantage; therefore, care must be taken to conceal all the defects you can; but where the legs are straight, all the flossy hair within that joint may be removed carefully, minding to leave no scores with the scissors. Round the coronet of the hoofs the hair should be clipped, making it regular and even. The legs being thus trimmed, there only remains the tail for the farther operation of the scissors, as no scissors are ever to touch the mane, unless it is hogged.

Fashion and fancy are ever wavering, and the horse's tail and ears have been always subject to changes, agreeably to the taste of the times: at one time, a switch tail—at another, a full bushy tail—then a blood tail, and several others—and now a thin tail. I suppose that each of these fashions will again prevail at one time or other, therefore I shall notice each of them.

The switch tail required no cutting; the long hair left on the tail after the end of the dock was taken off, was pulled underneath, and at the sides, with an iron instrument made for the purpose, (but now seldom to be seen but in the carter's stables,) till they tapered it to a point, hanging about eight inches below the dock. There was much reason in this tail, for, since nature had accommodated the horse with a tail to cast the flies off, and fan himself with, man only took off the extremity, which he found annoyed him when the horse switched it about in hot or dirty weather, and left the horse all that could be allowed, so as not to incommode himself.

The bushy tail preserved all the hair it could, and, holding the tail to that elevation in which the horse usually carried it, the scissors cut in a perpendicular direction within about half-an-inch of the end of the dock. Scissors were made purposely for this business; the first sort were

made nine inches long in the blades, to reach to the top without the hand putting the hair out of place; but afterwards it was found more convenient to have the haft of the scissors bent like the gardener's shears, which they square the hedges with. There is much art and ingenuity in cutting these tails truly square, leaving both sides of equal length, and leaving no projections or hollows at the end. The carriage-horses are mostly cut so at this time.

The brush tail was suitable to those horses that, from being well nicked, carried their tails high, and bent upwards; these tails were cut rounding in such manner, that when their tails were up, they resembled the hair of a brush, and much ingenuity is required to cut them true and even.

The blood tail has been much in vogue for many years, and I think is as becoming as any. This requires the least art or ingenuity in cutting; you have only to comb the hair out, and, holding it together with your left hand, you cut the ends off square, at a proper length, generally about three inches below the end of the dock; then, combing the tail out, hold it up, and correct any irregularities you perceive. The hair of the blood-horse's tail is generally thin, and of an easy flowing nature, so that the tail cut in this manner is very becoming.

The thin tail is a mean representation of the blood tail; for half, and inferior bred horses, have fuller and more bushy tails than blood-horses; hence, to bring them to some resemblance of the blood tail, they pluck the under hair to thin it, and by that means make it appear like a thin ragged tail; the ends are squared as the blood tail.

Thin-tailed horses have been remarked in general to be good ones; whether the fashion was brought up to convey an idea of goodness, or to resemble blood, I cannot determine; but the difference is easily discovered, and I think they should be denominated ragged tails.

There only remains now to pull the mane and singe. First comb the mane thoroughly, laying it very smooth and even; then begin at the top, and, taking hold of a few of the longest hairs at the points with the right hand, separate them from the other hair by shoving the comb up; if you have hold of no more than, if bound together, would be about the thickness of a straw, twist them round the back of the comb, and pluck them out; then

combing the mane down again, take some more and pluck in like manner, till you have reduced that part to the thinness and length you wish; then proceed in like manner down the mane, till you have reduced it all alike, repeatedly combing it out, and any irregularities you perceive, correct, but not with the scissors; hairs left longer than the rest must be plucked, but not cut.

The foretop is a great ornament, and should be left long, so that it will tuck under the front of the bridle, and reach three or four inches below; the extreme ragged points may be taken off with the scissors, so that it is left thin at the points, but not squared to be thick and bushy.

Singeing now finishes the trimming business. Rough horses newly taken from grass, usually want much singeing all over, there being long downy hair projecting beyond the rest of the coat, which can only be taken off at the present by singeing, for it would be some time before the daily dressings would bring it off.

Begin with the head. For this purpose you have a candle with a large wick—a shoemaker's candle, that is made with two wicks, is best; the long downy hair which projects beyond the rest of the coat, may be singed to a level with the coat; these you will find in some parts more abundant than others—the outside of the ears will have some, much at the root or bur of the ear; the candle must not continue long in a place, to burn the horse; therefore, where there is much to singe off, you must rub the singed place, let it cool, and apply the candle again, but not to continue it so long as to blister the skin; the places that require the most singeing are at the root of the ear, the thropple, about the throat, and adjoining part of the neck; on the other parts, the long downy hairs will singe down at the first touch; but the places I have named, where the hair is thick and long, you must wipe the singed part off, and repeat it several times, minding not to burn the horse, which the thickness of the coat will prevent, unless you keep the candle in one place an unreasonable time, which you must be mindful of. Putting your hand over the eye, you singe all the light straggling hairs you perceive about his eyes, brows, forehead, cheeks, beard, and the like; where there is the least hair, you must be most careful not to burn, but the thropple and throat generally want many repetitions, the hair being so abundant and thick, and frequent

wiping to see that you do not singe it irregularly.

The head and throat being singed with the candle, the residue of the body is singed with straw. For this purpose you draw out some clean long straw, taking as much in your hand at a time as about the thickness of three fingers, and lighting one end, pass the flare or blaze from one place to another, beginning at his neck; be careful not to singe his mane; proceeding from thence to his chest, shoulders, breast, and every part where you perceive long downy hair projecting beyond the generality of the coat, minding not to make your blaze too large, nor continue it too long in a place, particularly where there is but little hair, as under the flank, and within the thighs, &c. Then giving the horse a good wiping and brushing over, completely finishes his trimming.

I have to observe, that horses having been kept for a time in the stable, and properly groomed, have not these long downy coats, and consequently will not require singeing all over the body; the beard, the ears, mane, and tail, are generally all that a blood-horse requires to be trimmed when he is kept in stable, but coarser horses will require the heels and other parts to be trimmed, though the coat may be kept so fine as not to require singeing.

I have observed, some horses are troublesome to trim. The means usually taken in addition to the twitch on his nose, or sometimes on the ear, are to gag them with the halter put through the mouth and over the ear, so that the more the horse struggles, the more he gags his mouth and pinches his ear; to keep the leg still while you are trimming it, a person should hold up the one while you trim the other; if a hind leg, a side line may be put on to draw up the leg you are not trimming; these are the usual expedients, but should only be put in practice when the horse cannot be coaxed to stand without them.

The most resolute and troublesome horse to trim that I ever saw, was secured in a stall with two strong halters, the one put on in the usual way, the other as a gag through his mouth; with these he was turned about in the stall, and one halter was tied to each stall-post so tight, that his head was confined in the middle, in such a manner that he had little or no liberty to move it in any direction; the consequence was, the horse made one resolute effort to extricate himself, but finding himself secured, and the gag punish-

ing him the more he struggled, he was cowed, and submitted to be thus held while he was trimmed. Plenty of litter in the stall is advisable, as it may prevent accidents in the horse's struggling.

**HUNTING STABLES.** After what has been said in the preceding chapter, there remains to be noticed the method to get your hunters into condition, and the care and management of them through the season. Hunters are usually turned into good grass after the season is over, and taken up generally in August, to be got in condition against the approaching season. Grass, if ever so good in quality, is not a substantial food; it is cooling and opening, and, though it makes horses fleshy, it nevertheless is not that description of flesh as the horse could work on; if you were to attempt to gallop him to that excess as you are necessitated when hunting, you would find the horse faint and weak; his flesh would melt or waste so fast with a white lathering sweat, as would most likely throw him into a surfeit, and kill him; therefore, the first thing to be done to alter this state of the blood, in the best, and most expeditious manner, is to bleed and physic.

No person has a greater aversion to bleeding and physicing than myself; I have been always in the habits of treating my own horses much after the same manner that I would myself, which was, never to take medicine unless I perceived an absolute necessity for it; for I have made a remark that all medical men that I have been intimate with, (and I have known several) have prescribed medicine to their patients for the most trifling complaints, but took none themselves unless they were extremely bad, and thought there was some danger. Judging I must be right in following their example, I therefore never take medicine myself, nor administer it to my horse, unless I am fully persuaded there is a real necessity for it, and then generally of my own prescribing, for I never apply to a doctor for ordinary or common occurrences.

In the case of a horse being taken up from grass, they are generally very full of blood, and inclined to itch and rub themselves much; and not only in this, but at all times when the horse rubs himself much, bleeding may be necessary. The first thing, therefore, to be done, is to get him shod, for horses usually have their shoes taken off when turned to grass, and if not, they generally loosen them

before they are taken up; then take about two quarts of blood away, and let him stand quiet without any food of any kind for three or four hours. While he is full of grass he will not drink much water, but after living a few days on dry food he will drink plentifully if you will let him; there is no necessity for your stinting him in water, till he has been through his physic. If he can be taken up from grass by degrees so much the better.

His coat will be exceedingly foul and full of dirt and nits, therefore he will require some good dressings; the opening his coat and taking the dirt out, will require him to be clothed; buckle a cloth on with a good broad roller, pretty tight, to help to get his belly up; after he has been in stable three or four days, and emptied the grass out, you may give him his first dose of physic, preparatory to which, the night before give him a cold mash, consisting only of bran moistened with water—this, and hay, is the only food necessary till his physic is set, as they term it, that is, done working; were you to give more substantial food, it might lessen the effect or operation of the physic, or be thrown out whole and undigested; consequently, it is best not to give any. Give your physic the first thing in the morning, and if your physic is good, it may be expected to operate from twenty-four to thirty hours after giving.

I do not mean to give any prescriptions for physic, lest I should be accused of meddling in a profession I have not taken up my degrees for at the Veterinary College; scarcely a druggist but what prepares horse-medicines, and every veterinary surgeon has them in dozens, ready made up for immediate use; but should any gentleman have a favourite prescription, which he prefers for his own use, I will not dispute the goodness of the prescription, but I must caution him to be certain that the quality of the drugs of which it is compounded, are genuine and good; I don't know a more serious evil than the compounding of medicines with bad drugs, and I have experienced the evil in the country, when I have sent a prescription to be made, for, whether from ignorance of the quality of drugs, they might have been imposed upon themselves, or whether from avarice, thinking a cheap or spurious article might do for a horse, I won't pretend to say; but physic prepared with bad materials not only deceives and dis-

appoints you, but may do infinite mischief, even the loss of a horse perhaps worth a hundred guineas, or more; therefore I recommend you to procure your physic of persons who are respectable, and prepare great quantities; it is likely from their using large quantities, that it is not prepared with stale drugs, and also from experience they are judges of the quality; but giving a horse-prescription to an apothecary, or a country druggist, it is likely to be made up of drugs that have been years in his shop, and perhaps originally not of the best quality.

By the continued use of one person's physic, you will become acquainted with its strength and quality, and may, if you think necessary for either small, young, or weakly horses, diminish the dose, suitable to the constitution you give it to.

Every groom should be expert and handy to administer and apply the common and ordinary recipes to a horse, and perform the common operation of bleeding; the frequent sight, and assisting at these operations, convey the best idea of them; nevertheless, there is an art in giving a horse a ball, which a looker-on cannot easily discover, and it being a material thing to give it well, I shall point out such particulars as may assist the young practitioner.

The generality of things may be done with deliberation, but the giving a ball must be done expert and quick, if not, it becomes disagreeable to the horse and difficult to you; a balling-iron is used by those who are not expert at it, and it may be best for those not in the habit of giving balls, but those accustomed to give balls will do it as well and sooner without.

First, you should be certain you are tall enough to reach, should the horse raise his head, before you make the attempt, and if not, stand on something to raise you. Let the person who holds the horse, have the ball ready to give you, if you are necessitated to use both hands to get hold of the tongue, and place it as I shall direct. Stand before the horse, and take the farthest hold you can of the tongue with your left hand, drawing as much out of his mouth as it will admit, and in such manner that your thumb is in the mouth, placed on the near side of the tongue, and pressing it between his grinders, which effectually prevents him from shutting his mouth; folding your right hand in as small a compass as you can, hold the ball at the extreme end with the three first fingers, and put it over the

root of the tongue into the gullet, thrusting it as far as you can reach with your fingers; then let go the tongue, and bridle the nose in, to prevent his attempting to cough it up, till you see it pass down the gullet; you must attentively watch this, for you cannot be certain of his swallowing it, unless you see it pass down; if he hesitates to swallow, hit him on the gullet with your hand, and that will occasion him to make a gulp; for some horses will, if you are not mindful, hold it in the gullet till you loosen the head, and then cough it up; or if you have not properly put it into the gullet, but lodged it at the extremity of the grinders, you will perceive him chewing it, and put it out of his mouth. I have seen awkward persons spoil several balls before they could put one fairly down; if you are awkward, the horse will make the more resistance; but if you are expert you pop it down without inconvenience and disturbance to the horse.

When you have given the physic, you need not take him out of the stall till it should begin to operate; hay, or bran moistened may be given him, if he will eat, but the physic mostly occasions sickness, and he refuses to eat. Water may be given as much as he will drink; warm water will occasion the physic to operate the sooner if he will drink it; but cold water, or such as has stood in the stable some hours, which takes the raw chill off, will not hurt him, if the physic is prepared without calomel, or other preparations from mercury; which should only be given in certain or obstinate disorders, worms, &c. on which occasions no cold water should be given, and extraordinary care taken not to expose the horse to take cold, but with plain physic there is not that danger; nevertheless, you are not to strip his cloaths off, nor dress him till his physic has done working, or his dung set, which in general will be about the third or fourth day.

At the period his physic is, or should be, operating, you may take him out and move him about, in a walk or gentle trot, but not so much as to heat him, to promote the working or operation of the physic, and let him drink as much as he pleases; but you are not to strip any cloaths off, but rather throw an additional cloth over him, for warmth promotes the operation of the physic, and cold will check it; therefore, the walking, or moving about you give, should be in a dry and warm place; when the physic has operated once or twice, put him

in ; you may wipe his legs clean, or any dung off his houghs or hind quarters, but not give him any rubbings, for that would loosen the coat, or open the pores, which might subject the horse at this period to take cold, and stop the working of the physic.

When the physic has so operated, as to keep the body open for about twenty-four hours, giving him copious and loose stools, you may forbear using means of promoting further operation, and let him stand till his dung is set ; you may then give him his corn, strip and dress him well, and the next day take him out to exercise.

About the sixth or seventh day from the time he took his first dose, you may administer the second dose, ordering the horse in the same manner as I have directed ; and again letting the same time elapse between, you may give the third dose, which in general is sufficient to thoroughly cleanse the horse from that faint or foul condition which green food naturally occasions ; and then you will, by proper diet and exercise, get him into wind and condition fit for hunting, but before I proceed with that part, I shall make some farther remarks on physic.

I have noticed the manner of ordering a horse in physic, under the circumstances of the physic properly operating and going on right ; but from various causes it may so happen that physic does not take a proper or the expected effect. If physic does not operate in the space of thirty-six hours, some reasons should be assigned for it ; it may proceed from the quality of the physic not being good, or it might so happen that the ball was not completely administered, for when a ball is awkwardly given, and the horse gets part of it in his teeth, he may only swallow a part, which you perceiving to pass, may be therewith satisfied, and the residue may be dropped in his litter, and never after discovered ; or it may proceed from the habit or constitution of the horse not being easily moved, so that he may require a stronger dose ; and some horses will keep physic longer within them before it operates than others. Whatever the reason may be, I should not be in haste to administer another dose till I had used the ordinary expedients, and waited to observe the effect.

When physic does not operate in the space of thirty-six hours, keep the horse warm, for that will assist the operation, and warm a quart of mild ale, and give it to him with a drenching-horn ; or it can be as well given out of a bottle, if you

have not a horn at hand, minding not to give it too hastily ; and a quarter of an hour after let him be gently moved about in a trot, but not to heat him ; at night give him a warm mash, with a handful of ground malt in it, and if it does not operate the next morning, I should then be inclined to doubt whether he had really taken the physic, unless the horse had been sick, which you will perceive by his being dull and heavy, and refusing his hay : on the other hand, a soft stool only, may be in consequence of the warm ale or mash you might give him ; but if he throws out a copious thin stool, having been sick with it, you may conclude he had his physic all, or in part ; yet, if his body is not kept open four-and-twenty hours, having several copious stools, I consider his physic not to be sufficiently strong, and should increase my next dose accordingly, for in general the first dose of physic operates the most, and I usually take a small piece off the first dose to add to the last, if I think necessary, and particularly if I know not the constitution of the horse I am administering to, it being safer to under-do it, than over-do it ; and by the second dose I can very well judge what his constitution will bear, and proportion my dose accordingly.

On the other hand, it sometimes happens that physic is too powerful, owing to various causes—sometimes the constitution or habit of the horse's body, is weaker than at other times ; and sometimes the physic may be composed of stale drugs, such as have lost their balsamic quality, but retain the purging quality, which is exceedingly injurious ; in these cases you will observe the horse purge from the anus, throwing only part of his stool from him, and an involuntary discharge issuing from the anus, running down his hind quarters underneath, and all down his houghs and legs, in a continual wet and slimy condition ; you must then keep the horse still, and be mindful not to let him take cold, wiping him as dry and clean as you can, for the stool is of a very sharp acrimonious quality ; if you find the purging does not abate in its due course of time, proper remedies should be taken to check it ; rice gruel may be given him for drink, and if he is disposed to eat the rice, you may let him ; you must desist from giving him bran mashes, but give him dry and heartening food, if he will feed ; should the purging still continue, you may mull a bottle of red port, with plenty of cinnamon or cas-

sia, and when sufficiently cool, give it him as a draught with the drenching horn—this will most likely check the purging, if not, you may repeat it. An ounce of gum-arabic should be dissolved and given in his water, which will heal and strengthen the coats of the stomach, if impaired by the excessive operation of the purging medicine. When the purging has been thus excessive, I should let a clear week elapse from the time the dung was set, before I gave another dose, to let the coats of the stomach recover from the injury they may have sustained; giving the dissolved gum-arabic in his water for that purpose. You will consequently be mindful that your next dose shall be less in quantity, or of a less injurious quality.

Horses having gone through their physic, you proceed by proper exercise and diet, to get them into wind and condition for hunting. Your physicing has taken between three and four weeks to get the horses cleansed from their soft foggy food, and now about the same space is allowable to get the flesh firm, the coat clean, the limbs supplied and strengthened by exercise, and the wind improved by suitable management of diet and exercise for that purpose.

As you have been at so much pains to cleanse the body from soft and foggy food, you must now be careful that nothing but clean wholesome food shall be taken by him. For this purpose you should be provided with a rack-rein and muzzle, which must be alternately used—when the one is taken off, the other is to be put on; for instance, you put on the muzzle when you wish or expect the horse to lie down, (or, if he be inclined to bite, when you dress him;) this is to prevent him from eating his litter, which some horses will do even when it is very foul, and when fresh litter is given, many horses will prefer it to their hay; and though clean straw is not injurious to horses that are not required to gallop much, yet hunters and racers are not permitted to eat it, because it oppresses the wind. The rack-rein is an iron chain fixed at the head of the stall, which passes through a ring sewed in the front of the nose-band of the stall-collar; it is fastened in the same manner as a dog's chain to the ring in the collar, and when dressing the horse, you can, after passing it through the collar, fasten him as short as you think necessary; but at other times the chain must be long enough to

permit the horse to feed out of his rack, or out of his manger, though not to let his head reach down to his litter.

The first thing to be done in the morning at coming to stable, is to take off the muzzle, and put on the rack-rein; then throw into the manger about a quart, or a little better, of oats, according to the stomach or constitution of the horse, for some are puny feeders, and must be treated in such manner as will best invite or occasion them to eat, while others, on the other hand, will eat all you set before them, and must be stinted to a proper allowance. The oats for these occasions, should be the best that can be procured—dry old oats, short and plump, clean from all manner of seeds, which are frequently to be found, particularly among foreign oats, perfectly sweet and free from dust, and white as a hound's tooth; sift them well, and blow the husks, chaff, or any light oats away, and be sure to keep the manger very clean; when the horse has eaten his oats, during which you will just clear his dung from behind him, but not to disturb the wet litter, as to occasion the vapour or stench to arise, you may strip off his clothes, rub the dung, if any, off his hind quarters, hocks, &c. and giving him a light brush over, put on his exercising-cloth and saddle; then turning him about, brush his head and ears, put on his bridle, and take him out for exercise. The stripping and brushing I look upon to be as refreshing to the horse as your washing when you get out of bed in a morning. While the horses are out at exercise, a person should be left at home to clear away all the wet dung immediately, setting the door and windows open, to get the stable sweet against their return, and all the stalls set fair, and the stable cleanly swept.

For exercise, choice should be made of the driest and most open piece of turf, sod, or heath that is in the neighbourhood, and likewise where there is some gradual ascents, if of half a mile or a mile in length the better, to give the horse some gentle breathings, to bring him in wind. You should walk them the first half hour, letting them empty themselves, yawn, stretch their necks, and enjoy the sweet refreshing morning air, which is uncommonly bracing and strengthening both to man and beast; so manage your walks as to bring your horse about this time to a convenient place to give him a gentle gallop; begin slow, and gradually increase your pace till you finish at a half or three-

quarters speed; proportion the length of your gallop according to the strength or condition of the horse; if he is faint, so as to sweat soon, stop in time, and walk him to take breath and cool himself, for you are not to put him in a thorough sweat, but on those days which you appropriate for that purpose; which should be about twice a week till he commences hunting, and then he will not require any sweating in exercise; in this manner alternately walk and gallop, (so as not to sweat the horse,) till you find it time to return, which you should so manage as to keep the horse out about two hours, and after the conclusion of the last gallop, and the horse has recovered his wind, and is cool, you should contrive to have water at hand to let him drink, and then have half an hour's walk home. If the water chills him, and makes the coat stare, a gentle gallop to warm him will be proper, but not to sweat him.

Horses are most fond of staling on litter, as it does not then splash them; and if the wet litter was spread in a convenient place without the stable, (some yards are strewed for that purpose, and for making dung) the horses standing a minute or two before they are put in the stable, will stale, and thereby keep your stable clean and healthy. When put in the stable, a bit of hay should be given that has been well shaken from dust and seeds; the quality of hay for hunters should be the choicest that can be procured, grown on a rich meadow, and cut before it gets too ripe: for hay, when it stands too long before it is cut, may answer the farmer's purpose by seeding his ground, and wanting less making, but for the good of the horse, it is preferable when cut young before it seeds, and with the sap in; then if it is well made, and got in dry, it will, fourteen months after, cut out as green as a leek, and the flowers retain their beauty nearly as when growing, and hay will never be better than when twelve or fourteen months old, but such hay as this is rarely to be got; yet, hay off good meadows, that has not been heated too much in the stack, is to be got; some admire it to be a little brown, but I think if it is twelve months old, having a fragrant sweet smell, it cannot be too green. New hay must on no account be given; there is a faintness in new hay that would be as detrimental to the horse as giving him grass.

The first thing after putting the horse to his rack-rein with a bit of hay before

him, is to go down on your knees and wisp the legs, for the legs are always to be the first and last things attended to, and particularly after physie; then strip his cloaths off, and give him a thorough dressing, agreeable to the manner I have directed; after which, give his feed of oats, being double the quantity, or nearly so, to what you gave before going out; then having wisped his legs as the last thing, shake up his litter, and set the stable fair; if he has cleared the rack of the hay, (for I always recommend to give but a little at a time, that he may eat it with better appetite,) you may give him a bit more if you think it necessary, but never give more than he will clear with a good appetite.

According to the time that you should come to stable at this part of the year, which, we will say, is five o'clock, it will now be time for you to breakfast, (I suppose between eight and nine o'clock) and you may leave the hunters on the rack-rein while you have your breakfast, and they finish their hay.

At your return to stable, observe that all have cleared their racks, and if they have had sufficient time, and the racks not clear, take it away; loosen the rack-reins, put on the muzzles, and leave them for four hours to lie down if they will—it is a desirable thing for horses to rest their legs at all convenient opportunities.

This will bring the day as far advanced as two o'clock; when the days get short, you must be at stable sooner, so that you may contrive to be at home from exercise before dark. You should proceed now in like manner as in the morning, putting on the rack-rein, giving him a mouthful of hay, and a feed of oats in moderation; for you are not to fill him, or encumber him with food, particularly hay, when you are going to take him out. While the horse is feeding, clear the dung from behind him as in the morning; then strip and brush him over, previous to putting on his exercising-cloth and saddle, and take him out as in the morning. If you are situated in a country that affords a variety of suitable places for exercise, vary your places as often as convenient, it will be the more agreeable to both man and horse; and keep off the gravel road, choosing to go on the turf as much as you can; having been out about two hours, in which time you have given him two gentle breathings, you may let him have water, and return.

The stable, as before, in your absence,

should be cleared of all wet litter, and aired and refreshed against your return. After giving the horse the opportunity to stale, bring him in the stable, and repeat a rubbing of legs, and thorough dressing, having a mouthful of hay in the rack to amuse him; after his dressing, give him his feed of oats, and a bit more hay, if he has cleared the rack of what he had at coming in; this will bring you to about five o'clock in the evening, at which time you may leave him on the rack-rein to eat his hay, and at eight return to finish for the night. If you gave him a sufficiency of hay at leaving stable at five o'clock, he will need no more, the horse having had three hours to feed with hay; if he is a slow feeder, he ought to have cleared his rack by this time, and those that have not, I should take it from them; for the horse will have no appetite for hay that is glutted with it, and has it always standing before him, and you should always be mindful not to give too much, so as to cause him to leave any. You have now to feed with oats, for the last feed; see that all their clothes are proper, not got atwist, and the like—that every horse finishes his corn, not leaving any; then loosen the rack-rein, put on the muzzle, and making up a good bed, having plenty of dry litter, and a large stall to lay his legs out at length, leave him for the night.

This is the daily routine of the hunting stable, without any material difference, except on the days appropriated for sweating, which must be at least two days in the week till the hunting commences, at which time, if the horse is hunted twice in the week, there will be no occasion for sweating exercise.

I do not recommend hunters to be kept over-warm with clothes; they are exposed frequently to cold and wet, and the more tender they are kept, the more likely they are to take cold; therefore, hoods and fillet-cloths may be dispensed with: but I think it necessary that each horse should have two cloths, one for exercise, which will occasionally come home wet and dirty, and the other for the stables. Your cloths should be occasionally scoured, and your exercising-cloth as often as it gets damp by rain, sweat, or dirt, carefully dried.

On the days which you give your horses sweating, which may be on Tuesdays and Saturdays, or any other days equally distant, contrive to give his sweats as contiguous to home as you can, particularly if

the air should be thin and piercing, for the purpose of getting home to scrape and rub him dry; for when a horse is in a thorough sweat, a chilling air penetrating under a wet cloth may give him cold; therefore, the stable, or rubbing-house at hand, will be convenient to rub him dry, and prevent such a circumstance.

After having walked the horse for about an hour, bring him to the place where you intend to gallop him, and begin very moderately, gradually increasing your speed till you get him to half, or three-quarters speed, if he is hard to sweat; at which rate you may continue him, till he is in a proper sweat, which will be sooner or later, according to his condition; if he is fleshy and foggy, he will sweat soon, and his wind will be distressed; in this case you may gallop the slower, not to distress the wind, but bring him to a sweat, which will waste his abundant flesh, and bring him in wind as the flesh diminishes. If you find him in wind, and hard to sweat, his condition is the better, and you may gallop him the stronger without injury.—The meaning and intention of these sweats is, those that are in wind, to keep them so; those that are not in wind, to get in wind; to waste all superfluous flesh, and get the carcase up; throw out any foggy grossness remaining in the blood, by perspiration; it likewise cleanses the coat, making it sleek and soft, for the imperceptible perspiration continually issuing through the pores, adheres so closely to the roots of the hair or coat, that it is not easily got out; but these profuse sweatings bring it away, and you will perceive the coat to be finer when well dressed after a good sweating.

The condition of the horse is to be discovered and judged of by his sweating; if he sweats soon, and the sweat ferments into a white lather like soap, he is foggy, and must have strong exercise to bring it away; if he requires strong exercise to bring him to a sweat, and the sweat is clear like water, and dries soon, he is in good condition; but if he sweats profusely with little exertion, and the sweat, though then like water, is a long while drying, it shews a faint weak habit of body, which, with some horses, is constitutional, and such will seldom stand excessive hard days' hunting. Some horses sweat more profusely than others—this is not to be regarded as weakness, if it proceeds from strong exercise, and soon dries; constitutions differ in horses as well as in men.

The horse having had his sweating gallop, should be brought into the stable or rubbing-house, and be scraped and rubbed dry with all possible dispatch, and a clean dry cloth put on him; not the one in which he was sweated, which should be got clean and dry against it is wanted again. If he had no water while out, you may give him some after he is perfectly cool and comfortable; and should the weather be very cold, the chill should be taken off, but not made warm; water that has stood several hours in a warm stable is sufficiently chilled, and may be given him; or you may, after rubbing him, walk him about, give him water, and gallop him gently to warm it, but not to heat him—then bring him home.

A horse treated in the manner I have directed, will, in three or four weeks after having been through his physic, be fit for hunting, if proper regard is had to his feeding. His food I have directed to be of the best and cleanest quality, and the quantity must be regulated according to circumstances, such as size, constitution, and the like; now the horse's daily exercise will be on the average not less than twenty miles per day; with this exercise the quantity he eats will not hurt him, if he does not get too fat, for the horse, for hunting, must have plenty of good feed in him, but must not be burthened with flesh. If he feeds heartily, he must have strong exercise to keep his flesh down, and his body up; if inclinable to have much belly, and be fat, he must be stinted proportionably; but when he comes to hunt twice or three times a week, there will be no occasion to stint him—he will never be burthened with flesh with such exercise.

The horse being got in condition, and the hunting commenced, you are relieved from that part which regards the sweating, and instead of giving exercise to keep the horse's flesh down, and give him wind, your exercise is now for the purpose of walking off stiffness, occasioned by over-exertion, bracing the system that has been relaxed by excessive exercise, and creating appetite; hard running and long distances, continued for many hours, will consequently affect horses more or less, particularly at the beginning of the season before they are accustomed to it, so that their appetites will fail as well as their limbs be stiff; and your attention is now to recover the horse from that languor and debility occasioned by over fatigue.

Young horses, and those not seasoned to hunting, though in condition, are mostly affected by severe days, and such must not be expected to hunt more than one day in the week, for it will take nearly that time for them to recover from a hard run, either with fox or stag; but seasoned hunters will stand hunting twice a week, and some three times, though that for a continuance, I think, too much for any horse to stand, unless it is with harriers only, where there is seldom much hard running.

Now, to order your horses when they hunt, you feed and dress much after the same manner as before directed, only when you know of going out in the morning, rather shorten your allowance of hay in the evening, and increase his corn, but not so as to gorge him. He should always have a good bed, to invite him to lie down, and stretch his limbs, and his muzzle should be on; for though many do not constantly use the muzzle, yet, if it is used at all, it is most proper at this time. In the morning put your horse on the rack-rein, but no hay before him; this is what I have recommended to be your constant practice; for if you make it a rule not to give hay till he comes home from exercise, the horse will not pine or look for it. If you are going a great distance to meet the hounds, or to cover twelve or more miles distance, you may give him a moderate feed of oats; but if you are going to turn out a deer, or expect to find near at hand, let the horse go out perfectly empty, and on no account give him any water:—If I washed his mouth, it should be from a bottle from which I should be certain he could not drink more than a pint; let him be thoroughly cleaned, and his legs well rubbed, and his saddle on, moderately girthed, at least an hour before going out; this will cause him to empty himself; for if you observe, most horses, when the saddle is put on, dung if they can; a quarter of an hour before wanted, put on his bridle, and have him perfectly ready; buckling him to the stall-reins, let him stand till wanted, with a cloth thrown over the saddle.

When horses come home from hunting, it necessarily follows that all expedition should be used to get them clean, and make them comfortable; if there has been hard running, and the horses come home leg-weary and tired, cleaning will be more refreshing than feeding, and therefore must be first attended to, not but the

horse may have a bit of choice hay put into his rack to amuse him, if he will eat while he is dressing; but when it has been a long day, and hard riding, many horses will be off their feed, particularly young and unseasoned horses; this, as a matter of course, is to be expected, though it is most to be desired that the horse should feed, which shews a fit constitution for extraordinary labour.

After a thorough cleaning, in which you must be particular to rub his head and ears well, and get him dry in every part, making him as clean as when he went out in the morning, you should carefully examine him all over, to see if he has received any injury from stakes, stumps, boughs, brambles, thorns, rails, flints, &c.; likewise that he is not galled with the saddle, girths, or breast-plate, if he wore one. When the horse has been refreshed with a good cleaning, he will be more inclined to feed than before, but if he will not, make yourself easy, for his appetite will return as his weariness wears off.

On returning home from hunting, it is not uncommon to let the horse drink at some convenient pond; the horse should not be suffered to drink too much at a time, which his extreme thirst might induce him to do, but letting him have about a dozen gulps, ride on to another convenient place, and let him have the like quantity; and thus, by degrees, let him quench his violent thirst before he comes home, which will be better than letting him drink a vast quantity of cold water at once; should this have been neglected, he must have water with the chill off, but not warm, and when his thirst has been partly quenched, he probably will eat.

The legs, from excessive labour, will, of course, be weary, and often inclined to heat and inflammation, particularly if he has been rode among brambles and thorns, the greatest attention must be paid to them. Hot water should always be ready against horses come in from hunting, for the purpose of washing their legs, for nothing is more refreshing to our legs and feet, when they burn with heat and weariness, than soaking in warm water; it opens the pores, and draws the heat and inflammation away, and will be found equally as salutary to the horse as to ourselves. Let the water be hot, but not to scald, or endanger bringing the hairs off, and bathe the legs with it, having a piece of old rug for that purpose, which will

hold much water and heat, and may be laid round the fetlock-joints and pasterns to foment, and draw out heat and inflammation, dipping it occasionally in the hot water as it gets cold: after fomenting the legs well, wipe them as dry as you can, first with a sponge, and carefully search with your hands if any brambles or thorns are lodged in the skin; for your feeling will discover what your eye cannot perceive, and the pores being opened with the fomentation, they will be the more conspicuous, and less difficult to get out. Whatever you discover of this kind, must be picked out with care, so as not to enlarge the apertures they have made, nor break or leave any part of them in; for what is left in must occasion heat and inflammation till nature has expelled it, which she will do by discharging an ichor from the apertures, and thereby thrusting them out, so that scabs and scratches will appear where they have been; but, if carefully taken out in the first instance, much pain, heat, and scabs, will be prevented.

I have known thorns to penetrate deep, and break within the skin, and if such are not discovered and taken out, they will fester, and perhaps form a large abscess; an instance of which occurred with a person I knew, and the ignorant farrier opened it at the upper part, and put therein a tent of lint, dipt in tincture of some kind, most likely myrrh and aloes; had he opened the abscess at the bottom, the pus could have discharged without lodging and corroding the wound, nature would have done the rest, and the wound would have healed without a blemish; but, as it was, a fleshy substance grew within, occasioned by the tent, and though it was after a while healed, it was ever a blemish and eye-sore. I mention the above, to shew the necessity of carefully examining for thorns, and should a similar disaster happen, be sure to open the wound at bottom, so that the pus can discharge itself without lodging, and nature will do the rest, if you do not obstruct her; to assist her you may press the matter out, which will also press the skin down, and prevent the flesh growing inside, which it might do if the wound was kept hollow.

Having carefully searched, and extracted all brambles or thorns, wisp and wipe the legs perfectly dry; and when he is thus refreshed and had his water, if he will not feed, it is most likely for the best, for extraordinary exertion, more than he

has been seasoned to, occasions an inward fever, and till rest and air have contributed to abate this fermentation of the blood, the appetite will not return. Some make themselves uneasy on this account, and wish to administer something; many are for giving a warm mash, which the horse will not eat; then a comfortable warm drink (as they call it) or a cordial ball, all of which is of no service; a dose of physic would be better, or taking some blood away, but I recommend patience till the next day; make him up, therefore, a good bed, and leave him to rest and stretch his weary limbs till the morning.

In the morning I make no doubt you will perceive the horse will feed a little; you must then proceed as before directed, and take the horses out to exercise—those which have been hunted, only to stretch their limbs, which may be stiff and sore, as we find ourselves after any extraordinary exertion, which we are not in the frequent habits of, and repeating it in moderation, will contribute greatly to take off the stiffness—so with the horse, the moving him about will gradually wear off the stiffness, and the fresh air will recover the lost appetite. Though I term this walking exercise, I do not mean you are not to exceed a walk the whole time you are out; that, perhaps, if the weather was very thin and cold, might increase the stiffness; but I call that walking exercise which puts the blood in free circulation without over heating it; you may, therefore, give the horse a gentle canter for a short distance, but not to cause him to break out in a sweat; particularly after giving water, gallop by way of warming it. Choose the airiest place for exercise, such as open downs, or high and dry grounds, and at your return to stable, your horses, if they were not very sick indeed, will find their appetite.

Horses that weary and sicken at a day's hunt, which may be the case with good horses at the first of the season, or young horses till they get seasoned, will require some days to recover before they are fit to hunt again; a week's respite may be necessary with some, others will recover in half the time. The sooner the horse comes to his appetite, the sooner he will be fit for labour; provided you have not been nursing with warm mashes and comfortable drinks, which relax and open the body, and should only be given when the horse is in reality ill; but loss of appetite from over-fatigue, only requires rest to recover it;—slops and medicines

will not hasten the cure, but will unbrace or weaken the system, rendering it less fit for labour, and more liable to a return of the malady, with increased symptoms, the next time the horse hunts.

With regard to heat or inflammation, from the saddle or girths, washing the part with goulard is equal to any thing I have seen applied, and the legs, if hot and swoln with fatigue, may be washed likewise; it is a great repellent and cooler, and should always be kept ready on such occasions. Get the extract of lead from the chemist's, and prepare a quart bottle full at a time, and keep it for use. The manner of preparing it is, to put no more of the extract than will just turn the clear spring water to a milky white; whatever quantity of water you have in the bottle, put the extract to it by drops, shaking it, and when it is turned white there is sufficient; if you put more than sufficient, it will be less and less white, and consequently too strong. Some put a small quantity of brandy to it, which is optional—I see no occasion for it.

The washing the legs with the goulard, will heal or dry the scratches of thorns, and the small apertures they have made, and repel the humours from flying to them, and prevent scabs and the like.

The feet are likewise to be attended to at all times. The horse should never go out of the stable, but, at his return, all road dirt should be picked out, and the feet examined, that no gravel is lodged under the shoes, for such in time would become tender, and cause lameness. When you wash the legs with warm water to cool and refresh them, it will also cool and draw pain out of the feet; water is beneficial to the feet; we find the feet less injured by travelling on wet roads, than on dry ones; and the hoof, at grass, being continually wet with the dew, and moist ground, is in a better state than when kept in the stable; the casual wet you meet with on the roads, or the moisture of the turf or grass you exercise on, will contribute to preserve the foot from the injury which continually standing in a hot and dry stable occasions—one half of the pleasure horses in London are ruined by standing so much in the stable.

In your daily attendances on the feet, you must take notice of the shoes. In the first place, observe that they are all fast, and not worn too thin, and the clenches all flat and smooth, or the shoe broke, as they will be sometimes when worn thin, and the iron bad; that the shoes have

not got into the heels, or sunk in the feet, as they will when horses have not sufficient work to wear their shoes out, before the feet grows over them; in this case the shoes must be taken off to have the feet pared, and put on again, which is called a remove. The ignorance and obstinacy of the old practitioners in farriery were difficult to overcome, but at length have yielded to the superiority of study and science. The anatomy of the horse's foot is clearly understood, and the benefit we derive from it, cannot but rejoice those who recollect the number of valuable horses that were crippled and spoiled by ignorance and error in shoeing. The post-horses, staggers, and hackney coach horses, were comprised principally of crippled horses, or such as were termed groggy in the feet; the poor things stood with their feet forward in the greatest anguish, shifting from foot to foot alternately, for a little ease, and their very countenances were expressive of extreme pain; now, comparatively few such are to be seen. With care the foot is preserved to the last; whereas, formerly, a young fresh horse from the breeder, in the space of two years, his feet getting gradually worse and worse, became unfit and unsafe for a gentleman's riding, and, in his very prime, was cast off to hard labour, rendered more intolerable by unceasing pain.

But, though the improved system is now almost become general, that every person employed in shoeing of horses, knows how it ought to be done, nevertheless, there should be exactness and care which some men will not observe; it may be necessary to apprise the man who forges the shoe, if the horse is apt to interfere, which is called cutting, and likewise if he over-reaches with his hind foot, striking it against his fore-shoe, which is extremely unpleasant; these things may be greatly assisted, or totally prevented, by making and placing the shoe accordingly. The interfering is remedied by leaving the inner heel as high as you can, and paring the outer heel down in moderation; the inner heel of the shoe is made thicker than the outer; this raising of the inner heel throws the fetlock joints outwards or wider apart, which, with that part of the toe that is liable to interfere, being pared close, and the shoe no wise projecting, will prevent the interference, or what is called cutting.

The hind-shoe striking against the fore, which some horses are apt to do, is pre-

vented by shortening the toe of the hind shoes, and not letting it project beyond the hoof when rasped to the shoe, so that if the toe struck, it would be the horn of the hoof that would strike, which will not make that unpleasant noise, which is beyond bearing.

When horses newly shod or removed, go unpleasant or unsafe, which before went safe and well, as is frequently the case, it is reasonable to suppose that the shoes are put on uncomfortably. I have had horses that have gone as if crippled, and have been apprehensive of their falling every step; the shoes, to all appearance, seemed well put on, and no appearance of the nails being too far in, so as to press on a vein, or the like: the cause of this I apprehend to have been, the shoe had only a partial, and not an equal, bearing on every part; the parts that had not a bearing, from not being solid, the driving and clenching drew the hoof to the shoe, which must render the horse extremely uncomfortable. I think these cases are most likely to happen, where you caution them not to put the shoe hot to the foot, for it is difficult for them to fit the shoe to the foot, and be certain that it touches and bears equally on every part, without just applying the hot shoe; and though I do not approve of the shoe being so hot as to sear the foot to fit the shoe, yet the application of the shoe moderately hot, (to show where the shoe bears, and were it does not, that the knife or rasp may take down such places till the bearing becomes equal) is a less evil than putting the shoe on at a hazard, where there is not equal bearing all round. The driving the clenches down over much, may cause pain and uneasiness, but it is not so likely to pinch when the shoe sits solid, as when it does not.

When occurrences of extreme uneasiness happen immediately after shoeing, I recommend the shoes to be immediately taken off, and, though the farrier may insist nothing was amiss (for we are none of us fond of acknowledging an error that cannot be brought home to us) yet he may be careful to remedy the cause, whatever it may be, whether from the shoeing being too tight, or a nail struck too far in, unequally bearing, or the like. Not that you are to expect horses with bad feet will go as pleasant in new shoes as old; those with thin flat feet, and such as have been shod after the old system, having the bars of the feet pared away, and the heels contracted, will, till the shoes have

got settled to the feet, go more tender and unpleasant.

The substance and weight of the shoe should be proportioned to the work and employment of the horse; never load the foot with more iron than is necessary to preserve it; if the horse's foot is light, let his shoe be light also, and if he works principally on the road, his shoes should be somewhat stouter.

The casual incidents that occur should be attended to, such as bruises, pricks, kicks, treads, and the like, which, if not very material, may be administered to, and cured without the aid of a veterinary surgeon; the injuries the bottom of the feet sustain, are generally from picking up nails, bruises on sharp flints, broken bottles, stumps of trees, and the like; these generally require the farrier to take off the shoe, and examine the wound, that nothing is left in, and a dressing of their hot stopping, with a few days rest, will effect a cure. Bruises and treads between hair and hoof, may become serious injuries if neglected; the material thing is to keep them clean, and apply some balsamic tincture, such as myrrh and aloes, friar's balsam, or the like, which may be procured at any chemist's; bruises from blows, kicks, and the like, should be bathed with any kind of repellents, such as cold vinegar, brandy, or goulard, any of which will contribute to disperse the bruised blood. All kinds of green wounds may be cured by the application of the before-mentioned balsams, which defend the wound from the effects of the air, (the air causing wounds to rankle and fester) and where a bandage cannot be applied, will be found preferable to ointments and salves. Old ulcerated wounds, that have horny or proud flesh growing, or become pipey and fistulous, require the aid of the cautery or knife, and here I recommend the assistance of a skilful veterinary surgeon.

Some horses with brittle hoofs, when the roads are hard, will put out a sand-crack; this, if neglected, would become a very serious injury, but if taken in time may be prevented. You will perceive the horn of the hoof to crack or open from the coronet downwards, at first discovering, perhaps, not more than an inch in length, but, if neglected, would soon be all through the horny part of the hoof from top to bottom, and then it would take a length of time to cure, and the horse will all that time be unserviceable. But, in the first instance, as soon as dis-

covered, take a cauterizing-iron and sear the hoof cross ways, at the bottom of the crack, moderately deep; this will prevent the crack from opening further: then, in like manner, sear the top just above the hoof, or what is called hair and hoof; this is to prevent the continuance of the crack as the hoof grows, which would be the case if this method was not taken to prevent it: then melt some Burgundy pitch, and fill up the crack, with the blade of a knife, dressing the seared places, to prevent the dirt and gravel getting in: let the horse rest a day or two, and then you may work him moderately.

Grooms in general take upon themselves to bleed and physic at their own discretion; it is, therefore, necessary to assign some reason, and to shew when and for what purpose such methods are to be pursued; it is best to pursue such methods as preclude the necessity of either, for, with proper feeding, exercise, and grooming, there will seldom be occasion for physic; but sloth or idleness is the parent of disease, and thus it happens with horses, when they are well fed, and have no work—the vessels get filled and overcharged, the economy of the whole system is obstructed, and cannot perform their several functions; the stomach cannot digest its food; the blood-vessels get too full, and have not a free circulation; the lungs are oppressed, and have not free expansion, and, if timely relief is not given, a catalogue of disorders must ensue, for nature will discharge or unburthen herself some way or other. When any symptoms of approaching illness or disorder appear, which may discover itself in various ways, such as refusing his food, languor and dullness, heaviness of the eyes, heat in the mouth, swelling of the legs, itchings, breakings out, &c. it will in general be proper to bleed, as a check, or an arrest, to the advancing malady.

You now compare symptoms and circumstances together, to account for, if possible, the cause of the complaint; if the horse has been well kept, consequently full of flesh, and no work, (for I do not call walking a horse about to stretch his limbs, which lazy grooms will do, and are afraid of sweating them because of the trouble of cleaning them, sufficient to keep a horse in health,) you may reasonably conclude the vessels are overcharged, and evacuations must relieve them; in this case, going through a course of three doses of physic will prevent the threatened or

approaching disease, and restore the horse to health and vigour.

It may so happen that a horse over-fed, and too little worked, may not discover any symptoms of ill after a day's riding or work, as some would call it, and from that circumstance you might not attribute it to the want of exercise, but in this you may deceive yourself, for the malady might be in the horse before the work, and the unusual exertion might cause the discovery sooner than otherwise it would; the like remedy, therefore, is to be pursued.

If the horse has been in regular work or exercise, young and tender constitutions will sicken at unusual exertion, which is termed taking too much out of them; in this case, the loss of a little blood, with a day's rest, will restore them. But sometimes taking too much, and at the same time when the horse is very hot, suffering him to cool too fast, will give him cold and cause a fever; in this case I bleed more copiously—give him plenty of diluting water, with a handful of oatmeal stirred in it, or boiled gruel, letting it stand till it is cold; if he will eat, mashes will be proper for him, as more light of digestion, and keeping the body open; a mild dose of physic may be given for this purpose; but, if you notice at the first, that the horse does not dung or empty himself as usual, (for, as you may observe, a horse in health will empty himself several times a day, as you scarcely go to stable but you have dung to remove from behind him,) in this case the horse should have immediate relief, by raking, and the application of a glyster; any sort of liquor that can be conveniently had, will answer the purpose to soften the hardened excrements, such as warm liquor, gruel, with a bit of lard in it, or the like, and be sure not to administer it too hot; but first let a lad, or any person with a small arm, rake or remove the hardened excrement lodged in the fundament, by larding the hand and arm, and introducing it up the anus; the hardened excrement may be felt, and by little and little taken away, and then the injectment of the glyster will not be impeded; the administering of a glyster, in the first instance, will very often effect a cure, and the horse will be fit for work in a few days. Should the fever continue without abatement, after the ducts are open, in the first instance letting blood and opening of the body, keeping the horse clothed, to prevent cold and promote perspiration, if nature is in-

clined to throw it off that way, and frequent leading in the air, when it is mild and salutary, (but not if cold or piercing, such as would obstruct perspiration, or check the operation of physic,) will, in general, effect a cure; should the fever continue violent, I administer James's powder, and I believe it to be as efficacious as any fever-drinks or powders that can be given: yet, after all, nature does the work, for this is only working with, and assisting her. The obstruction of nature causes disease, the continuance of thwarting and obstructing her will occasion death: if nature is sufficiently powerful to operate, she will of herself effect the cure in in time; but if the disorder is too powerful for nature, she must be assisted, or the horse will die. Assisting nature, therefore, effects or facilitates the cure, and should be always attended to, so that your remedies may second and assist her operations.

When horses take a violent cold, attended with a cough and the like, many will be nursing them in the stable, not letting a breath of wholesome air blow on them, and feeding with warm mashes, giving them comfortable drinks, and cordial or pectoral balls. I must confess I have done the same, but am of opinion it never forwarded the cure. When nature effects the cure, whatever may have been the means applied, it is natural to suppose they effected or restored health, when it is possible they might rather have impeded than assisted in her operations; and this, I believe, is frequently the case in colds. When a horse takes cold, I perceive him to be affected exactly in like manner as myself when I have a cold on me; the offended or obstructed matter seeks to discharge itself by some means or other; sometimes a slight external cold, which may only occasion a stiffness or soreness in the part it was taken, nature throws it off by exercise, perhaps with sweating it through the pores, or through ducts or channels imperceptible to us; sometimes it flies inwards, and affects the bowels, which may cause violent inflammation and fever; at another to the lungs, which brings on the cough; mostly to the head, occasioning a running or discharge at the nose, and sometimes with eruptions and breakings out through the skin. Now, as I would treat myself under such circumstances, so I treat my horse. If it is slight, I keep myself warm, take air and exercise, and leave nature to herself, who, in slight cases, will do better without your

assistance than with it; but if the attack is violent, I am perhaps more kind to my horse than myself, for I endeavour at a speedy cure for him, without consulting his liking, (whereas I have such an aversion to bleeding and physicing myself, that I defer it till I perceive it cannot be done without,) and then never apply to physician or apothecary, but with an emetic or cathartic set the doors open, and let the enemy escape as quick as possible. A horse cannot easily be made to vomit, and therefore it is never attempted by me; but bleeding, purging, staling, sweating, and rowelling, are the usual channels that disease retires by, when skill or medicine attempts to dislodge her. Comfortable drinks and cordials I never administer, not that I think they do injury where the bowels are not attacked with inflammation and fever, but because I think they do no more good than my eating a spiced gingerbread nut, which I should never take to cure a cold, though I am fond of them, yet, because I like them, I may be induced to eat them, and say they are exceeding good things to warm the stomach, and keep the wind out on a cold morning, thereby prevent taking cold; but, when the malady has got deep hold of me or my horse, I don't resort to them for a cure.

In the first attack of a cold, warm clothing will assist nature in any of her operations; if no fever attends the cold, moderate exercise in the clear air, such as will warm and keep the blood in free circulation, without heating him, will be far better than standing in the stable breathing a confined air, which is hurtful to the lungs, and increases the cough; should the cough be bad, and the breath short and oppressed, take about two quarts of blood away, and it will greatly relieve both, and give a gentle dose of physic; let the chill be taken off his water, but if he will drink gruel, it will be better for him; regard should be paid to keep the horse in the dry, and care that he does not take fresh cold: thus, with warm clothing, air, and gentle exercise, with a dose or two of physic, will a cold be got rid of sooner than with stable-nursing, mashes, and cordial-balls.

Should a fever attend the cold, the horse will be off his feed, become languid and weak, and consequently cannot be exercised, otherwise than being led out for the air in the mild and clearest part of the day; but in other respects the like methods may be pursued; bleeding and physicing are the likeliest means of abating

the fever, and dislodging obstructed matter, which is the cause of it.

It gives me no concern or uneasiness when the horse is off his feed, and cannot be brought to eat; this is the natural consequence of fevers, and till the fever is abated, it is best for him not to eat, as food would increase the disorder. If he will drink plentifully of gruel that has been well boiled, and made moderately thin for him to drink, he will take no harm by not eating. When the horse is led out for air, let the stable be cleaned and aired as much as possible, for the very breath of the horse, in a violent fever, is sufficient to contaminate the confined air, and fresh wholesome air will greatly contribute to the recovery of the horse.

When the above methods have been taken in time, they generally effect a cure; but if the fever is very violent, further means may be necessary—sweating and rowelling are resorted to, but, as I observed in the first instance, James's powders will be equal to any sweating that can be given; and as to rowelling, it is disagreeable to most people, and therefore is generally the last thing resorted to, and for which reason I think it is not practised one quarter so much as it was formerly. It is mostly necessary, when there is a violent flux of humours flying about the horse, occasioned by a long continuance of foul and bad feeding, whereby the whole mass of blood is impoverished, and is in a more or less corrupted state; these aqueducts may then be opened to draw away the foul matter from the blood, and in time will effect a complete change of the system.

When the above description of horses fall into people's hands, they occasion a deal of trouble and perplexity to get them to rights, and many are not worth the trouble when you have done all you can; we frequently find a subject like this in a young horse, that probably was got from a good stock, but bred on a bad soil. Some people may suppose, that if the horse does not work, it matters not what he eats, so that he finds something to eat and fill his skin with; horses that are turned out to shift for themselves in various kinds of wastes, that afford no good pasturage, must eat such as they can find, and if the quality is bad and improper, the constitution must be weakened and injured thereby; for it is evident that every animal is materially affected by the food that he eats; even the butter of one dairy is found to be far preferable to a

contiguous one, owing only to the difference of the pasturage; no wonder, then, if a horse which has subsisted for years in swamps and wilds and wastes, eating nothing but faint, foggy, and deleterious food, till he is thought fit to be made up for market, should, when he comes to stand in a stable, and do a little work, exhibit a weak debilitated state of body, that is incapable of work, and the legs swell and fly to pieces, as they term it, if he stands still.

When a person unfortunately has a horse of this description, (for it is only a few that are capable of judging of the constitution of the horse by external appearances, and these horses frequently show good shape, good action, and spirit that recommend them to a purchaser,) he soon discovers a necessity of putting him in condition, and this I find has often baffled the endeavours of the most skilful. As soon, therefore, as the legs begin to swell, and get round, the horse is pronounced to be very foul and full of humours, consequently he must have physic. Physic is administered, and while the physic is in operation, the legs become fine, and the virtue of physic is highly extolled from such favourable appearances. The physic having done working, in a day or two the legs get round again, and consequently another dose of physic is given, which brings the legs fine, while the physic is in operation, and still great dependance is put on the efficacy of the physic; but as before, so again, no sooner has the physic gone through the horse, than the legs again swell; nevertheless, a third dose must be given, which, terminating with no better success than the other, a short respite is taken to observe if the legs will gradually become fine after such a course of cleansing; but if extraordinary care is not taken, they soon show evident signs of being worse, and then a consideration takes place what is further to be done: sometimes a repetition of the physic is pursued; at others, a course of diuretic balls, which in general I have observed to be attended with no better success than the physic; leaving off, therefore, apparently no better than they began, they of necessity now take to the means that should have been pursued from the first, that of using every method of preventing the legs from swelling, for otherwise the horse's heels will break out in chaps and sores, discharging a thin offensive ichor, and, if neglected, would soon spread up to the houghs, and become what is called the grease. The

above description and process, I think, will be acknowledged to be correct by those who are conversant with horses and the practice of grooms.

I have now to give my opinion of the cause and the method I think most likely to cure.

I attribute the legs to swell from one or other of the following causes:—

First, from over fatigue or labour; in which case I have recommended warm fomentations to draw out the heat and inflammation (for warm water certainly cools, as we experience in ourselves); if the feet are swollen and heated with over-walking, rest and moderate exercise, with the fomentation, will restore them in a few days.

Another cause of the legs swelling, is the want of exercise: in this case the blood gets too gross or thick, which causes the grosser parts to lodge in the extreme fine arteries, the most distant or remote from the heart, and this causes swelling and inflammation; this matter must again be put in circulation, and expelled through bleeding, physic, or exercise; if it is taken in the first instance, and no other symptoms appear with it, regular exercise will carry it off, discharging it where it should have been expelled before, through the pores of the skin by gentle perspiration; but if let alone too long, bleeding and physic may be necessary to bring the legs fine, and, as I have mentioned the cause, care should be taken that such cause should no longer exist, for the parts being weakened by the malady, if exercise in moderation is not given, the swellings of the legs may again be expected.

The third and last cause that I can assign for legs swelling, is a corrupt, bad, and impoverished state of the blood, occasioned, as I apprehend, by a long continuance of poor unnutritive food, which has weakened and enfeebled the system. Now, in the other instances, the richness of the blood caused the malady; in this the poverty and feeble state of the blood causes it to loiter in the fine arteries that are enfeebled and remote from the heart, which is the spring of action; and this accounts why physic does not effect or promote the cure in this instance, as in the preceding one, because physic for a time weakens and relaxes the system; and it is the nutritive food, with proper exercise and air, that strengthens, invigorates, and braces the system.

While the physic is in operation, the blood is put in quicker circulation, which

causes the legs to be fine for the time, but, the operation over, the parts are weaker, and less able to dislodge the loitering malady than before; too often repeating the physic I think detrimental, and what now should be aimed at is to use means to prevent the blood from loitering and lodging in these parts, which renders them still weaker and weaker, till the system is renovated by alterative medicines, and clean wholesome food, with regular exercise.

To prevent the legs swelling, walking exercise and air, in the morning and afternoon, and bandages by night, are necessary, for you will find when the horse has stood six or eight hours, his legs begin to swell; for a bandage procure rollers of canvas, or such like stuff, sufficiently long to bind round the pastern and fetlock, up to the houghs, and to prevent the bandage pressing improperly on the tendon or back sinew, lay pledgets of hay-bands, nearly untwisted, and moistened to make them sit comfortable on each side up the sinews, so that the bandage may press those parts which lie in a hollow, and are most likely to swell.

The offending matter lodging in the extremities, renders the parts weak, and the more they are assailed, the weaker and less able they become to perform their functions; the bandage will prevent the humours lodging there by night, and the exercise by day, and the parts will, as the blood gets refined or rectified by proper food and exercise, with alteratives, recover their strength and vigour, and then the bandages are no longer necessary.

If, as it often happens, where horses are not properly attended to, but are let alone till the heels chap and become running sores, (which they will do in any of the instances, if neglected) you must be mindful to wash them with warm water, and keep them very clean, for the humour issuing from these sores is sharp and offensive, and if not kept clean will spread very fast, and occasion such soreness that the horse cannot move his leg at first without extreme pain, because the chap is thereby opened. If the chaps are slight, not attended with much inflammation, and no appearance of small pustules issuing an ichor, and scabbed, I should judge them to be occasioned more by neglect than by disease, in which case, after washing them clean and drying them, you may apply some white drying ointment, which you can procure at any chemist's, and with care and keeping clean, they will soon

be well. But if they have originated from the cause I am now treating on, from a vicious and bad state of the blood, and suffered to get to this length of chaps in the pastern joint, and scabbed about the pastern and fetlock, they must be poulticed, to draw the sharp and offending matter from them, for such cannot be repelled and thrown into the circulation again: after poulticing a few times, washing also, and keeping them clean, you will perceive the pain and anguish to have subsided; you may then let them heal and dry, and use the means as above of preventing the humours from lodging there.

Goulard water, as I have before mentioned, is a great repellent and dryer, and may be used to repel humours from settling till thrown off through other channels, such as bleeding and rowelling, gentle cathartics, and mild diuretics; but the two last I recommend to be mild, and not often repeated, lest, while you correct one part you weaken another.

The best constitutions require much attention to the legs, with the daily rubbings, as I have directed, but extraordinary care is requisite in these constitutions which are termed foul and gummy-legged, such are the appellations given to this description of horses.

Malenders, salenders, and scratches are species of the same disorder, making their appearance in the joints of the hough and knees, and the scratches on the legs; these I attribute entirely to filth and neglect, seldom making their appearance where horses are in any degree looked after: the means prescribed for the gourdy or greasy legs will also cure these, but with all care and cleanliness.

Another occasion for physic will be when you perceive a horse to be infested with worms. Horses, who labour under this complaint, do not always void them in their dung, but may be judged of by appearances, such as the horse not thriving on his food, the coat having a dull appearance and staring, the carcase tucked up and hide-bound, and the horse greedy and ravenous—these are the usual symptoms.

The most certain cure that I know of, (for I have tried various recipes, that are handed down from one groom to another, as certain of destroying them, without effect) is calomel. If, therefore, you apply to your veterinary professor, for mercurial physic, you will have it ready prepared; but should you have plain physic by you, and are so situated that you cannot conveniently

procure it ready prepared, you may get the calomel at any chemist's. I usually give a drachm and a half, and from that to two drachms, for a dose, according to the size or constitution of the horse, and when it is not made up in the physic, I give it in the following manner. I moisten a handful or two of bran in a bowl, and strew the calomel in it, mixing it well together, this I give the horse over-night, and the next morning his physic. I think it necessary to caution you to be careful not to lay the calomel heedlessly about, nor administer it in larger portions than directed, because much mischief, or inevitable death may ensue.

The calomel being given as directed over night, you must be certain that the physic is taken the next morning, and the only difference of ordering your horse is to be careful that he does not take cold, for mercury is very searching and penetrating, and if checked in its proper course, will certainly take a course that is not desirable; additional cloathing to what the horse has been accustomed to, and agreeable to the season or temperature of the air, should be put on; keeping him in the dry, and from any sharp penetrating winds, and letting his water be warm—I don't mean hot, but something under blood warm, for sometimes I call the blood hot; you require the horse to drink plentifully in physic, but the warmer the water, the less he will drink of it; nevertheless, with mercurial physic, don't let it be too cold.

Three doses of mercurial physic will be sufficient.

When horses under the predicament of lameness, so that they cannot work, are likely to be idle for several weeks, feed sparingly, and occasionally give a moderate dose of physic, to prevent consequences arising from idleness; but when in health, exercise precludes the necessity.

Blistering and cauterizing are remedies frequently practised, or at least recommended by grooms; there are circumstances in which they may be necessary, but many times they are advised by the grossest ignorance, and the person thinks himself of no small importance in proposing remedies, as he imagines it shews him to be a great adept in his profession. Farriers, frequently as ignorant as the grooms, find an interest in being on good terms with them, and therefore seldom oppose their opinion; so that if a consultation is held between master, groom, and farrier, two

to one are certain to carry the proposition, and the horse is sometimes needlessly tortured.

The cause of lameness in a horse, where there are no external appearances, is sometimes so difficult to find out, that I have known four persons give as many opinions of the seat of lameness, and perhaps not one of them right. Where the seat of the disease is not to be ascertained, I shall not pretend to prescribe a cure; but it sometimes happens that a horse puts out what is called a curb, becomes sore, and occasions lameness; this taken at first appearance, is removed, and perfectly cured by a blister, but if you let it continue for a while, the substance will increase, and be more troublesome to remove, requiring a stronger blister, or twice blistering; other extraneous substances, at their first appearing, such as splents, (substances growing on the shank bone, which, if small, are not worth notice, but if large, and growing near the back sinew, will be troublesome, and cause lameness) may be removed, or greatly assisted, by blistering. As may, also, if taken at an early period, spavins, and thorough pins, which are hard bony substances forming on the joints of the houghs, &c. any such extraneous hard substances taken in the first instance, may be greatly reduced by blistering.

When horses have for a length of time been accustomed to excessive labour, whether from hunting or road-riding, their sinews and joints will become what is termed bummed, that is, the pastern-joints and sinews will become enlarged and stiff. Exercise or work in moderation, is not only conducive to health, but likewise strengthening and bracing to the whole system; but we find the best things, taken or used to excess, become pernicious and hurtful; without labour, the joints and ligaments get relaxed and weak, which causes the horse frequently to make a drop, and many a good horse on sale has been rejected for a circumstance of this kind, which regular work would have removed: but again, when the labour for a continuance has been excessive, the joints and sinews become more enlarged; then rest, with the ordinary means of grooming, will restore them, but the horse at first going out will appear very stiff, and sometimes lame; turning them out for two or three months, may refresh the legs, and bring them somewhat finer, but still where the sinews have been much oppressed with heavy or long continuance of immoderate work, a weakness will remain,

and blistering will be advisable. Now as the blistering should be previous to the turning out, the judgment is to determine whether there is a necessity for both; if the horse is but little gorged about the legs, and but little stiff at first going out, without any perceptible weakness or lameness, the turning out I should judge would sufficiently restore him; but, on the other hand, you must blister and turn out. I cannot persuade myself that blistering is good, if there is not the necessity for it, though I have known several that make a practice of it, alleging that if it does no good, it does no harm; how far that doctrine may be just, I will not take upon me to determine; but I know it puts the horse to a deal of pain, and without proper care is taken, the horse may be greatly disfigured by it.—See BLISTER.

When horses have been hard worked, turning out is a natural consequence, to refresh their limbs, but they are also turned out when not wanted for present use. The hunter, when the season is over, is turned into good grass to cool his body, and refresh his limbs, which, if he has been regularly hunted the season through, must stand much in need of it; but if only occasionally, and he is wanted for the road, there is no necessity for it. I have known horses to be kept in stable a dozen years, without eating any green food, yet have continued in health and condition; there are some constitutions in horses that will not thrive and look well in the stable for any continuance, but get tucked up, hide-bound, and dead-coated; yet such, in my opinion, are not worth keeping; they will have a tolerable appearance, after a month or six week's grass, which is the best time to dispose of them, for they will soon return to their former state in the stable, with only having moderate work. I would not have it understood that grass is improper for horses; on the contrary it is very good where they can be spared; and pleasure-horses that are only moderately rode, may be kept to grass and worked occasionally, all the summer, giving them corn when they work. It is for appearance and ability to do extraordinary work, if required, that condition is in such request. The horse that runs at grass, and is worked all the summer, is soon got into condition for hunting in the winter, for

his occasional working prevents him getting over-fat and gross with the grass; and without physicing when taking him up, give him dry food, with some good sweats, and he will soon be in wind and condition for hunting.

Turning out in winter to a straw-yard is a custom with those who keep a horse for pleasure in the summer, and have no occasion for him in the winter; they will tell you how beneficial it is for the horse, cooling to the body, and bracing to the limbs; but these arguments do not meet my concurrence. To keep horses in stable is expensive, and where exercise is not convenient to be given, is injurious to the horse; but not so hurtful as to be nearly famished. When a horse has been rode hard all the summer, his legs may become gorged, and require rest to refresh and bring him about, and this may be the only season he can be spared; therefore, under all circumstances, it is more convenient than beneficial for a horse to be turned out in winter.

When it becomes expedient either for the refreshment of the horse's limbs, or the sparing of the owner's pocket, I cannot but recommend that the horse should be prepared for the extraordinary change he is to undergo, by first leaving off his cloaths, then removing him to a cooler stable, leaving off dressing, giving him less, at last no corn, and by degrees to an empty stable or shed to lay under.

When gentlemen have conveniences of their own, to turn horses out in winter, there is no doubt of their being taken care of; in open weather there is much pasturage, and in hard weather an out-house or stable to lay in, with plenty of hay. A horse may be benefitted by a winter's run of this sort, but I am alluding to straw-yards, where they take in all that come, and account they do well by them, if they keep them alive.

Green food in the stable, as a cooler and alterative, is admissible, and highly proper, for some constitutions will not do well without it; dry food for a long continuance not agreeing with them, and no quantity of dry food that you could give would make them thrive, but they will be lank, do all you can.—For further observations on CONDITION, see HUNTER and TRAINING.

## C O N F O R M A T I O N

**CONFORMATION OF THE HORSE, EXTERNAL.** As the powers and qualities of this useful animal are known to depend considerably on his external conformation, it is a point which has long and deeply interested the gentlemen of the turf, and others who have given their attention to the improvement of the breed. Of the few modern writers who have treated the subject scientifically, there is none, perhaps, more worthy of attention than Mr. Lawrence, of Birmingham, who, in his elegant publication, entitled—*An Inquiry into the Structure and Animal Economy of the Horse*, makes the following remarks:—

As deformity, says he, is constituted by a want of harmony in the component parts, it will not be difficult to perceive, that a long head and a short neck, or a short head and a long neck, cannot be esteemed handsome.

The neck should proceed in a line from the top of the head, forming a regular progressive curve to the withers. The trachea, or windpipe, should be large in diameter, and somewhat detached from the fleshy part of the neck. The size of its diameter has a considerable influence in respiration. Large windpipes are peculiar to blood-horses, whence, probably, they are better winded than all others. The chief beauty of the forehead depends on the union of the neck with the shoulders. The neck should issue high, and nearly in a line with the withers, and its lower part should enter the chest high, and above the point of the shoulders: the opposite conformation to this produces what is termed an ewe-neck, which can never be esteemed handsome.

The shoulders constitute the centre of motion in the fore part of the body; and the extent and elasticity of that motion will depend chiefly on the position of the shoulder-blades. The connection of the shoulder-blades with the body is established by muscles only, independently of any joint whatever. It is by the alternate contraction and extension of these different muscles that motion is produced, and it is by their united elasticity that the shock is broken when in action.

This would not have been the case, had the shoulder terminated in a fixed joint. The truth of this remark may be ascertained by riding alternately on the withers and the croup, and comparing the difference of their respective motions.

As it is the office of the hinder quarters to propel the body forwards, it is necessary that they should be closely united with the body by means of joints. But, on the other hand, as the fore quarters are chiefly employed in sustaining the equilibrium of the machine, the concussion which must have been produced if they had been united to the body by joints, would have been considerably greater than what is produced by their being attached by muscles only. In describing the action of the shoulder, it will be necessary to consider its position when in a state of immobility.

The scapula, or blade-bone, is placed obliquely from the chest to the withers, and the centre of its action is fixed in the middle of it.

## C O N F O R M A T I O N

In its action, it describes as large a portion of a circle as the extension of its muscles will admit. If this portion of a circle, for instance, be ten degrees, and two different scapulae possess the same degree of extension, the one situated obliquely, the other perpendicularly, it must necessarily follow, that, acting on their respective centres, the one which is oblique must elevate its lower extremity higher than that which is perpendicular, and consequently will increase the projection of every part of the fore-limb. Hence it appears, that an oblique position of the shoulder is most favourable for progression.

The shoulder may want liberty, either by being too fleshy or too lean. In the first instance, it is overloaded; and, in the last, it possesses not muscle sufficient to enable it to perform its functions with strength and celerity.

The muscles of the chest contribute greatly to the motion of the lower part of the shoulder. Hence a strong and moderately full chest is to be preferred to one that is narrow and meagre. It will probably be urged, that horses are sometimes possessed of great speed whose fore-hands in nowise agree with this description; but such horses are generally endowed with particular powers in their hinder quarters. The fore quarters are merely passive, and extend themselves to receive the weight of the body; and, if they are sufficiently strong for that purpose, the animal may certainly move with considerable velocity; but thence it is not to be inferred that a greater velocity might not be produced, if both the fore and hinder quarters were alike perfect in their conformation.

The fore legs will next come under consideration, on the good structure of which the safety and ease of the pace of the animal will chiefly depend.

A horse whose legs are twisted, or improperly placed too far under his body, may possess great speed; but that his action must be imperfect, the following reasons will sufficiently demonstrate:

If the foot turns either inwards or outwards, it cannot alight flat on the ground, in which case the position can never be firm and steady; because the pressure will be partial on either the inward or outward quarter of the foot. If the leg is not perfectly straight from the shoulder to the foot, its action cannot be true, nor the centre of gravity so readily found, as by one that is even and uniform in all its parts. If the elbow incline inwards close to the ribs, the leg must be thrown sideways when in action, which will remove the foot too far from the centre of gravity, and produce a lateral rolling motion, very unpleasant to the rider. Again, if the legs incline too much under the body, they will be overloaded, and the freedom of their action will be reduced in proportion as they are oppressed.

The fore legs, to be perfect, should, in a front view, be widest at the chest, gradually approaching each other downwards towards the foot, and descending in a perpendicular direction to the ground.

The upper part of the fore-leg, next the shoulder, should be broad and muscular.

## C O N F O R M A T I O N

The power of elevating the knee, and throwing the leg forwards, depends much on the size of the muscles in this part.

The knee, in a front view, should be broad, flat, and square; the lower part of the limb, between the knee and the fetlock, should be short, flat, and wide in a lateral view. The tendons should be distinct, firm, and detached from the bone. The fetlock should correspond in proportion with the rest of the leg, neither too upright nor too sloping. If it is too long, its ability of sustaining the weight of the body will be diminished; and, if it is too short, it will be liable to knuckle over. Short pasterns are generally attended with contracted feet, the weight of the body not being thrown so much on the heel as is the case with long pasterns.

The general proportion of the limb is constituted by two equal divisions, viz. from the elbow to the knee, and from the knee to the ground.

The length of the fore leg should correspond with that of the hind leg; that is to say, the elbow should describe a horizontal line with the stifle, otherwise the harmony of motion is lost; as is the case in a carriage, where the fore wheels are of a smaller diameter than the hinder wheels, on which account they are obliged to perform three revolutions to two of the latter.

**BODY.** The common appellation of this part, amongst horsemen, is the carcase. Thus a horse is said to be long or short in the carcase. A horse which is short in the carcase is usually *ribbed home*, as it is termed, that is to say, there exists but small space between the last rib and the hip-bone. This conformation is justly esteemed excellent. A horse thus formed is generally short in the back and wide in his loins, and better adapted to carry weight and bear fatigue than a horse of a different form.

Horses of this description, however, are commonly supposed to be deficient in speed, from the idea that they have not sufficient length. But when it is considered that the trunk or body has no motion of itself, but is entirely acted upon by the quarters and extremities of the animal, it is manifest that the length should exist in these parts, and not in the body. In proof of this, two horses may be found exactly of the same length from the point of the shoulder, at the chest, to the point of the buttock, and yet one horse shall be long in the carcase, and the other short.

The fore part of the carcase contains the heart and lungs, and should therefore be sufficiently capacious to admit of a free action in those viscera. Horses with flat ribs experience a greater pressure from the atmosphere in their breathing than those do who have their ribs more arched; consequently, they are not so well adapted for respiration. The posterior part of the carcase contains the stomach and intestines, and is generally round and capacious in horses of a strong constitution. The back should sink in a small degree behind the withers, and proceed in a straight line to the end of the loins, and thence fall gradually to the tail. A hollow back renders the motion of the animal easier to the rider, but certainly cannot be so

## C O N F O R M A T I O N

strong as one that is straight. A roach or hog back constantly throws the saddle forwards on the shoulders—a circumstance productive of great inconvenience to the rider.

The loins should be wide, and the hips low. The distance of the point of the buttock from the hip should be considerable. The lower part of the buttocks, in a posterior point of view, should be wider than the hips. The tail should issue from the croup in a regular progressive curve, and not appear as if it was stuck into the rump.

The hinder quarters may properly be considered as the main spring of the whole machine. This is clearly demonstrated by the superior size of the muscles, and the angular position of the thigh bones.

It has generally been the custom to attribute the source of motion principally to the fore quarters, under the idea, that if the fore quarters could move well and with speed, the hinder quarters must naturally follow. The fallacy of this doctrine may be easily exposed. In the action of a self-moving body, the posterior part generally constitutes the fixed point from whence the motion takes its origin. Thus, if the horse leans forwards, the centre of gravity ceases to be supported, and he is obliged to advance one of his fore legs in order to recover the equilibrium. Again, if the chief source of motion exist in the fore quarters, whence does it arise that many good fore-quartered horses are bad leapers? The reason is obvious: from weakness in their hinder quarters; for the principal strength of a horse lies in the muscles of his thighs. Therefore, a horse may rise well at a leap, and clear it with his fore legs, but cannot bring his hinder legs over, unless the muscles of his thighs are sufficiently powerful.

It may be urged, that leaping differs from galloping; but galloping is, in reality, constituted by reiterated leaps on a plain surface. Hence the necessity of a good conformation in the hinder quarters.

Of this doctrine Mr. Lawrence adduces a strong instance in the celebrated horse, Eclipse, unquestionably the most speedy horse of his day; for it seems his fore quarters were very ill formed, and his shoulder low; but his hinder quarters were furnished with strong muscles.

“Of symmetry, or shape, (Osmer observes,) if it should be asked, why the get of the Godolphin Arabian were superior to most horses of their time, I answer, because he had great power and symmetry of parts (head excepted), and a propriety of length greatly superior to all other horses of the same diameter of carcase, that have been lately seen in this kingdom. This I assert, not on my own judgment alone, but on the united opinions of those who, I believe, understand horses much better than I pretend to do: and it is very probable, this horse, if he had not been confined to particular persons' mares, might have begot better racers than any he did. On the contrary, I have heard it urged in regard to his blood, that he was a very mean horse in figure, and that he was kept as a teaser to Hobgoblin, some years before he covered, when he got Lath out of Roxana, in 1731. What does all this prove? I think nothing more, than that

## C O N F O R M A T I O N

his first owner did not understand rightly this kind of east-country horse, and that different men differ in their opinions of the horse's conformation.

It has been said, that the get of the Godolphin Arabian had better wind than other horses, and that this perfection of the wind was in the blood. But, when we consider any horse thus mechanically made, whose levers acquire more purchase, and whose powers are stronger, than those of his adversaries, such a horse will be enabled, by this superiority of mechanism, to act with greater facility; and, therefore, it is no wonder that the organs of respiration (if not confined or straitened more than his adversaries') should be less fatigued.

The question, then, is, whether this excellence of horses is in the blood, or in the mechanism and proportion of the horse? Whoever is a stickler for blood, let him take two brothers of any sort or kind, and breed one up in plenty, the other upon a barren heath; I fancy he will find, that a different form and mechanism of the body will be acquired to the two brothers by the difference of their living, and that the blood of him brought up on the barren heath will not be able to contend in racing with the mechanism of the other which has been brought up in a land of plenty. Now, if this difference of shape will make a difference in the performance of the animal, it will be just the same thing in its consequences, whether this imperfection of shape be produced by scarcity of food, or entailed by the laws of nature; if so, does it signify whether the colt be got by Arab, Turk, or Barb, or what kind of blood his dam be of? Indeed, where shall we find one certain proof of the efficacy of blood, in any horse produced in any age or any country, independent of the laws of mechanics?

If these things are so, have not we and our forefathers been hoodwinked all our lives by the prevalence of a ridiculous custom, and mistaken system, whereas, by consulting our own reason and understanding, this mist of error would have fled before it! If this mechanical power was considered as it ought to be, it would excite a proper emulation among all breeders; and, when the excellence in the breed of horses was found to be the effect of judgment, and not of chance, there would be more merit as well as more pleasure, in having bred a superior horse or horses. Add to this, mankind, by applying their attention to this mechanism of animals, would improve their judgment in the laws of nature; and it would not only produce a much better breed of racers than any we have yet seen, but the good of it would extend to all sorts of horses throughout the kingdom, of what kind soever, in a few generations.

Finally, when speaking of the higher class of horses, instead of the phrase *high-bred*, well-bred should be substituted; and this not even then be understood to mean any thing more than that they are descended from a race of horses, whose actions have established their goodness: preferring the mechanical powers of a horse, to all simple opinions concerning blood, which is, in reality, no more than a vain chimera, when taken alone for argument.

*Terms generally made use of to denote the parts of a horse.*

1. The vertebræ of the neck.
2. The sternum, or breast.
3. The scapula, or shoulder blade.
4. The humerus, or bone of the arms.
5. The radius.
6. The ulna.
7. That part of it called the olecranon, or elbow.
8. The ribs; eight of which are called superior ribs, connected with the sternum, the others are called the false ribs.
9. The bones of the carpus.
10. The metacarpel bone.
11. The great pastern.
12. The little pastern, or coronary bone.
13. The coffin bone.
14. Vertebræ of the back.
15. The six vertebræ of the loins—there are eighteen bones in the tail.
16. The os innominatum, or bason bone.
17. The femur, or thigh bone.
18. The patellæ.
19. The tibiæ, or greater bone of the leg.
20. The fibulæ, or small bone of the leg.
21. The bones in the hock.
22. The metatarsal bone.
23. The great pastern and the lesser pasterns.
24. The coffin bone.

*FAMILIAR TERMS.*

- a. The crest. When horses are out of condition, this part wastes, and they are said to be crest-fallen.
- b. Withers.
- c. Throat.
- d. Shoulder points.
- e. Arm.
- f. Knee.
- g. Fetlock joint.
- h. The pastern joint.
- i. Foot.
- ii. The coronet.
- k. Body.
- l. Quarters—over the hips is called the croup.
- m. The dock.
- n. Sheath.
- o. Hock.
- x. Where curbs come.
- p. Shank bone.
- q. Fetlock joint.
- r. Pastern.
- s. Foot.
- t. Thigh.

*THE FOOT.*

1. The toes of the foot.
2. The horn of the foot.
3. The sole.
4. The frog.
5. The heels.

*THE PROPORTIONS OF A HORSE.*

AA. The line which divides the body from the legs, giving the proportion of both.  
 B C. The lines which divide the body from the fore and hind quarters, giving their respective proportions.

\* \* \* Though horses vary very much in their proportions the following measurements, which were taken by Mr. G. H. Laporte, from a horse that was considered proportionable, may serve as a guide: the measurement given is superficial, supposing the animal flat, which gives the principal points.

	FT.	IN.		FT.	IN.
The length of a head generally	1	10	Across the arm . . . . .	0	6

CONSUMPTION. Gibson asserts, subject to consumptions, being washy, that fiery hot horses are the most and of a hectic disposition. They for the

most part lose their flesh, and look faint and jaded; a hectic fever often attends, so that they feel all over hot, though not to such a degree as in inflammatory and other fevers: but these symptoms generally wear off with two or three days' rest, and their appetite to food will also return, but they are apt to relapse as soon as they are put upon fresh exercise; and though they are never so much indulged with rest and food, they seldom carry much flesh.

When a consumption proceeds from any defect in the lungs or principal viscera, the eyes look dull and a little moist, the ears and feet are for the most part hot. There is commonly a sharp cough by fits, and frequently with a groaning, and the horse sneezes very much, has an uneasiness and quick motion in the flanks, often runs at the nose, and some consumptive horses throw out a yellowish curdled matter. They have but little appetite to food, especially to hay, but will eat their corn, and are for the most part hot after it. Sometimes these symptoms abate, and give hopes of recovery; but the least over-exercise, or error in feeding, brings them to their former state. Some look sleek and smooth, though their flesh be wasting; others have rough and staring coats, and appear also to be surfeited: but these different appearances are usually owing to the different causes from whence the distemper originates.

When a horse that has any of the above-mentioned symptoms retains a tolerable appetite to food, holds out a long while without any great abatement of his strength, or loss of flesh, it is always a good sign: on the contrary, when he continues losing his flesh and vigour, it is a sign of decay, even though he retains a tolerable appetite; and any such horse will seldom recover. When a yellowish or curdled discharge runs from the nose, the animal generally dies; but if the matter be white and well digested, and at times abates, or changes to a clear water, it is a promising sign, especially if the horse be young: but, even where the best symptoms appear, consumptions of all kinds are dangerous and uncertain, and every accident or error exposes a consumptive horse to relapses; because his complaint is often owing to natural weakness.

As to the cure of consumptions, one of the principal things is bleeding, which should be small in quantity, but often repeated, especially in the beginning, be-

fore the horse loses too much of his flesh. This sometimes abates the hectic fever which usually attends consumption, and is a relief to the lungs. A pint at once, or a pint and a half from some horses, is sufficient; and this may be repeated as often as they appear to be more than ordinarily oppressed in breathing. All those things that are proper in colds are profitable here also. Gibson recommends the following balls, which, he says, will do service, if the horse be young.

Take of Conserve of red roses, 1 oz.

Lucatellus's balsam, half an oz.

Spermaceti in powder, 2 drs.

Sal prunella, 2 drs.

Balsam of sulphur anisated, sufficient to make it into a ball; to be rolled in liquorice powder or wheat flour.

These balls may be given one every morning for a week; and if they be found to do service, may be continued during pleasure, till the horse recovers his usual vigour, and begins to gather strength.—A quart of the decoction of bran or of linseed may also be administered after each ball, made warm, dissolving in it an ounce of gum arabic, or gum tragacanth; but if the horse scours, or runs at his nose, so as to induce weakness, the following infusion may be used:

Take of Ground-ivy, a handful.

Horehound, a handful.

Red rose leaves, half a handful.

Linseed, half an oz.

Juice of liquorice, half an oz.

Gum tragacanth, an oz.

Infuse these in a quart of boiling water, letting the infusion stand covered till cold.

To be made milk warm, and given every morning after the ball, with the usual precautions; that is, fasting two hours before and two hours after, allowing him not above a quartern of scalded bran; for, when scalded bran is often given, and in great quantities, he says, it hurts the horse by relaxing too much, and is greatly injurious in all habitual weaknesses. His oats should be the hardest and sweetest that can be got, and his feeds also small, that he may not be cloyed. His hay should also be the finest, and the dust well shaken out of it, and given in small portions, that he may digest it easily. But nothing contributes more to the cure of a consumption than air and exercise, though any excess in the latter is dangerous; and therefore a weak consumptive horse should only be led, or ridden by a person of a light weight; and, if short-breathed, should

only be walked. He should be continued in the air as much as possible, upon some dry common, or other place where the air is good, which is the most likely way to bring him to his stomach, and consequently to his strength; and, if he mends by this management, there may be some hopes of his recovery, provided he be young: but if he be full-aged or old, or if he continues still weak and faint, runs a viscid gleet from his nose, has a fullness of the glands under his jaws, coughs much and wastes in his flesh, and grows weak, with a stinking breath, it will not be worth while to bestow any labour or expense to save him.

Some young horses continue in this consumptive way for seven or eight months, with a great deal of care and good nursing, and, at some intervals, give the owners hopes of a recovery, but at last die emaciated. Others go off in a much shorter time, and not so much debilitated; and some recover that have had a running at the nose for two or three years together; but then this running has abated very much at times, the matter was always white, and, when that ceased at any time, there was generally a flow of clear or whitish water. Such horses will retain their appetite, and not lose their flesh, but go through their business tolerably well, with good usage; though, if they are put to it a little more than ordinary, they will be the worse for it: and persons who have had much practice this way may observe, that these horses seldom recover perfectly till they are about seven or eight years old; then their complaints go off, and some of them grow hardy and useful.

An **ATROPHY** is another kind of consumption to which horses are sometimes subject; where a horse has little or no cough, no running at the nose, nor scarce any symptoms of a hectic fever, eats his meat tolerably well, and yet continually wastes in his flesh, and grows at last very hide-bound. This is a dangerous malady, and, for the most part, proceeds from a surfeit or hard usage, and sometimes ends in the farcy or glanders. Some gentlemen have been at great pains and expense in hopes of curing favourite horses that have been thus declining, though without effect; for, in many such cases, the glands of the mesentery, and other lymphatic glands, are very much enlarged; and as, when these are grown hard and schirrous, they hinder the chyle and lymph from mixing with the blood, the horse loses his proper nourishment, and

therefore nothing can produce a cure in this case but what is of sufficient efficacy to remove the obstructions of the glands; and this must be attempted speedily, or not at all.

Therefore, before a horse is too far wasted, give him two drachms of calomel in any of the common horse-balls, in the morning before meat or water, letting him fast two or three hours after it. His food must be scalded bran and the sweetest hay, while he is under this course; he must have no cold water, nor be exposed to wet. The day after this dose of calomel, let him have a mild purging ball; for a horse in this state will not well bear those that are strong.

**CONVULSIONS**, those involuntary and alternate contractions of the fibres or muscles of an animal which arise through the medium of the nerves. Gibson, referring all convulsive affections to the brain, includes, in his chapter on that subject, tetanus, worms, ulcerations of the viscera, costiveness, &c.; an arrangement by no means according with modern theories.

When convulsions attack only particular parts, they are often attended with some kind of paralysis at the same time, by which means the affected parts are alternately convulsed and relaxed. A permanent convulsion, or unnatural contraction of particular muscles, is called a spasm, or cramp. These partial convulsions may attack almost any part of the body of an animal, and are not unfrequently symptomatic in fevers, worms, &c. The involuntary startings of the tendons in acute diseases are all of them convulsive disorders. Convulsions, even when most generally extended, differ from epilepsy in not being attended with any abolition of sense, and in not being followed by the same torpid state.

Convulsions, not only of particular parts, but also over the whole body, often take place from causes not very evident.— Sometimes, in young animals, they seem to depend merely on the irritability of the nervous system, which is strongly affected by slight causes. Convulsions, however, often take their rise from wounds, irritations of the stomach and intestines by worms, poisons, violent cathartics, &c.

**COOLERS** are such medicines as, by their attenuating property, tend to divest the blood of its viscosity, and to counteract threatened inflammation. They are always useful in plethoric appearances: when a horse is evidently overloaded, and

above himself in flesh, when the legs are full, round, and all the vessels are palpably distended, cooling medicines, and gentle exercise, are the direct means of obtaining relief. Bleeding should take the lead, followed by a course of diuretics, mild or strong, according to the size and strength of the subject. Nitre, incorporated with half its weight of gum arabic in powder, and dissolved in the water, is an excellent article of this description.

**COPPER CAP, THE.** Since the application of percussion powder to the discharge of the fowling-piece, various modes have been tried; but the copper cap is preferable to every other; and the nipples, or touch-holes, upon which the caps are placed, should be screwed into the barrel on the upper part of the breech, in a sort of sloping direction.

**CORNS**, as they are called, would be much more properly denominated bruises, and are of infinite trouble to those who implicitly submit to the Quixotic schemes and manual dexterity of the smith; who, with a *secundum artem* expedition, instantly renders the remedy worse than the disease. As his principal province is the art of cutting, he has no sooner the drawing-knife in his hand, than he is at "the bottom:" his great object is the destruction of parts; and he piques himself upon doing more mischief in two minutes, than nature can restore in three months. Impressed with no idea but instrumental extirpation, he proceeds to excavate the sole of the foot, till, having reached the membrane, a protrusion ensues, and leaves him a happy opening for the bar-shoe, hot-stopping, a daily dressing, and the collateral considerations which constitute a sum total by no means necessary.

Corns mostly originate in the shoe having swerved a little from its proper seat upon the wall or crust of the hoof, and becoming, as it were, indented upon the outer sole, occasions a bruise, appearing to have ramifications of extravasated fluid in very fine and oblique directions: the shoe being permitted to press upon this part, (become irritable by the injury it has sustained) produces pain and impediment to action. Upon the discovery that such has taken place, the remedy is as simple as the cause by which it was occasioned. The shoe being carefully removed, take from the surface of what is miscalled a corn, just enough to leave the part free from pressure by the shoe; moisten once externally with a few drops of oil of vitriol, or simple aqua fortis; and

the operative smith, farrier, or veterinary surgeon, will not find a plea for the devastation he is generally so ready to promote.

**CORDIALS.** Medicines which act by stimulating the stomach, and quickening the circulation of the blood. Of this description are the whole class of aromatic substances, volatile and ardent spirits, &c. which, given to excess, produce secondary debility, and exhaust the animal powers, after having caused an inordinate exertion of them.

Mr. Clark very properly reprobates their indiscriminate use in veterinary practice. He says, when horses fall sick, it matters not with some what may be their complaint: it is too common to give them such things as many people esteem cordial or comfortable things to themselves; these are ardent spirits, a little diluted, or wine, ale, &c. either alone, or heated and mixed with different kinds of spices. Wine or ale may indeed be given, in very small quantity, to a horse that is in health, when tired or fatigued on a journey, or in consequence of very hard labour; but they are by no means proper to be given in any quantity to a horse that is sick, more especially ardent spirits, as neither the stomach nor the head of a horse, even in health, can bear much of these liquors at any time. On the contrary, he soon turns giddy, and loses the use of his hind quarters, during a fit of intoxication; and, when given to a horse that is sick, they may be expected to add fuel to the disease, unless his malady be such as really to demand the internal exhibition of stimulants for its cure; but these distinctions are seldom attended to.

**CORIANDER**, the name of a horse who acquired much celebrity by his performances upon the turf for six years in succession. He was bred by Mr. Dawson, and was got by Pot8o's out of Lavender, who was got by Herod; her dam by Snap, out of Sweet William's dam by Cade.—He was foaled in 1786. In 1789, when three years old, he beat Jericho, over the Ditch-in, for 200 guineas, and Sir W. Aston's Marcia, two year old course, 100 guineas. First spring meeting, 1790, he beat Buzzard, 7st. each, 100 guineas.—Second spring meeting he beat him again for the same sum. He beat Egbert and Isabel, a sweepstakes of 100 guineas each; and Shovel, Glaucus, Alexander, and Sir Thomas, a sweepstakes of 50 guineas each; Baronet, Nimble, Egbert, and Sir Pepper, paying forfeit. He walked over for the

King's hundred at Ipswich; and beat Lord Barrymore's Pellegrine the two middle miles of the Beacon for 200 guineas.

In 1791 he won a subscription purse, beating Spear, Isabel, Ruffian, Black Deuce, and Mouse. He also won the plate at Swaffham, beating Isabel and the Sister to Imperator; and the next day won the other plate, beating Clayhall.—At Newmarket, in October, he beat Highlander, Serpent, Halkin, and Espersykes; after which, over the Ditch-in, he beat Escape, Skylark, and Pipator.

When rising six years old, he received forfeit from Sir C. Turner's Weathercock, and won the King's plate at Guildford, beating Enchanter and Braggadocio; also the King's plate at Nottingham, beating Young Cicero.

In 1793 he won the aged plate at Newmarket, beating Dragon, Halbert, and Halkin. He won the King's plate also, beating the Duke of Bedford's Skyscraper. Second spring meeting, he won the Jockey Club plate, beating Skyscraper, Bustler, Cardock, and Pipator; and on the same day won the weight for aged plate, beating Hubby, Volanté, and Eager. In the same meeting he beat Buzzard, the Beacon Course, for 200 guineas.

In 1794, when aged, he won the whip and 200 guineas, beating Creeper, 10st. each, over the Beacon. He won £50 at Chelmsford, beating Sweeper and Portland; likewise £50 at Northampton, beating Triumvirate, and a son of Faggergill. At Newmarket, in October, he won the aged plate, beating Quetlavaca, Exciseman, and Halkin; and in the same week he beat Lord Egremont's Gohanna (giving him 24lb.) and Lord Strathmore's Hermes. In the second October meeting, being the last time of his running, he won a subscription purse, (paying 50 guineas entrance,) beating Lord Grosvenor's Exciseman, and Lord Sackville's Silver.—This extraordinary horse was one of the very few who stood so many years' training, and so much severe running, without an accident. He covered afterwards in the north, at seven guineas, and has produced some good runners.

**CORKINGS, or CALKENS.** The indefatigable *Mr. Lafosse* has given his readers a caution against the use of *cramps*, or what we in England term *calkens*, and vulgarly *corkings*; that is to say, turning up the shoe at the point of the heels to prevent slipping on the stones in frosty weather. He says, that "the frog being hereby removed to a great distance from

the ground, the tendon will be inevitably ruptured." But this is true only in part; as, in all minor strains of the tendons which do not amount to absolute disease, these give or relax a little, so as to ease off the concussion that would rupture them. In summer time, I am free to allow, this effect would frequently happen when the ground is dry and hard, and the horse put on his best pace; but then, no one thinks of *calkens* at such a season, whilst, in the winter season, when the ground is usually wet and soft, this cannot happen in a flat shoe, because the calken of the shoe-heels then buries itself in the ground, so that the frog is still admitted to touch the ground and to rest thereon. I therefore conclude it is necessary and proper that all sportsmen who hunt over hilly or slippery countries should have their horse-shoe heels turned up in winter time, especially the hinder ones, for the security of their persons: they may do so, if they choose, without danger of rupturing the tendons, and some would come home less lame with calkens than without them.

**CORNER-TEETH**, are the four teeth at the extremities of each row in both the upper and the lower jaw, situate between the middle teeth and the tushes: the corner teeth in the lower jaw, are those which the horse sheds when four years old off, and rising five; these not spontaneously exfoliating in time to accommodate the pecuniary propensity of the dealer, he possesses the means and the practice of selling a four year old colt for a five year old horse; and this is so constant, that there is with that class nothing dishonest considered in the custom.

**CORONET** is the part surrounding the foot of the horse just above the junction of hair and hoof: the bone from which the name is derived, bears great affinity in form to a ducal coronet, and is situate between the lower part of the fetlock-bone and the coffin, into which it is inserted, jointly supported by the nut-bone behind. Ligamentary twists, or distortions, sustained at the superior junction of the coronary bone, frequently occasion a prominence upon the coronet, which becoming first callous, and then ossified, is termed a ringbone.

**COSTIVENESS**, a morbid retention and hardening of the fæces, common to most animals. In horses it sometimes arises from violent and hard exercise, especially in hot weather. Sometimes costiveness proceeds from a contrary

cause, viz. from standing long at hard meat, without grass or other cleansing diet, and having but little air and exercise, or having their exercise only in spurts and not continued. When costiveness proceeds from either of these causes, it is easily remedied, if taken in time. But there is another kind of costiveness in horses, which is more hard to be removed, viz. that which seems to be natural, or grown into a habit.

In the first case, the cure is obvious, only by giving him an open diet for some time; and, if any thing more is wanting, lenitive and mild purges are the most likely to succeed. In the second, when costiveness proceeds only from want of air and exercise, and a cooling lax diet, it is no less easily remedied with proper lenitives; as a single drachm of aloes, frequently repeated, according to its effects. Gibson recommends Glauber's salts with lenitive electuary, viz. four ounces of each dissolved in warm ale or water, and repeated every other day, with scalded bran every day, till the horse's body is thoroughly opened, giving him, at the same time, air and exercise. Oily clysters may also do service in this case; and, after these things are complied with, two or three purges may not be improper.

COVEY of PARTRIDGES, consists of the cock, hen, and their produce.

COUGH, CHRONIC, observes Mr. Blaine, considered as an action generally, is a violent effort of the diaphragm, intercostal, and abdominal muscles, producing a forcible expiration of the air from the chest, with such violence as is intended to remove any extraneous body that may intercept the free passage of the air. Whenever it accompanies a general affection of the constitution, it is regarded as simply *symptomatic*, and the original disease is attended to for its removal. Thus catarrh and pneumonia are frequently accompanied by a cough, but we attend principally to the inflammatory state of the general circulation, as the best means of subduing it. A chronic cough is no less symptomatic of some affection of the air passages, yet as it is the only prevalent symptom, the mitigation of which removes most of the ill effects of the complaint, so in this instance, though we do not neglect the cause, we attend to the cough also. Chronic cough is a very usual attendant on thick wind, and on broken wind: it likewise accompanies glanders and pulmonary consumption.

Worms also within the stomach and bowels are productive of a fixed cough. But besides these, there exists at times, without any attendant difficulty of breathing, the horse eating well and thriving, a permanent cough, usually more considerable in the morning and evening, after meals, and on any violent exertion, particularly on going out to exercise. A cough of this description is very common, and it will remain in this state, without otherwise affecting the horse for years, sometimes even his whole life. In other instances it does not end in so harmless a manner, but upon any occasional cold taken, becomes aggravated; at each cold becoming worse and worse, till at length the wind is affected.

I have frequently seen chronic cough benefitted by a course of mercurial physic; but the cough in such cases was probably dependent on worms: and, whenever a continued cough exists, with irregular appetite and unthrifty coat, stools foetid and slimy, at one time loose, and another hard and dry, it is more than probable that worms occasion the affection. In all chronic coughs the best effects sometimes follow from feeding with carrots. Turnips, parsnips, beet, and potatoes, may be beneficially used where carrots cannot be got; and a mash with bran and linseed, or malt, may be occasionally given. See CATARRH.

COURSING. This diversion, which has been practised from the earliest periods, was formerly more diversified than at present; that is, the greyhound was used to pursue the stag, the wolf, and the fox, as well as the hare; or, at least, so we are informed by those who have handed down to us their excogitations through the medium of the press.

However, it is not necessary to proceed beyond the length of the preceding few lines in an useless attempt to fathom the boundless abyss of antiquity, since we are very well aware that coursing has been, for many years, and still continues to be, confined to the pursuit of the hare. We know, further, that it has been much cherished of late years; that it has assumed a form and consistency; that it is patronised by the great and good, and consequently demands particular notice in this place.

In an interesting little volume, entitled the "Courser's Companion," the author says "coursing is followed by different individuals, or by different parties, and for different purposes: some for the pur-

pose of what hares they can kill for the table, and totally indifferent as to which greyhound has the most essential qualities towards obtaining that object, so that they do but obtain it; others for pastime, recreation, or getting out into the open air for the benefit of their health; others from a laudable emulation to vie with their neighbours and friends, as to which can produce the best greyhounds; others for gambling purposes; others for all these united, or for different portions of them.

Further—"Experience shews that discontent is a very prevailing matter at coursing meetings, and may be attributed to a variety of causes, as well as from the difference in the dispositions of men. Select five persons from out of a field of sportsmen, and ask them to describe the particulars of some one course to which they have all been eye witnesses; and it is great odds but that they will give you five different histories of it. This may be ascribed to different causes, amongst which, firstly, it must be remembered, they do not all view the course from the same situation; some at a greater distance than others; some to the right and some to the left; some before the dogs, some behind them; others opposite, others in an oblique direction; and the course, changing its direction, changes the direction in which different parties view it, continuing in the kaleidoscope manner throughout the course; and many circumstances taking place in it which appear different as viewed from different situations; it is, therefore, not surprising that different opinions should be formed of it. But when, secondly, this variety is increased, or rather multiplied by cross multiplication, with the variety of opinions held upon the principles or rules for deciding a course, for want of a regular, known, and acknowledged set of rules, it would be matter of surprise if *doctors* did *not* differ upon it. Thirdly, there are those who would wish to give an impartial opinion, but are over-ruled by the pardonable, because naturally-felt, prejudice or partiality, towards their own or friend's dog; in the excitement of the course, and the interest they feel in it, they anxiously watch every advantage *he* gains, which is impressed on their minds in a stronger manner than the advantage his opponent gains. And, fourthly, there are those, 'that go to win through thick and thin.' If they cannot win fairly, they will win, or try to win, by clamour—

they *cannot see* what points the opposing dog gains; but what their own gains *they can see even double*; or they will swear that their dog gained those very points which the opposing dog actually had gained.

To provide a complete remedy for the two latter would be as difficult as finding out the philosopher's stone; but the inconvenience arising from them may be much lessened, by remedying, as far as remedy is possible, the two former causes of the difference of opinion on a course. The first, by a competent tryer, sufficiently well mounted to keep a proper situation for seeing the whole course, and in whom the field have confidence, so that they will make allowance for the difference between his situation for viewing the course and their own. The other, by a code of laws, more simplified and more clearly understood, more generally known and acknowledged than what has hitherto existed." Unfortunately, however, for the first of these propositions, there are situations where a mounted tryer, or judge, though he rode the best horse in the world, would not be able to keep so well in with the dogs, as to be able to form a clear and decisive opinion; and this too, perhaps, where the very best dogs in England strive against each other:—As a pre-eminent instance, we may select Altcar, where the hares are very numerous, very stout, and the dogs at least equal to any in the kingdom. The Altcar Coursing Society, or Meeting, was established under the superintendence and direction of Lord Molyneux (eldest son of Lord Sefton) and is continued with much spirit; but the nature of the ground is such, that horsemen cannot ride to the dogs. The sport takes place upon an extensive flat, which, I should imagine, at some remote period, was covered by water and formed a mighty river. Time, however, (assisted by improved cultivation) has so altered the face of things, that the mighty river has dwindled into a small stream, of some three or four yards broad, which at present is known by the name of the river Alt. From what has been stated, it will easily be perceived that the ground lies low; and in order to render it as far susceptible of cultivation as possible, it is intersected in every direction with large ditches or drains, the banks of which are so very spongy and soft, that it is very difficult, and, for the most part, impossible, for a horseman to cross them:—if a horse sinks in these places, it is, in general, no easy

matter to get him out—the neighbouring peasantry, cart ropes, &c. are called into requisition for the purpose; and yet, notwithstanding the utmost exertions of the united body, the animal becomes exhausted, and sometimes almost dead, before he is extricated from his perilous situation. In fact, the Altcar Coursing Meeting takes place upon a well-drained bog, which affords the best possible view to the company, but where horsemen cannot follow, or keep in with, the dogs.

“It frequently happens, that the principle on which courses are decided varies in different countries and over different grounds. Much of the dissatisfaction arising from this cause would be removed by having *one uniform code of laws*, established and recognised by all public meetings for the guidance of umpires; an error could then only arise from the view taken of the course. The Ashdown Park Club have promulgated certain Laws of the Leash, expressive of the principles on which they wish to have the course decided; and if those, or any others that were thought by the leading clubs to be more perfect, were adopted generally, much advantage would accrue. But we may safely appeal to the facts upon the question; and the truth is, that more harmony and pleasure cannot exist in any society than in that of a coursing club. The mortification and chagrin which the loser may feel at the moment, give way to his respect for his brother coursers, and are more than counterbalanced by the beautiful style of running and performances of another dog from his own kennel. It is likewise true, that in every large society may be found spoilt children of a larger growth.”

Speed and the power of maintaining it should always form the leading characteristic in a greyhound; while *turning* is a most important consideration in fixing rules by which courses should be decided; “but one dog being a better turner than his fellow, has no need to have the advantage of a casting point in his favour, as he, in fact, *pays himself* by subsequently gaining a greater number of points, from being possessed of that faculty; nevertheless, turning requires much consideration, as the stoutness of a greyhound is ascertained by his enduring a number of turns in succession, one dog being much sooner tired with them than another. It may be said that this is owing to one being of a better breed, or in better condition than the other.

That breed or condition will shew itself in a greyhound's racing, as well as turning, must be admitted, although turning will bring it to the test the soonest. Suppose a case:—two greyhounds of the same breed and the same litter, when they have been fairly entered one season, and found equally good in their trials, then, when they are commenced training for the next season, let one of them be exercised wholly by running him by the side, or with, horses, without running him a single course till his trial day: the other run with horses for a part of his exercise, and the other part with coursing, so that the muscles and parts brought into action by turning, are exercised and strengthened. These two dogs, in other respects fed and trained alike for a few weeks, may be brought to trial; and it will soon become apparent that turning distresses the one not exercised to it much more than it does the other; and, therefore, that turning has an effect upon dogs which requires due allowance. Experience also shews it in other cases.—Two dogs of the same breed, equally good for speed and turning, but one of them in worse condition than the other; that defect in condition, it will be admitted, will begin to shew itself in some stage of the course or other:—a close observer will first perceive that defect by the dog shewing less quickness, activity or vigour, than the other in recovering from his legs upon a turn, and thereby shewing that *turning* has an extra tendency towards lessening his powers.

Also, take two dogs of the same breed and condition, but one slower than the other, supposing them both fair runners: the slower dog will give more turns than the *latter*, while the speedier dog will exceed his fellow in this respect at the *first* part of the course, and thus reduce his power to a level (or even below) the slower dog. It does not, however, always follow that because a dog gives the most turns at first, he should be defective at the last part in comparison with his fellow, from the distress occasioned by those extra turns, where his breed and condition are good; as the powers of a dog will weaken faster in a course, or become more visible, by a defect in breed or condition, than by the extra exertion of turning where there is no such defect; and, therefore, if the more speedy dog has also the advantage of breed and condition on his side, he will maintain his superiority, to a certain degree, independent of his

undergoing the extra exertion of giving the most turns.

Where it is evident, from a number of turns, that they weaken and distress a greyhound, it must be allowed that *one* turn only, though the weakness caused by it is not visible to the eye, has its due proportion towards lessening his powers for the subsequent part of the course; and though that portion may be trivial, and what takes place in the course afterwards may be trivial also, yet there is no drawing any other line, than allowing for it in the regular ratio, and that principle ought to be followed in all other single or trivial circumstances that occur, otherwise the principle would become a dead letter.

Should there occur nothing in a course upon which to decide but a superiority of speed, it becomes highly important that the judge or tryer should be in a proper situation for observing it. To many persons in the field it may appear that the last dog gains upon the first, when in reality he does not gain; and this impression arises from the situation whence it is viewed: if the dogs are running in a direction straight from you, or obliquely, it will appear so, because the actual distance between the dogs appears to diminish the further they get from you, when, in fact, the distance or space does not diminish in the least; and it will also appear that the first dog does not gain when he actually is gaining. If you are situated laterally; that is, the dogs presenting a complete side view; or what the author of the "Courser's Companion" calls "directly opposite," at a moderate distance, you will easily see which of the dogs gains upon the other; but to those who continue stationary, this exact lateral direction can only be momentary, and the greater the distance, the less perceptible is any trifling advantage.

From twenty to forty yards to the right or left of the dogs is the best situation for the tryer or judge; which distance will not only enable him to observe the superiority which one dog may maintain over the other, but also whether the course is a straight stretch, or the hare running in a bend, which cannot be perceived by persons who are at a great distance to the right or left.

It sometimes happens that one dog is behind the other in the first run up to the hare, from their not starting equally together, and without any fault of the last dog. By some this is held that it ought to be looked upon as the fate of war, and

that the other ought to be allowed what he gained by it. The fortuitous circumstances which occur in coursing are numerous and frequent; and it may be contended that the most simple way would be, to allow every dog the advantage and points he gains, whether gained by merit or by chance.

Merit in a greyhound is by comparison with the one with which he is contending. By superior speed he gains go-bys, cotes, turns, &c. and by stoutness he is enabled to continue them: by being a good turner, fencer, or killer, he gains more points than one inferior in those capacities. Of these points, a go-by, a cote, a kill of merit, a tripping, a jerking, a turn, and a wrench, may be called fundamental. Superior speed, a fair runner against an unfair runner; a good fencer against an inferior fencer; giving a succession of cotes or turns in the middle of a course, may fairly admit of being allowed as extra points where the fundamental points are equal. An unequal start, an inside turn, or hare going in a bend; not seeing the hare when slipped, or dissighted from other accidental causes; a fresh hare getting up; a third dog slipped; a dog rode over, or running against horses' legs or other things, whereby he is disabled; are casualties that should be decided by the judge according to the circumstances of the case. Where the judge is unable to form a decisive opinion, the matter ought to be settled by a toss.

The hares at Amesbury, as well as many other parts of Salisbury Plain, have, and deserve to have, the character of extraordinary speed and stoutness; and though it may appear incredible to many, from the apparent superiority of the greyhound in stride and muscle, yet it is an incontrovertible fact, that, with a fair start, many a hare has run a brace of greyhounds out of sight without being once turned. Sir Walter Scott, speaking of the hare of Balchristy, says—"She usually gave the amusement of three or four turns, as soon as she was put up (a sure sign of a strong hare, when practised by any beyond the age of a leveret) then stretched out and so forth." This disposition to play with the dogs, in a strong hare, is sometimes practised to a much greater extent than three or four turns:—they will "kick up their heels in the face of the dogs after ten or a dozen turns, immediately tip them *leg-bail*, and run them out of sight." The fact would appear to be, that these strong

hares cannot, at starting, exert their best pace; but, after having been on their legs a few seconds, they gain their utmost speed and use it accordingly.

With a hare of this description, if the principle were to be admitted of allowing more for the turn given towards the covert than from it (which appears recognised in the new Laws of the Leash at Ashdown Park) where is the chance of a fair running dog contending with success against a waiting one? They may, in other respects, be equal, when loosed from the slips, but by the waiting dog saving himself, coming in for turns or wrenches, when his fellow, in a manner, brings the hare to him; his fellow exerting himself to the utmost of his power, undergoing severe twists of the body, by striking at the hare, and she doubling short back, as such a hare will do, the course she gives them afterwards, affords the waiting dog an opportunity of shewing the superiority or strength which has been left in him by saving himself—it may enable him to reach her, when he otherwise would not have done, and gain one or more turns; and, if not, he will probably manifest such superior speed in the race, as will, in a manner, eclipse any extra turn or two which the honest running dog may have gained at the commencement, more especially if it be not a fixed principle to take every point or turn throughout the course into account.

That *the best dog ought to win* is a maxim which should always be kept steadily in view; and that dog which performs the most towards killing the hare, it would seem reasonable, ought to constitute the best dog. The dog which gains the greatest number of points would appear to be the soundest principle upon which to act in the decision of the tryer or judge. It nevertheless may sometimes happen, that the best dog gains the fewest points, owing to accidental or fortuitous occurrences; yet this circumstance should not be allowed to disturb the acknowledged principle.

We shall introduce, in this place, the Rules of the Ashdown Park Coursing Meeting, which, however, would appear little more than riders to the old code promulgated by the Duke of Norfolk in the reign of Elizabeth, which appears under LAWS OF THE LEASH.

*General Rules for the guidance of umpires in deciding courses, and other Laws of the Leash, sanctioned by the members of the Ashdown Park Coursing Meeting, present at Lambourn on the 7th Feb-*

*ruary, 1828, and inserted in the Cours-er's Manual, or Stud-Book.*

1. A brace of greyhounds only to be slipped after a hare.

N. B. The slipper should be a horse's length in advance of the beater, and when a hare is started he should quicken his pace, that the dogs may both take sight, and pull in the slips before he looses them. It is necessary that good law should be given, as it materially assists the umpires in case of a weak hare.

2. If a second hare be started during a course, and the dogs divide, the course to be given to the dog that follows the slipped hare.

3. If there be only one turn and a kill in the course, the dog that gives the turn shall win, if it be a fair start.

4. If there be no turn or kill in the course, the dog that gets first to the covert shall win, for cup or sweepstakes.

5. If there be many turns in a course, a go-by shall be equal to two turns of the hare. The lead-up to the hare from the slips, and the first turn, shall be equal to two after turns of the hare. Two re-wrenches of the hare, provided the dog makes them following without losing the lead, shall be equal to one turn. The turn, when the hare is leading to the covert, shall be considered more than the turn when she is running from the covert, provided the number of turns be equal. If a dog falls in the course when he is leading, he shall be allowed a turn more than he gives.

6. If one dog follows the hare home, and the other stands still when the hare be in view, the course shall be given to the dog that runs home, though he had not the advantage in running. If both dogs stand still in a course, it shall be adjudged to the dog that runs longest after the hare.

7. If both dogs be unsighted owing to a hare running through a bush or bushes, furze or plantation, so as to impede the course, the course shall be deemed to end there.

8. If the owner of either dog, or his servant, ride over the dog of his opponent in the course, he shall lose the course.

9. If a third dog get loose and join in the course, the course shall stand good and be decided, and the owner of the third dog shall be fined according to the rules of the club.

10. The umpires shall give their judgment promptly, before they converse with others in the field; if they be divided in

opinion, they should ride apart from the rest of the company until they have consulted a third person, who should be chosen in all courses, for cup and sweepstakes.

11. If the dogs be slipped at a hare, and they are unsighted, and before they are taken up another hare start, so that the dogs are fairly laid in, it shall be deemed a course as though the dogs went from slips.

In justice to the author of the "Cours-er's Companion," whose little book is the production of a man of sense, we must quote the code which he proposes for general adoption:—

*Laws of the Leash; or, a Code of Coursing Laws, as proposed to be amended from those framed by his Grace the Duke of Norfolk, in the reign of Queen Elizabeth.*

1. A hare ought not to be coursed with more than a brace of greyhounds.

2. She ought to have four or five score yards law before the dogs are loosed from the slips, if the nature of the ground will admit of it without danger of losing her.

3. The slipper ought to have only one person to obey when to slip them.

4. The tryer ought to be in a situation to see if both dogs go together out of the slips; and he would be the fittest person to judge of the distance the hare is off, and to give the word *slip*.

5. The slipper ought to run forward with the dogs when a hare gets up, so that they will bear steadily against the slips, otherwise one or both may be turning round at the time the word slip is given.

6. When a hare is found sitting, she ought to be distinctly soho'd, as the dogs may be alive to her getting up; and for the same purpose she ought to be halloo'd when started; the latter ought to be only by one or very few persons.

7. A cote to be reckoned two points; and a cote is when two dogs start even together, the hare going in a straight forward direction, and one dog draws endways by the other, and gives the hare a turn.

8. A turn to be reckoned one point; but if the hare turneth not, as it were, round, she only wrencheth; and two wrenches are equal to one turn. A wrench is when she strikes off to the right or to the left, at about a right-angle.

9. A go-by to be reckoned two points; but one dog being behind the other and then getting first, by the hare going in a

bend, or any way unless in a fair straight-forward stretch, or by superior speed, is no go-by, but an inside turn. If a dog gives half a go-by, to be allowed one point for it, unless that half of a go-by forms part of a cote, in which case it should be reckoned in the cote.

10. Killing the hare, or catching and holding her, to be reckoned two points, if it be a kill of merit; but one dog turning the hare into the other dog's mouth, or other casual circumstance causing it, the kill to reckon only one point or nothing, according to the degree of merit the tryer considers to be shewn in effecting it, or no point if no merit in it.

11. A tripping, or jerking, the hare to be reckoned one point.

12. If a dog takes a fall in a course when he is leading, he shall be allowed one point more than he gained.

13. If one dog does not see the hare when slipped, by any accidental occurrence not *his* fault, to be deemed no course; but if owing to his own untractableness or infirmity of sight, the dog that follows the hare to win.

14. If there is no turn or other point gained, an equal start, and the hare going in a straight-forward direction, the dog leading first to the covert by superior speed to win. If one dog loses ground at the start, by any occurrence *not* his own fault, and afterwards evidently gains upon the other by superior speed, though he does not pass, or get even with him, yet he ought to be deemed the winner. Either dog leading first to the covert by an unequal start, an inside turn, or other occurrence where there is no superiority of speed shown, the course to be adjudged dead; but if the unequal start was owing to the fault of the dog, losing ground by it, and who does not regain that loss by superior speed, he ought to forfeit the course.

15. If a dog loses ground in the start by any untoward circumstance, *not* his own fault, and yet maintains equal speed with the other, if that other gives the hare a turn, or gain any other point, but the course end immediately by the hare getting covert, sough, squatting in turnips, or otherwise, except killing her, that turn or point not to be allowed for, but the course to be adjudged dead. The same if that turn was gained by the hare going in a bend or otherwise, without any superiority of speed being shewn. If the course continues longer, and other points are gained, that first turn or point to be taken into the account; and if that

unequal start was owing to the dog's untractableness, or otherwise his own fault, the turn or point gained by the other dog to entitle him to win, though no other point was gained.

16. If a dog stands still in a course, otherwise than through distress, or leaves the direction of the course for the purpose of meeting the hare, the points he has gained to be reckoned only up to the time he stood still or left the course, though he may afterwards join in it. If the points he has gained up to that time should happen to equal what the other gained in the whole course, his standing still, or leaving the course, to give the extra point against him.

17. If a dog refuses to fence where the other fences, his points to be reckoned only up to that time, though he may afterwards join in the course. If he does his best endeavour to fence, and is foiled by sticking in the meuse, or the fence being too high to top it, whereby he cannot join in the rest of the course, such course to be deemed to end at that fence. And should the points be equal, a good fencer to have an extra point over a bad one.

18. If a fence intervenes in a course that the tryer cannot get over, and thereby loses sight of the rest of the course, the course to end at that fence.

19. If a dog be rode over, or disabled, so that he can proceed no further in continuing the course, by other accident not the fault of the owners of either dogs, or their servants, the course to be decided up to the time the accident occurred; but if the fault of the owner of the other dog, or his servant, to be given against him.

20. If a fresh hare gets up during a course, and one of the dogs takes after her, the course to be decided up to the time she interfered with it. If a third dog gets loose and interferes with a course, to be decided in like manner, unless the third dog is the property of the owner of one of those engaged in the course, in which case the course should be given against him.

21. If the points be equal between two dogs, but one evidently shows most speed, that speed to entitle him to the extra point; but where one dog has a majority of points, and the other most speed, the majority of points to win.

22. The next brace of dogs to be taken to the slipper immediately on his

loosing the other dogs, that he may have them ready in the slips when the tryer returns from the course; but they ought not to be slipped at a hare until both the other dogs are taken up, for fear of their joining in the fresh course.

23. Some one person should be appointed to receive the tryer's decision, and to communicate any directions to him upon the orders of the field. No other person ought to interfere or say a word to him during the time the business of the field is going on, as it is his place to judge upon the points of the course, as well as the casualties that may have occurred in it. Should the owner of either dog engaged, or their servant or partisan make any remark to him, either directly or indirectly, before he has given his decision, he ought to forfeit the course, though it may be that his dog was entitled to it.

24. A tryer ought to have a quick eye, a clear head, and a retentive memory; and ought to give his judgment promptly and decisively, but not over hastily. No one ought to ask him why he decided on such a dog, nor ought he to answer them if they do ask him, without their first applying to the stewards, and who ought not to suffer him to be annoyed with questions which they, the stewards, think unnecessary.

CRACKS in the heels of horses, during the winter season, are found only in stables where the master seldom or ever condescends to appear. These trifles are too frequently attributed to a defect in the constitution of the horse, when, with more propriety, they might be fixed upon a want of constitutional punctuality in the groom. Horses left with wet legs and heels after chase or journey, particularly in sharp easterly winds, or in frost and snow, produce the evil to a certainty.—So severe a rigidity is occasioned in the texture of the integument, that it becomes partially ruptured, (or broken in various places,) upon being brought into action the following day: this, with the irritation and friction occasioned by the sharp particles of gravel and extraneous matter in the dirty roads, soon produces enlarged lacerations of the most painful description. The prudent part of the world will always consider, as well in this, as in every other case, that prevention is better than cure: servants should be allowed in the stables, linen cloths for rubbers to the heels, that they may never be left in the

least wet, particularly in the winter season, when once getting tender, the stubbed ends of the new and stiff straw frequently occasion or increase such lacerations.

**CRAMP** is a most extraordinary spasmodic muscular contraction of some particular limb, where the stiffness and rigidity of the part exceeds belief. To those who have never been accustomed to such cases, they are serious and alarming; for the strength of two men is inadequate to the task of rendering the affected limb pliable and active. The cause is sometimes not to be ascertained; but it has frequently arisen from a horse, in a high state of perspiration, having been placed in a current of cold air, or a damp stable, and in a few minutes found not able to move. Standing still two or three days in succession without exercise, after long and constant travelling, is likewise known to produce it. But whatever cause it may have originated in, the direct road to relief is still the same. Instantaneous bleeding, hot fomentation with a decoction of aromatic herbs, immediately followed up by strong friction with an old stable horse-brush, and this by an embrocation of camphorated spirits, half a pint, incorporated with one ounce of oil of origanum, and a part of it patiently rubbed in upon the particular part affected, never fails to relieve in a short time.—Should it, however, not take effect, so soon as expected, dissolve a cordial-ball in a pint of gruel, to which add an ounce of liquid laudanum, and let either or all the operations be repeated in a few hours, should the case (or a relapse) require it.

**CREST-FALLEN.** A horse is said to be crest-fallen, when the part running from the withers to the ears, and upon which the mane grows, is impoverished, and wasted from the natural prominence of its beautiful curve, to a state of reverse hollowness or indentation. This is generally accompanied by a total emaciation, brought on by very bad support, or neglect under different degrees of disease.—The firmness and corresponding curve of the crest is almost invariably a tolerable criterion of the health and condition of the horse; and a judicious inspector seldom omits this part of the examination.—If the flesh upon the crest is firm, solid, and not flabbily soft, or fluctuating, it is a good sign of constitutional strength; but a horse having a low, bare, indented crest, will always have a poor, weak, and im-

poverished appearance, doing his owner no credit. This defect, however, proceeds more from penurious keep, and temporary starvation, than any cause or defect in nature, and may always be expeditiously remedied by liberal support, and nutritious invigoration.

**CRIB-BITING** is a habit of continually biting the manger, and gulping the wind. Mr. Yare, inventor of the anti-crib-biter, makes the following judicious observations on the subject in the *Sporting Magazine* of July, 1830. — “Crib-biting is often produced by injudicious cleaning. It is a common practice, in racing and hunting establishments, to dress horses with an ash stick in hand, which is held at them *in terrorem* whilst undergoing that process, and occasionally applied to their bodies with rigour. This practice is not only foolish, but betrays a want of judgment which nothing can extenuate; for the unruly conduct of the animal is mainly attributable to mismanagement and ignorance on the part of the attendants themselves, who very unjustly make the horse pay the penalty of their own awkwardness, as I can easily shew. Grooms and stablemen often disregard the irritation they cause to horses in passing too roughly with comb, brush, or wisp, over the belly, flank, and under the web of the arm, which on those tender parts produces extreme titillation. The animal, unable quietly to endure this oftentimes prolonged excitement, in the agony of his suffering naturally enough resists, and evinces his displeasure of the treatment by reiterated attempts to kick and bite the party inflicting the torture, as well as laying hold of the manger with his teeth, which in many instances is undoubtedly the forerunner of crib-biting. On these occasions the ash stick is brought into unmerciful requisition, thereby spoiling the temper of many of our best and finest horses, who, compelled diurnally to undergo this teasing ordeal, generally become spiteful and ill-natured, and, in addition to other vicious propensities, imbibe a mischievous habit of kicking out on the approach of any person towards them. Now, if the groom would only reflect for a moment, he would be immediately convinced that his own improper conduct was the cause of the trouble experienced, and that his irrational proceeding must ultimately ruin the most docile and quiet horse; but the despotic character of man misleads him to imagine, that the brute

animals must implicitly obey and acknowledge his supremacy as a law of Nature, and submit to his will subserviently, even though intimated to them in a somewhat ambiguous manner. I cannot with propriety be contradicted, when I state, that so long as this baneful system of stable-management and discipline be allowed to be pursued with impunity by servants, gentlemen may always make sure of possessing crib-biters and vicious horses.

The precaution which I invariably observe is, never to dress, buckle or unbuckle girth or roller, with the head to the manger, or, if in the open air, within reach of any thing the horse can snap at or lay hold of; uniformly taking care that he be soothed or kindly used when undergoing the operation of cleaning; and, should resistance be opposed when passing even as lightly as possible over the parts above mentioned, I never allow any violence to be enforced. By this usage, the animal is not only less troublesome to the attendant, but the kindness of his disposition is preserved unbroken.

Vicious habits may likewise be ascribed to imperfect training. For instance: a horse is entrusted for that purpose to the care of a person totally unacquainted with the manner of treating him, consequently incapable of judging whether the horse be qualified by nature to fulfil the intentions of the owner. The age and strength of the animal have not been taken into consideration; and his incapacity to undergo the fatigue allotted to him, although proceeding from weakness, has very incorrectly been ascribed to stubbornness and obstinacy. Resistance, as may be expected, has been the natural consequence; harsher usage has followed; the temper of the animal has become soured; and he has really imbibed a vicious character, which at the onset was only imaginary. The result has been open warfare between him and his rider; in which the latter seldom gained an ascendancy; and the former has never been duly trained for the purpose for which he was destined; indeed, he has frequently been rendered quite unserviceable, and become afterwards a drug in the market, though nature had intended him to be useful in many capacities, which, under judicious management, would doubtless have been realized.

The nature of instruction requires that he who teaches should be intelligent, and know how to make himself understood

by his pupils, otherwise little good can be attained. This is more essentially requisite in the rearing and tuition of an irrational animal. When the teacher knows but little himself, or has not the talent of imparting knowledge to his scholars, the design of education is not fulfilled, and coercive measures only aggravate the evil. A parity of reasoning will hold good with horses.

For a long series of years I have been in the habit of making observations on the errors committed in the usual treatment and training of horses; and I am convinced, from experience deduced by long study of the nature of horses, and continual intercourse with them, that mild discipline is the *sine qua non* of stable-management, and it is the interest of every proprietor to see it enforced. Patience and good temper are cardinal requisites in a groom. Horses have very retentive memories, and seldom forget the unruly tricks or habits acquired from improper and hasty handling.

I have just observed that crib-biting is oftentimes caused by improper dressing. It also very generally dates its origin, according to the observations I have personally made, to want of employment, as well as to imitation.

Bad habits usually result from idleness. If we are inveterate smokers or snuff-takers, let us ask ourselves the reason of our indulgence in these propensities? For the moment, probably, we cannot account for them; but, after a little reflection, are free to admit, that imitation and too much leisure are the causes; and custom has tended to root us so firmly to these habits, that to be debarred their indulgence would to many persons be downright misery. As with man, so it is with the horse.

A crib-biter, or wind-sucker, should never be turned out to grass promiscuously with other horses, for he most assuredly will get at the land marks and gates; and, whilst indulging in his propensity, will naturally attract the notice of his companions. Imitation, as I said before, is one of the leading inducements to this destructive habit. I was once an eye-witness to the fact of a horse, when in the field, drawing the attention of four others from amongst the number grazing to his actions. They alternately began, first to nibble at the place moistened by the saliva of their comrade, and, as I prognosticated at the time, became afterwards confirmed crib-biters.

A horse, from want of exercise, will often take to cribbing from sheer idleness, or too much confinement in the stable; and the abominable practice of tying the head to the rack produces, particularly in young high-couraged horses, an impatient restlessness. Some shew their dislike of the restraint by continual kicking with one or the other of the hind legs; others, by nibbling the rack or manger, till they imbibe a professed attachment to the vice, more especially if, in the adjacent stall, they have a companion addicted to crib-biting, and themselves a nice soft deal manger, inviting them to enter upon their noviciate.

Confinement in the stable for too long a period has a similar effect on the horse, as too great an indulgence of bed has on the human frame—it produces general debility and weakness. My advice is, when the horse be not wanted for service, to give him walking exercise in the open air three or four hours a day, allowing him plenty to eat and drink; and if this do not keep him hale and fit for use, why, *get rid of him*, as, to borrow a stable phrase, ‘he must be rotten.’ When the weather will not permit of exercise in the dry, put on a soft bit with players, for two hours in the morning and two hours in the afternoon; by an adherence to which rule digestion is promoted, the loss of exercise compensated, and, by the amusement the horse finds in the bit, he is not only kept out of mischief, but the carriage of the head is greatly facilitated. Exercise improves the appetite and strengthens the power of digestion in a surprising manner; hunger becomes keen; and food is taken with eager relish, which is well known to be one of the best signs of health.

I have occasionally excited the ire of grooms, by requesting them to abandon the practice of using the rack-chain. These gentlemen, when interrogated as to the utility of attaching the head to the rack, usually answer, ‘To prevent the horse lying down and dirtying his quarters!’ But the true reason is, they are fearful of a little extra trouble in case the animal should be wanted at a short notice. When I have inquired if the horse was habituated to lying down in the day-time, or whether he has been ever known so to do, the response given is usually, ‘No; we never actually saw him down during the day, but we have always been accustomed to tie him up.’ Therefore, according to their own shewing, they

give the poor beast his unnecessary restraint from no other cause but custom, which they blindly and implicitly follow, though they can adduce no benefit resulting from its observance. Custom and prejudice are most imperious tyrants, and rule triumphant over horsemen, as well as other classes of society. There are certain points established, certain axioms laid down, and the nine people out of ten, who never think for themselves, take every thing upon credit, and implicitly fall into the regulated course of opinion generally held, without stopping to inquire whether it happens to be just or unjust, tolerably right or entirely wrong.

If the horse be addicted to lying down in the day-time, I have generally found, on inspection, that he is either sick or lame, and consequently required immediate attention. Now, to tie horses to the rack under such circumstances, is obviously an act of cruelty. In my opinion, to attach any horse to the rack only serves to pave the way for the occurrence of those habits and vices which have for so many years baffled the attempts of horsemen to prevent, correct, and eradicate with certainty and permanency.

Many continue pertinaciously to assert that crib-biting is not injurious to the strength of horses. I am free to admit that they sometimes go through very arduous tasks and fleet performances, and may probably occasionally win a race; but capability of exertion would be still more evident, and the rapidity of his course increased, if the malady were removed. But no positive reliance can be placed in the exertions of a crib-biter or wind-sucker; for the natural power and ability of the animal must inevitably be weakened, and ultimately yield altogether to the ravages the indulgence of these propensities occasion on the frame of the animal, if prosecuted for any length of time.

A horse may be addicted to cribbing, and yet its pernicious effects shall not be perceptible, except to those who are thoroughly acquainted with the symptoms incidental to, and which uniformly accompany, the practice of the habit. I have known many horses labouring under this malady, whose condition appeared so good to the casual observer, that their owners have doubted my allegations as to their weakness; but a little extra exertion, in company with a sound horse of apparently equal power and capability, soon convinced the party of their error—the

strength of the crib-biter, after a short trial, proving very inferior to that of his opponent. I know well that horses indulging in the propensity must of necessity be injured or impaired in their stamina. Acting upon this calculation, when attending races, and accidentally discovering that any particular horse was either a crib-biter or wind-sucker, although he might be a 'favourite,' to use a turf phrase, 'I uniformly back him to lose, and am generally right.'

I have no hesitation in saying, that a crib-biter is *bona fide* an unsound horse; and notwithstanding the warring litigations that may have occurred occasionally in consequence of the habit, when a totally opposite notion to mine has been entertained on the question, yet I cannot avoid arraying my individual opinion in opposition to the fearful host of dissentients who may start up against me, when my assertion is perused. *I verily believe that a crib-biter, sold with a warranty of soundness, is, to all intents and purposes, returnable:* and I think I cannot be accounted unfair or erroneous in this position, founded on the well-ascertained fact, that 'crib-biting horses are injured in their stamina.'

That Nestor among veterinarians, Mr. Bracy Clark—to whom the horse is so greatly indebted, not only for his valuable publications, but likewise for the discovery of many parts and properties of the foot of the horse, and, above all, his perfection of the expansion shoe—observes very truly in his remarks on this subject, that 'the crib-biting horse has generally a lean, constricted appearance, the skin being contracted about the ribs; or a sunken watery eye, or else too dry; the muscles of the face also, as well as the skin, drawn up with rigidity. When unemployed in eating, his almost constant amusement is to grasp the rail of the manger with his front teeth, then to draw himself up to it, as to a fixed point, by a general contraction of the head, neck, and trunk; at the same time the effort is attended with a grunting sound.'

Now, many veterinary surgeons are of opinion that the particular noise made by the horse is caused by the expulsion of air, and that crib-biting is in fact nothing more than an effort at eructation, arising from indigestion or some viscid state of the stomach; whilst others pretend to say, that the habit is caused from pain in the feet. If either of these opinions were correct, to remove the destructive propen-

sity, recourse must necessarily be had to the *Materia Medica*, and the animal should be treated according to the rules of veterinary science. That these judgments must be erroneous, I prove clearly by the system I have established, which enables me to eradicate crib-biting and wind-sucking without the aid of medicine.

My attention, as I have before stated, has been directed to the prevention and cure of this destructive malady during a long period; and although I may dissent from many very respectable authorities, I must remark, that, during the whole course of my experience, I have uniformly observed that a crib-biter (as well as wind-sucker) inhales air into the stomach, which, from its construction, he cannot exhale or degurgitate; for horses, unlike dogs and many other animals, can neither belch nor vomit, consequently in its progress through the stomach and bowels, the oxygen, or elastic property of the air, is taken up by the system, which causes a redundancy of fixed air in the abdominal parts—hence arises flatulency, which of course produces indigestion, general debility, and an impaired stamina; and these alarming effects, if not attended to and removed, must naturally lead to disorders of dangerous tendencies.

To broach an opinion of this import is, I know, in opposition to the sentiments entertained by many hippologists; and that I may be clearly understood by every reader, I have purposely avoided the use of scientific words or technical phraseology, and expressed my meaning in plain unassuming language.

Others, however, of acknowledged skill and ability in their profession have lately had the liberality to confess, that, on mature consideration of the subject, they considered I was correct, and encouraged me to proceed in my course.

With much labour, patience, and perseverance, I aimed at the discovery of the *proximate cause of crib-biting*. My studies have been practical, for I could meet with no satisfactory information in books. I made experiments of various kinds, repeated and improved them, and thus approached nearer to my object, till at length I had the pleasure of perceiving that I was in the right track.

That the crib-biter inhales more air into the stomach than he can exhale, I am convinced; and on that conviction have founded my system for the treatment of the malady; the application of which,

I may assert without presumption, cannot fail of success, if attended to with sincerity and good will on the part of the grooms and other stable domestics.

A crib-biter of any standing becomes soured in temper; his natural strength soon gives way; weakness more or less ensues; and he is rendered unfit for a proper day's work: yet horses labouring under the effects of this propensity are expected by their proprietors to perform the most violent exertions, and the fleetest and most rapid efforts are required of them! Hunting, racing, in short every duty is imposed indiscriminately with sound animals, till the poor beast sinks prematurely under his accumulated misery, and is thus rendered unserviceable many years before his natural term. Under kind and judicious treatment, the horse would be much longer lived than is generally supposed, as existing facts testify.

Various remedies, purporting to be infallible, for vicious horses have of late years been put forth to the world, but nothing has in reality been gained by them. I allude to torturing straps, bands, and other vexatious applications, which only tend to sour the disposition of the animal, and, on their removal, leave him more inveterately addicted to his evil habits. Others, from want of a better remedy, have recourse to loathsome and nauseous experiments, which are as futile as they are disgusting, and cannot possibly be expected to produce any permanently good effects; for as the matter or ordure employed dries and hardens, it naturally loses its effluvia, and consequently requires repetition to make the process adopted effectual, even if it were proper to pursue it. An accumulation of filth on the manger is the result; and we all know that that utensil should be kept particularly clean. I have no patience when I reflect on such proceedings. It is obvious to any one conversant with horses, that a filthy stable is the forerunner of disease. The only consequence emanating from conduct so inconsiderately ignorant is, that the silly attendant, for his own convenience, is soon compelled to remove the dirt, gaining nothing but additional labour for his assumed sagacity.

He who pretends to correct the horse, by inventing apparatus with that view, should previously study the nature and character of the animal, in addition to the contemplation of his own emolument. To exemplify this observation, let us con-

sider for a moment the fate of the straps with the spring and spikes. They were introduced under the protection of weighty patronage; and all that influence could do was adopted to facilitate their reception in the highest quarters, and render their adoption general. They were predominant for a time, and were probably esteemed by persons unacquainted with the matter, who received the *ipse dixit* of others as truth 'sacred as Holy Writ;' and accordingly the straps were considered and recommended by many persons as a certain cure for crib-biters. However, when essayed by those whose knowledge and intelligence could be relied on, it was discovered that they could never fulfil the object promised to purchasers, and not the most distant prospect of efficacy could be entertained. Their application only served to alarm, irritate, and tease the horse, without producing any beneficial effects; and, on their removal, he was generally found as inveterately addicted to his propensity as ever. A horse will never become tractable under fear, which is soon excited, as his timidity is proverbial. What is rational can only be attained by rational ways; and in nature an object cannot be compassed but by means consistent with nature. The straps were invented without any adherence to this maxim; hence their inutility and consequent downfall.

Covering the top of the manger with a sheep-skin, the woolly side outwards, is a remedy still in vogue amongst persons who act and move upon second-hand information. This insignificant process continues a favourite, and is very sagely recommended as a preventive in many of the provinces. I have more than once seen it used as a precaution, and in London too, above all places!

The execrable and infamous custom of burning the palate of the mouth as an antidote to crib-biting, cannot be too strongly reprobated, and must not be passed over in silence: but, without stopping to descant on the cruelty of this practice, I have merely to observe that the proselytes to it gained very little by their barbarity; as the horse is only checked so long as the soreness and tenderness caused by the cauterising exist, and no sooner has the pain subsided than he recommences operations. Should a gentleman discover the wound, the inflictors, ashamed of their proceedings, take special care not to divulge the real cause, but quibble and prevaricate, till at length I

have known them hit upon the expedient of informing an inquirer that the poor thing had been *seared for the lampas*, evincing by the subterfuge as much ignorance as they possess want of feeling!"

Before we conclude the present article it becomes necessary that we should say something respecting Mr. Yare's anti-crib-biter; and it would have given us the utmost pleasure could we have thought as well of the anti-crib-biter as we do of that gentleman's judicious observations, quoted above. But our duty to the public compels us to state, that the anti-crib-biter is not what it professes to be; *it is not* "an infallible remedy for the above vicious and destructive habit in horses." The anti-crib-biter is merely a muzzle; so formed, however, that the horse is enabled to use his lips and tongue, and thus to draw hay or corn to his mouth, without being able to lay hold of the manger with his teeth; while, therefore, the muzzle is on, it acts as a preventive from biting the manger, and nothing more:—and this, in fact, amounts to little. It does not prevent the animal from *sucking his wind* (as it is called); nor indeed, in the instances which have fallen under my observation, does it prevent the animal from performing a sort of intended apology for crib-biting. Take off the muzzle, and the horse immediately goes to his old work quite as eagerly as ever. Every attempt to remedy the disgusting vice of crib-biting is praiseworthy; and it was laudable in Mr. Yare to introduce his new invented muzzle; but when the instrument is represented as "*an infallible remedy for the above vicious and destructive habit in horses*," the assertion or statement is *grossly erroneous*, to say the least of it. If it is to be useful, the horse must constantly wear it; and even in this case, its utility is very doubtful. In a few years, I have little doubt, it will be entirely laid aside, if not altogether forgotten.

**CROPPING** of the ears of horses is exploded.

**CROSS-BOW**, an instrument superseded by the fowling-piece; at present occasionally used in rook shooting. The best cross-bow I ever met with belonged to a friend of mine, who took particular pleasure in what he called perfect shooting. As near as I can remember, its bow, commonly called the lath, was made of the best shear steel, of an oblong square, the segment of a circle of six feet, thirty-

six inches long: the *cock* which was attached to the lever is of ancient invention, and which yet defies improvement, was let off by the thumb of the left hand (which is better than by a trigger). Our distance of shooting was ten yards horizontal at a table knife, the back of which was sunk into a turf (or peat) and he who cut the most bullets in half a dozen, was acknowledged the best shot.—The balls were half an ounce each, the *setting* of the bow, as it is called, (that is, adjusting the two sights) should be, at the above distance, horizontal, and will then *answer* to shoot from the angles of thirty to fifty, with the same nicety. The lath should not be too strong, as it renders the diversion both laborious and painful. Lancashire only has been famous for the manufactory of cross-bows.

**CROWN-SCAB** is a partial appearance about the coronet of a horse, varying in different subjects, according to the state of the object diseased. It partakes a little of the disorder called grease, to which, if unattended to, it would soon degenerate; being a species of that defect, but in an inferior degree. In some it appears as a scurfy eruption, raising the hair, and turning it different ways, from whence soon oozes a kind of oily ichor, foetid in smell, and greasy in appearance: in others, the discharge is thinner, and more watery, according to the greater or less degree of morbidity in the frame, or acrimony in the blood. It has been a practice with the old school to counteract its effects by vitriolic lotions, slight styptics, and strong repellents: scientific disquisition will not, however, justify such treatment, but recommend daily mollification with warm oatmeal gruel and a soft sponge; when which is wiped gently dry with a soft linen cloth, it may be very mildly impregnated with camphorated spermaceti ointment, and the cure assisted by mercurial physic, diuretic balls, or a course of antimonial alterative powders.

**CRUPPER**, a leathern convenience, or long strap, annexed to the hinder part of the saddle, having at the other extremity a loop to pass under the tail; by which the saddle is prevented from getting forward, and bringing the rider upon the neck of the horse. Such aid is by no means required with horses well made, and uniformly proportioned: they are rarely brought into use, but where a horse is lower before than behind; and are in so much disrepute with amateurs and connoisseurs, that a real sportsman would

sooner part from his horse than to be seen to ride with a crupper.

CUB. A fox of the first year.

CURB is a callous enlargement, approaching ossification, and is situate at the lower junction of the bones, at the hind part of the hock, originally attended with stiffness, and lastly with lameness and pain. Curbs are evidently produced by kicks, blows, sudden turns or twists, riding too hard (or drawing too much weight) up hill: they should be attended to on their first appearance, when they soon submit to the usual modes adopted for extirpation. Mild blistering frequently succeeds, particularly where the operation is twice performed; but when the case is of long standing, a few slight feather strokes with the firing-iron may be necessary to confirm the cure.

CURB-CHAIN. See BIT.

CURRY-COMB, a well-known stable utensil, in constant use for the cleaning of horses. They are much more applicable to post and draft horses, than to horses of superior description, the fineness of whose coats, and the tenderness of whose skins, occasion much uneasiness to them

during the prickly persecution, and to whom good, sweet, clean straw-bands are greatly preferable; it being matter of fair doubt, whether more horses are not lamed in the stable under the dancing ceremony of the curry-comb, than by accidents upon the road, or strong exertions in the field.

CUTTING IN ACTION, in the manege called interfering, is lacerating the round inside projecting part of the fetlock joint, with the edge of the shoe, upon the foot of the opposite leg. This arises much more frequently from the indifference or neglect in the owner, than from any imperfection or defect of the horse: more horses cut from being broke and put into work too young, rode too long journies in a day, or over-worked when weary, than from any cause whatever. Some horses, it is true, cut from their formation, particularly those narrow in the chest.—Carriage horses, too, very frequently cut behind; but this must in a great measure be occasioned by the projecting parts and cavities in the pavement, for all which the surest footed horse existing cannot be prepared.

## D

DACE, or DARE, is gregarious, is a great breeder, very lively, and during summer is fond of playing near the surface. Its head is small, the irides of a pale yellow, the body long and slender; its scales are smaller than those of the roach, and it is upon the whole a handsomer fish: the back is varied with dusky, and a cast of yellowish green; the sides and belly silvery; the ventral, anal, and caudal fins are sometimes of a pale red hue; the tail is very much forked. The dace is seldom above ten inches long; although, in a list of fish sold in the London markets, with the greatest weight of each, communicated to Mr. Pennant, there is an account of one that weighed a pound and half; and, according to Linnæus, it grows to a foot and a half in length.

The haunts of dace are deep water near piles of bridges, where the stream is gentle, over gravelly, sandy, and clayey bottoms; deep holes that are shaded, water lily leaves, and under the foam caused by an eddy; in the warm months they are to be found in shoals on the shallows near to streams: dace spawn in March, are in season about three weeks after; they improve and are good about Michaelmas, but are best in February, and are said in that month, when just taken, scotched and broiled, to be more palatable than a fresh herring.

This is a fish affording great sport to the angler; indeed, more pleasure than profit, for the flesh is insipid, and full of bones. The baits for dace are the red-worm, brandling, gilt-tail, cow-dung and

## D A C E

earth-bob, and indeed any worm bred on trees or bushes, that is not too big for his mouth, and almost every kind of fly and caterpillar. Flesh flies upon the surface with the hook put into the back between the wings, the line from the middle downwards of single hairs, and a trifle longer than the rod, which ought to be eighteen feet at least, and as light as possible; the flies can be kept in a phial; fix three very small hooks upon single hair links, not above four inches long to the line, and in a summer's evening, at the smoothest part of the end of a mill stream, from seven or eight, and so long as light continues, the dace will yield diversion. In the same manner, they will rise in the morning at the ant-fly, if used at the foot of a current or mill stream, or on a scour before the sun comes on the water.

After rains, when the river is nearly level with its banks, use the caterpillar fly or a small red palmer and a yellow gentle, (the yellow the better;) run the hook through its skin, and draw it up to the tail of the fly, then whip on the surface, the dace will rise freely.

Another way to take this fish from the middle of April until the beginning of October, is by artificial fly-fishing with a long line, the fly generally either black, brown, or red, made very small, on a hook No. 8 or 9. The three may be on the line together, about a yard asunder, letting the black one be the lower fly, and that alone have a gentle at the end of it, and the other two to be the drop flies; by this mode many dozens may be taken in the course of a morning or afternoon; when they are on the fords, and the weather is favourable, particularly in rivers where the tide flows a moderate height, (as for instance, in the Thames, between Kew and Richmond bridges) for every tide is a kind of fresh water to the fish, and, as it clears off, they will take astonishingly. Their chief biting times are, hot weather, early or late; in cold, the middle; and in mild cloudy weather, the whole of the day; but after a hot, bright sun, they will take the above flies in the clearest water, from a little before sun-set, until dark. Above Richmond, when the weeds begin to rot, a grasshopper with the first joint of his legs pinched off, and the hook put in at the head and brought out at the tail, and used as an artificial fly, does great execution in a warm day upon the shallows; this fishing can only be done in a boat, which is to drive down with the current (having a heavy stone, by way of anchor, fastened to a rope five or six yards long, at the head of the punt or wherry): when come to a likely spot, drop the stone, and, standing in the stern, throw right down the stream, and then to the right and left; after trying about a quarter-of-an-hour in a place, weigh anchor, and proceed in the same manner at the next probable haunt; use a common fly-line about ten yards long, and a strong single hair next the hook. It may be said there is less certainty of catching dace in this way, than with a float and ground-bait; but to those who are situated near the banks of the Thames, between Windsor and Isleworth, so as to take advantage of a still, warm, gloomy day, it will afford much more amusement than the ordinary method.

In angling for dace with maggots, the tackle cannot be too fine,

the float small, the hook No. 9, the shot a foot from it: by baiting the place with a few maggots before fishing, the diversion will be increased. If using gentles in an eddy between two mill-streams, and the water is only two or three feet deep, there will be greater chance of success than where it is deeper; use here a cork float, bait with three large gentles, and strike at the first nibble; if there are large dace in the mill-pool, they will resort to this eddy.

In bottom fishing for dace, let the ground-bait be bread, soaked an hour in water; put an equal quantity of bran, knead it to a tough consistence, and make it into balls, with a small pebble in the middle to sink them; throw these balls a little up the stream from the spot where it is proposed to angle, that the current may not drive them beyond the reach of the line. Fish for dace within three inches of the ground, especially where the ant fly is the bait under water. The compiler has caught dace of upwards of a pound weight, upon night lines, baited with a minnow for eels.

In the Mersey, near Warrington, a fish called the Graining is taken, which much resembles the dace, but is slenderer, and the back straighter; the usual length does not exceed eight inches. The colour of the back is silvery, with a blueish cast; the eyes, ventral and anal fins, are paler than those of the dace; but the pectoral fin is redder, and they are much better eating.

**DAISY-CUTTER.** A sporting term for horses that go so near the ground, that they frequently touch it with the tip of one toe or the other, and are constantly in danger of falling. A horse with broken knees may be considered of this description.

**DAKER HEN, LAND RAIL, OR CORN CRAKE.** The length of this bird is nine inches; the bill is one inch long, strong and thick, and of a greyish brown, formed exactly like that of the water hen, and makes a generical distinction: the eyes hazel; the feathers on the upper parts are of a rufous brown, each dashed down the middle with black; the under parts the same, but paler, and not spotted, and edged with pale rust colour; chin very pale: both wing coverts and quills are of a lightish chesnut; the fore parts of the neck and breast are of a pale ash colour; a streak of the same colour extends over each eye, from the bill to the side of the neck; the belly is of a yellowish white; the sides, thighs, and vent, are faintly marked with rusty-coloured streaks; the tail is short, and of a deep bay; the legs are of the colour of the bill. It is always found among the corn, grass, broom, and furze. The land rail quits this kingdom before winter, and repairs to other countries in search of food, which consists of worms, slugs, insects, and seeds of various kinds; but

the water rail endures our sharpest seasons.

The corn crake is the harbinger of summer, and begins to be heard about the middle of May, and continues its note during the breeding season; it then migrates.

In meadows, from the time the grass is grown, until cut, there issues from the thickest part of the herbage a sound, expressing the word *crek, crek, crek*, and which is a noise much like that made by stripping forcibly the teeth of a large comb under the fingers: as we approach, the sound retires, and is heard fifty paces off: it is the land rail that emits this cry, and begins to be heard about the second week in May. The land rail (says Mr. Penant) lays from twelve to twenty eggs of a dull white, marked with a few yellow spots; but, according to Latham and Buffon, the number of eggs does not exceed twelve, which are larger than those of the quail, and more coloured; are an inch and a half in length, and not unlike those of the missel thrush, being of a reddish cinereous white, marked with ferruginous blotches, with a few indistinct ones of a pale reddish ash colour: the nest is negligently constructed with a little moss, or dry grass, and placed usually in some hollow of the turf where the grass is thickest. The young crakes are covered with a black down, and run as soon as they burst the

shell, following their mothers, but quit not the meadow till the scythe sweeps away their habitation. The late hatches are plundered by the mower; all the early broods then shelter themselves amongst buck-wheat, oats, very frequently in clover grass, and in waste grounds overspread with broom, where in summer they are often found: a few return again to the meadows at the end of that season.

It is easily known when a dog scents a land rail, from his keen search, and the obstinacy with which the bird persists in keeping the ground, insomuch that it may be sometimes caught by the hand; it often stops short and squats; the dog, pushing eagerly forward, overshoots the spot, and loses the trace; and the rail, it is said, profits by his blunder, and retraces its path; nor does it spring till driven to the last extremity, when it flies heavily, and generally with its legs hanging down, but never far at a flight: when it alights, it runs off, and before the sportsman has reached the place, the bird is at a considerable distance; nor is it sprung a second time but with great difficulty. The fleetness of its feet compensates for the tardiness of its wings; all its excursions, windings, and doublings in the fields and meadows, are performed by running. When upon wing, if it flies to a hedge, the sportsman is recommended to look upon the boughs, as it will perch and sit till he almost touches it, and frequently, by that means, eludes all pursuit.

Corn crakes are plentiful in some parts of these realms; in Ireland, particularly so. They are in the greatest plenty in the Isle of Anglesea, where they appear about the third week in April, supposed to come there from Ireland: at their first arrival, it is common to shoot seven or eight in a morning. They abound in the county of Caithness, in Scotland, and are found in most of the Hebrides, and the Orkneys. Few places in England are destitute of them in summer, but they are nowhere what may be called common. It is observed, wherever quails are in plenty, the crake abounds: on their first appearance in England, they are so lean as to weigh only four ounces, but before their departure have been known to exceed eight, and are very fat: their flesh is reckoned an exquisite morsel.

Buffon states, that when the land rail returns to other countries, the flight commences during the night, and, aided by a favourable wind, it attempts the passage of the Mediterranean, where, no doubt,

many perish, as it is remarked that their numbers decrease upon their return; that migrations of this bird extend more to the north than the south, and, notwithstanding the slowness of its flight, it penetrates into Poland, Sweden, Denmark, and even Norway. To the northern countries, he conceives, the land rail repairs, as much for cool situations, as to obtain its proper food; for although it eats the seeds of broom, trefoil, groundsel, and fattens in a cage on millet and grain; and when grown up, every sort of aliment suits it; yet it prefers insects, slugs, and worms; and these, which are necessary for its young, can be found only in shady, wet grounds: the humidity of those of Ireland is also congenial to its nature.

DAMASCUS ARABIAN (sire of Signal,) was a black-brown horse, and foaled in 1754. He arrived in England in September, 1760; and in 1761, 1762, and 1763, he covered none but thorough-bred mares, at Mr. William Coates's, at Smeaton, near North-Allerton, Yorkshire, at 5gs. and 5s.; in 1764, at Mr. Samuel Tate's, at Mickleham, near Leatherhead, Surrey; in 1765, at Mr. Coates's, Smeaton; in 1766, at Mr. John Tuting's, at Newmarket, at 1 guinea and 2s. 6d. (none of his get having started); at the same place, in 1767, (on account of Signal's superior running,) he was again advanced to 5gs. and 5s.; in 1768 and 1769, at the same price; in 1770, at 5gs. and 10s. 6d.; in 1771, at Wickham, near Witham, Essex, (same place as Captain,) at 5gs. and 5s.; in 1772 and 1773, at the same place, at 10gs. and 5s. The following is copied from the advertisement: "He was generally known to be of the purest Arabian breed, in that country, without any mixture of the Turcoman or Barb;—a horse of bone and substance; 14 hands half-an-inch high, and upwards, which size very few Arabians ever exceed. He was bred by the Arab, who was shieck or chief of Acria, noted for his breed of horses, and presented, when a foal, to the bashaw of Damascus, and given by him to a rich Turkey merchant at Aleppo, with whom the bashaw had great dealings in money affairs. He was bought there, at two years old, by an English gentleman, in whose possession he continued till his arrival in England. This account may be seen, certified on stamp paper, at Smeaton," &c. He was sire of Mr. Vernon's Flush, Mr. March's Mungo and Trump, Sir F. Evelyn's Atom, Mr. Strode's Little Joe, Mr. Burlton's Mufti and Pigmy,

Mr. Pleasant's Magpie, &c. He got the dam of Mr. Wentworth's Merry Wakefield, (afterwards Mr. W. Wilson's Menelaus) which dam was also the dam of the Ancaster Mare, that bred Mr. Fenton's Allegro, Dapple, Miss Grimstone, &c.

**DAPPLE.** Horses are so called who have partial variegated hues in the coat of different sizes, constituting small circles, both lighter and darker than the general colour of the horse. Such are said to be dappled; hence we have dapple bays, dapple greys, and sometimes dapple blacks.

**DARLEY ARABIAN** (sire of Childers) was the property of Mr. Darley, of Buttercramb, near York. A brother of that gentleman being an agent in merchandise abroad, became a member of a hunting club, by which means he acquired interest to procure the said Arabian for a moderate sum, and which he sent over to England as a present to his brother. He also got Almanzor, a very fleet horse; the Duke of Somerset's White-legs, own brother to Almanzor, and thought to be as good, but meeting with an accident, he never ran in public; Cupid and Brisk, good horses; Dædalus, a very fleet horse; Skipjack, Manica, Aleppo, Brisk, Bully-rock, Whistlejacket, and Dart, good plate horses, though out of indifferent mares; and Lord Tracey's Whimsey, a good plate mare. He covered only a few mares besides Mr. Darley's.

**DEBILITY.** A state of weakness, emaciation, and inertness of the animal powers. It may be either general or local. In the human subject, debility is a fertile source of diseases, chiefly of the chronic kind. So it is also in brutes, to a certain degree, though their diseases are generally simple, and apt to proceed to a speedy termination. The diseases of debility in the horse are, dropsy, grease, asthma, palsy, &c.

**DECEMBER.** Grouse-shooting terminates on the 10th of this month. Indeed, these birds become very difficult of approach at a much earlier period; and, after the middle of September, are sufficiently wild as to be approached only by stratagem. When snow has covered the mountains, grouse may be observed in packs, sitting upon it, and brooding, as it were, upon the miserable prospect before them. At such times, they may be approached, by the shooter putting on a white frock over his clothes, so as to resemble in some degree the colour of the

snow by which he is surrounded. This is practised by poachers, who are generally found numerous enough on most, if not all, the grouse mountains in England.

Notwithstanding the termination of the superlative diversion of grouse-shooting, December may be considered as the zenith of the sporting season. Partridges have become wild, it is true; but cover shooting may be enjoyed in perfection. This is the season of the pheasant and the woodcock, to say nothing of snipe;—for wild-fowl shooting, if it be allowable to class this chilly, shivering business, amongst the list of legitimate field sports.

Coursing can be enjoyed in the utmost perfection, unless prevented by frost or snow, or both. Hares run well at this period.

The preceding remarks are equally applicable to hare-hunting.

December is admirably calculated for the pursuit of the fox. At this period foxes run well; and a good scenting day will frequently occur during this month. A good fox and a good scent cannot fail to produce the perfection of this doubly delightful, this animating and princely, diversion. Fox-hunting leaves all other field sports at an immeasurable distance.

**DECOCTION.** Any thing boiled. By this process, the medicinal properties of roots, barks, &c. are communicated to water. The most common way is to boil the ingredients till the water is half consumed, the liquor (which, properly speaking, is the decoction) being afterwards strained off.

**DECOY.** A decoy is generally situated in a marsh, so as to be surrounded with wood or reeds, and, if possible, both, the better to keep the pond quiet, and that the repose of the fowl may not be interrupted; for the greatest parts of the animal world pass their lives in a state between sleep and inactive reverie, except when they are excited by the call of hunger. In this pond the birds sleep all day; so soon as the evening sets in, the decoy rises, (as it is termed,) and the wild fowl feed during the night. If the evening is still, the noise of their wings, during their flight, is heard at a great distance, and is a pleasing, although rather a melancholy, sound. In Somersetshire, this rising of the decoy in the eve is called rodding. The decoy ducks (which are either bred in the pond-yard, or in the marshes adjacent; and who, although they fly abroad, regularly return for food to the pond, and are mixed with tame ones, which never

quit the pond, and are taught for this purpose) are fed with hempseed, oats, and buckwheat, of which it will take, for the use of a pond for a year, about eight quarters of oats, one of hempseed, and one of buckwheat. The other expenses are—a man to constantly attend the decoy; every four years the poles and nets will be new, as in the intervening years they will be replaced; some at one time, some at another, so as to be all renewed in the above period. Reeds for repairing screens, Dutch turf, rent, decoy birds, and many *et ceteras*, are also to be included; and the repayment all depends upon the haunt of fowl which take to the pond.

In working, the hempseed is thrown over the skreens in small quantities, to allure the fowl forward into the pipes, of which there are several, leading up a narrow ditch, that closes at last with a funnel net. Over these pipes, which grow narrower from the first entrance, is a continued arch of netting suspended on hoops. It is necessary to have a pipe for almost every wind that can blow, as upon this circumstance it depends which pipe the fowl will take to; and the decoy man always keeps to leeward of the wild fowl, that his effluvium should not reach them; and this he likewise takes a further care to prevent, by keeping a piece of Dutch turf burning in his mouth or hand: for such is the acute sense of smelling which wild fowl possess, that, should the pond be full of fowl, if they scented a man not a bird would remain in it a moment. Along each pipe are placed reed skreens at certain intervals, which protect the decoy man from being seen, until he pleases to show himself, or the birds are passed up the pipe, to which they are led by the trained birds, who know the whistle of the decoy man, or are enticed by the hempseed. A dog, which is generally preferred to be of a red colour, is sometimes used, who is taught to play backwards and forwards, between the skreens, at the direction of his master; the fowl, roused by this new object, advance towards it, whilst the dog is playing still nearer to the narrow end of the pipes, until at last the decoy man appears from behind the skreens; and the wild fowl, not daring to pass by him, and unable to escape upwards on account of the net covering upon the hoops, press forward to the end of the funnel-net, which terminates upon the land, where a person is ready to receive them and break their necks; in doing of which there is much dexterity. The

trained birds return back past the decoy man into the pond again, until a repetition of their services is required. A side wind is the best to work the birds.

The general season for catching is from the latter end of October until February. The taking of them earlier is prohibited by the Act 10 Geo. II. c. 32, which forbids it from June 1 to October 1, under a penalty of five shillings for each bird destroyed within that space.

It was customary formerly to have in the fens an annual driving of the young ducks before they took wing. Numbers of people assembled, who beat a vast tract, and forced the birds into a net placed at the spot where the sport was to terminate. A hundred and fifty dozen have been taken at once; but this practice being supposed detrimental, has been abolished by Act of Parliament.

At Spalding, a record of this driving of the old birds, when unable to fly, states, “that at the ducking on Thursday last were taken up one hundred and seventy-four dozen of mallards or drakes moulting; and on Monday forty-six dozen and a half; in all, two thousand six hundred and forty-six mallards.” The above account certainly proves the necessity of parliamentary interference to prevent such slaughter, at a time, too, when the birds must be sickly and unwholesome.

A decoy in some seasons is astonishingly lucrative; in 1795, the Tillingham decoy, in Essex, at that time in the occupation of Mr. Mascall, netted, after every expense, upwards of eight hundred pounds, and the only birds taken were duck and mallard.

In 1799, ten thousand head of wigeon, teal, and wild ducks, were caught in a decoy of the Rev. Bate Dudley, in Essex.

The tricks which the decoy men employ to destroy the haunt of the birds in each other's ponds are various, and as well calculated to produce the mischievous effects they intend, as can well be devised; such as putting a slightly-wounded bird or two into the pond—not a bird will *pipe* until the *stricken deer* is removed; and the natural shyness of the bird is so awakened by the pain of his wounds, that it is sometimes the labour of two or three days to secure him and restore tranquillity. A second manœuvre is, thrusting a feather through the nostrils of a wild fowl, and launching it into the decoy: here again not a fowl can be caught until this deformed stranger is got rid of. A third, and perhaps the most decisive, is, starting

train oil into the brook or rill which supplies the pond at some distance from it; some portion of this will be carried by the current into the decoy; and in an instant the fowl, however numerous, quit, and

will not resume their haunt until every taint is removed.

DEER. See FALLOW DEER, ROE-BUCK, STAG, &c.

**DEER-STEALERS** are those nocturnal depredators who, setting at defiance all laws, all possession of property, and the protectors of it, disguise themselves, and, under cover of the night, attack, seize, kill, and carry away, from the best fenced parks, bucks or does (according to the season) with the greatest impunity. Their mainspring of action is a dog of the cur kind, called "a coney-cut lurcher:" this is a breed peculiar to itself, and those who use it; being a light sort of brindled wirey-haired mongrel, with a natural stump tail, having the appearance of a bastard greyhound. They are exceedingly fleet and lasting, run mute (by either nose or sight); and are so well trained for the purpose to which they are solely appropriated, that they are equally expert in picking up a hare, or pulling down a buck. After having executed their office, though in the darkest night, they will soon recover their master by scent, and lead him to the game so pulled down, which is repeated till a sufficiency is obtained for that journey; the business having been so systematically conducted, by the various neighbouring emissaries and associates concerned, that horses and carts were employed, and a regular routine of robbery carried on, by periodical and alternate depredations upon most of the parks within fifty or sixty miles of the metropolis. Many living in a line of respectability in other respects, were publicly known to be employed in the nefarious practice without fear of detection; for no informer could come forward, without a very great probability of destruction to his person or property, from some of the many confederates concerned.

These offences, so long thought but little of, became at length enormities of such magnitude, that the legislature discovered a necessity for the introduction of new and more severe pains and penalties. A variety of statutes were enacted in the reigns of former sovereigns for the punishment of such offenders, which are now fully concentrated in the Acts of Parliament passed in the reign of George III.

By these statutes, if any person shall hunt, or take in a snare, kill or wound, any red or fallow deer, in any forest, chase, &c. whether inclosed or not, or in any inclosed park, paddock, &c. or be aiding in such offence; they shall forfeit twenty pounds for the first offence; and also thirty pounds for each deer wounded, killed, or taken. A game-keeper, guilty of either, to forfeit double. For a second offence, the offenders may be transported for seven years.

Justices may grant warrants to search for heads, skins, &c. of stolen deer, and for toils, snares, &c. and persons having such in their possession, to forfeit from ten to thirty pounds, at the discretion of the justices. Persons unlawfully setting nets or snares, to forfeit, for the first offence, from five to ten pounds; and for every other

## DEER-STEALING

offence, from ten to twenty pounds. Persons pulling down pales or fences of any forest, chase, park, paddock, wood, &c. subject to the penalties annexed to the first offence for killing deer. Dogs, guns, and engines, may be seized by the park-keepers; and persons resisting shall be transported for seven years. Penalties may be levied by distress; in default of which, offenders to be committed for twelve months.

Persons disguised, and in arms, appearing in any forest, park, paddock, &c. and killing red or fallow deer, deemed felons without benefit of clergy. Prosecutions limited to twelve months from the time of the offence committed. Destroying gorse, furze, and fern, in forests and chases, being the covert for deer, is liable to a penalty from forty shillings to five pounds; to be levied by distress; and if no distress, the offender to be committed to the county gaol, for a time not greater than three months, nor less than one.

Deer-stealing, formerly so much practised, has of course ceased, as the forests are for the most part enclosed, and deer no longer to be found in a state of freedom, except some few which may perhaps still be found in Devonshire. Deer-stealing was much in vogue in the days of Shakspeare; and to the dread of punishment for this offence we are indebted for the works of our immortal bard. Shakspeare had, in early life, fallen into bad company, amongst whom were some that followed deer-stealing, and with whom he was engaged more than once in robbing Charlecote Park, near Stratford-on-Avon, belonging to Sir Thomas Lucy: for this he was prosecuted, and, in order to be revenged, wrote a ballad upon that gentleman; and although this, perhaps the first essay of Shakspeare's poetry, be lost, it is said to have been so very severe, that it incensed the person who had already commenced a criminal prosecution against him to that degree, that he was obliged to leave his business and family in Warwickshire, and shelter himself in London; where his first employment was, to wait at the door of the play-house, and hold the horses of those who had no servants; for in the time of Elizabeth, there being no hackney coaches, it was a common practice to go to the theatre on horseback. In this office, Shakspeare's attention became so remarkable, that he was always called for, and scarcely any other person trusted with a horse while he could be had. He was afterwards received into the company of players then in being, perhaps rather as an attendant or servant, than as a performer. His admirable wit soon distinguished him, if not as an actor, yet as a most excellent writer. In his *Merry Wives of Windsor*, Justice Shallow is introduced in remembrance of his Warwickshire prosecutor.

Gilpin, in speaking of the New Forest, says, "I had some occasional discourse with a forest borderer, who had formerly been a noted deer-stealer. He had often, like the deer-stealer in the play,

Struck a doe,  
And borne it cleanly by the keeper's nose:

indeed, he had been at the head of his profession; and, during a reign

of five years, assured me he had killed, on an average, not fewer than a hundred bucks a year. At length, he was obliged to abscond; but, composing his affairs, he abjured the trade, and would speak of his former arts without reserve. He has more than once confessed the sins of his youth to me; from which an idea may be formed of the mystery of deer-stealing in its highest perfection. In his excursions in the forest, he carried with him a gun, which unscrewed into three parts, and which he could easily conceal in the lining of his coat. Thus armed, he would drink with the under keepers without suspicion, and, when he knew them engaged, would securely take his stand in some distant part, and mark his buck. When he had killed him, he would draw him aside into the bushes, and spend the remaining part of the day in a neighbouring tree, that he might be sure no spies were in the way: at night, he secreted his plunder. He had boarded off a part of his cottage (forming a rough door into it, like the rest of the partition, stuck full of false nail-heads) with such artifice, that the keepers, on an information, have searched his house again and again, and have gone off satisfied with his innocence, though his secret larder at that very time, perhaps, contained a brace of bucks. He had always a quick market for his venison; for the country was as ready to purchase as these fellows were to procure it. It is a forest adage of ancient date—*Non est inquirendum unde venit venison.*

A peer suffered for a murder committed by a gang of deer-stealers whom he had thoughtlessly accompanied. This occurrence took place in the year 1542, when Lord Dacres, in a frolic, went with the gang just mentioned to steal deer from the park of Sir Nicholas Pelham. The park-keeper was killed; and as the noble lord was taken along with the rest, and accused of the murder, he was persuaded to plead guilty, under the full persuasion that no difficulty would be experienced in procuring a pardon for a person of his exalted rank. He was, however, executed, though it was ascertained that he was not present when the murder was committed.

DEFAULT; a term in hunting, which custom has reduced to an abbreviation, and it is in general termed fault. The hounds, during a chase of any kind, when losing the scent, throwing up their noses, seeming at a loss, and dashing different ways, in anxious and earnest hope of recovery, are then said to be at "fault."—This is the very moment when the judgment of the huntsman is most required, and the soonest to be observed. Different opinions have been formed, and decisions made, respecting the proper mode of proceeding at so critical a juncture, whether to try forward, or to try back: here a great deal depends upon the game you are hunting of, and the country you are hunting in, which circumstances at the time can only determine. However opi-

nions may vary upon some particular points, all seem to coincide upon others; that the ground should, for fox, be made good forward, previous to trying back; that a general silence should prevail, and not an unnecessary aspiration be heard, that can tend to attract the attention of a single hound from the earnest endeavours he is so busily engaged in; by which means nineteen faults are hit off out of twenty, without greater delay, suspense, or disappointment.

If hounds, in pursuit of fox, throw up on a fallow or highway, they cannot be got forward too soon; certain it is the fox has not stopt there: not so with the hare, who is likely to have thrown herself out by the side of one, or squatted in a land (or furrow) of the other. Faults

with the former, are much more easily and expeditiously hit off than with the latter, with whom they are sometimes tediously incessant, particularly with a young or hard hunted hare: it should, therefore, be a fixed rule, never to abandon a fault, if possible, without recovery; it being as likely, at least, to bring the lost hare to a view, as to find a fresh one.

—See HUNTING.

DEFECTS in horses differ very materially from what are termed blemishes, (which see:) the latter are always considered conspicuous, and easily observed by the eye of experience and judicious inspection. A horse may have defects not so readily to be perceived, and consequently remain a longer or shorter period before they are discovered: he may prove incorrigibly restive, and not happen to display it in a new situation for days or weeks; he may be a seasoned and invincible crib biter; he may be vicious to dress; a kicker in the night; doubtful in the eyes; awkward in action; troublesome to saddle, and, when saddled, more troublesome to ride. Though these are defects, yet the dealer (proceeding upon the purest principles of integrity) conceives them professional privileges of secrecy, which he is not bound in honour to disclose; affecting to believe, they are totally abstracted from every idea conveyed in the declaration and warranty of being “perfectly sound.”

That this matter, however, may be the better and more universally understood, it cannot be inapplicable to introduce the opinion which the late Lord Mansfield held publicly in the Court of King's Bench; “that a restive horse was tantamount to an unsound one; and upon this principle, that if the subject so purchased was evidently restive, and would not, or could not, by fair means, be prevailed upon to go where he was required, he was equally useless with an invalid whose lameness or infirmity prevented him from executing the purposes for which he was purchased.” From such authority (founded upon the basis of equity) there can be but little, if any, doubt, an action brought for the recovery of money paid for a restive horse, such horse having been “warranted sound,” would obtain a verdict.—As, however, the proverbial uncertainty of the law, the confusion of witnesses, and the caprice of a sleepy jury, are very slender reliances for the man of prudence and honour, who wishes “to do unto others as he would be done unto,” the

safest method for every purchaser is to take (from the gentleman as well as a dealer) a proper receipt, upon payment of the money, that such horse or mare is warranted sound and free from vice; by which litigation and law-suits may be prevented.

DELPINI, originally called “Hackwood,” was bred by the late Duke of Bolton; foaled in 1781; and got by High-flyer out of Countess, who was got by Blank. Delpini proved himself a very capital racer, beating most of the best horses of his year at all ages. He has also acquired some celebrity as a stallion, being the sire of Kilton, Prior, Skelton, Miss Ann, Tiptoe, Abram Wood, Cardinal, Clymene, Dido, Golden Locks, Dapple, Flutter, Little Scot, Miss Beverly, Nixon, Opposition, Timothy, Agnes, Blue Beard, Camperdown, Duchess, Hopwell, L'Abbé, Laborie, Patch, Stourton, Symmetry, Baron Nile, Maid of the Mill, Slap-bang, Sabella, and many others, all winners.

DEMI-AIR, OR DEMI-VOLTE, in the manege, one of the seven artificial motions of a horse; being an air in which his fore parts are more raised than in *terra a terra*; but the motion of the horse's legs is more quick in the latter than in the demi-volte.

DENTITION. Teething.

DESICCATIVE (from *desicco*, to draw away, or dry up), medicines used to dry up, or skin over, old sores.

DETERGENTS, a class of medicines supposed to cleanse and fill up with new flesh all ulcerations and foulnesses. Most applications which stimulate moderately are detergent: for instance, honey, lime-water, ægyptiacum, &c.

DIABETES, OR PROFUSE STALING. This disease may be known by an immoderate discharge of pale urine, accompanied with coldness of the skin, staring of the hair, weak pulse, loss of appetite, constant thirst, and general debility.

The causes of the diabetes are those in general which dispose an animal to hydropic affections. Mr. Denny attributes it, in many instances, to bad forage, particularly of oats damaged by salt water.

This, he says, is so very frequent a disease in regiments of cavalry, that he has seen “more than a hundred horses labouring under it at one time.” In these instances, however, the disease can hardly be supposed to have arisen from general debility or any chronic affection, since

we are told, that, though many remedies have been proposed for the cure of this disease, it will always be sufficient to observe the following treatment.

“ On the first discovery of the disease give the following ball morning and night:

Alum in powder, 2 drachms.

Armenian bole, half an oz.

Peruvian bark in powder, half oz.

Ginger in powder, 2 drs.

Treacle, enough to make a ball.

“ Mashes may be given two or three times daily, to keep the bowels open, and a moderate quantity of lime-water should be administered for drink. Walking exercise should be allowed, and also warm clothing. The skin of the animal should be well rubbed, and particularly the legs.

“ When the disease is removed, the horse's food should be of the best quality.”

If the chronic diabetes of the horse yield to this treatment, we certainly have no reason to consider it a formidable malady. That veteran of his time, Gibson, however, represents the “true diabetes,” as a disease difficult of cure, and for this simple and convincing reason, that it is the result of debility from “long-continued sickness, old surfeits, or the effect of hard riding or hard labour,” accompanied with poor diet.

DIAMOND was esteemed for some years the speediest and best bottomed horse in the kingdom. He was foaled in 1792; bred by Mr. Dawson; got by High-flyer out of the dam of Sparkler, and was own brother to Screveton. At three years old, he repeatedly ran in handsome with some of the first horses, and was within a length of winning the Derby at Epsom when twelve started, but did no more than receive 50 guineas forfeit from Lark at the second Newmarket meeting of the year 1795. First spring meeting, 1796, he won the Jockey Stakes of 100 guineas each, six subscribers. In the July meeting of the same year he walked over for a sweepstakes of 200 guineas each, seven subscribers. In 1797, when Mr. Cookson's, he won the King's hundred at Newcastle, and a £50 plate the next day at the same place; £50 at York; the 50 guineas for all ages at Newmarket, beating Yeoman, Play or Pay, Aimator, and others. The next day he won the King's hundred guineas, beating the famous Hermione and Vixen. In 1798 he beat Moorcock, over the Beacon Course, for 200 guineas, Monday in the Craven meeting. First spring meeting he won a sweepstakes of 100 guineas each, twelve

subscribers. Second meeting, received a compromise from Lord Clermont's Spoliator. At Oxford he won the gold cup of 100 guineas value, with 50 guineas in specie, beating Stickler, Johnny, Oatlands, and Whip; all excellent runners. The King's hundred at Nottingham; the King's hundred at York; and beat Sir H. T. Vane's Shuttle, four miles over Doncaster for 1000 guineas: the odds eleven to eight upon Shuttle. In 1799 he was beat half a length, the great match, by Hambletonian, over the Beacon Course at Newmarket, for 3000 guineas; the odds five to four upon Hambletonian. More money was sported upon this match, and more company went from the metropolis to see it decided, than ever was known upon any other race in the kingdom.—The next day he won the first class of the Oatlands stakes 50 guineas each (ten subscribers) beating eight of the best horses of the year. First spring meeting he won the King's hundred, beating Grey Pilot, Lounger, and St. George. Second meeting, won the Jockey Club plate, and 50 guineas, beating Stamford and Lounger. In 1800, first spring meeting, he won a subscription £50, beating Stamford, the famous Coriander, and Wrangler. First October meeting he received 250 guineas forfeit from Warter. Second October meeting he beat Hippona over the Beacon Course, 200 guineas. Here ended his career by the death of Mr. Cookson; after which he was sold, and taken to Ireland; where, being engaged by his owner in a match of much magnitude, he was lamed by over-training.

DIAPHRAGM, vulgarly called the midriff or skirt, a muscular substance in a horse, bullock, or other quadruped, which divides the upper cavity, or chest, from the abdomen, or lower belly. It takes its origin from the loins, and is inserted into the lower part of the breast-bone, and the five inferior ribs, by which it makes several points. The middle is a flat tendinous substance, from whence the fleshy fibres begin, and are distributed like rays from a centre to its circumference. When this muscle acts alone, it contracts the breast, and pulls the ribs downwards, by which it assists the muscles of the lower belly in the expulsion of the fæces: but its chief office is in respiration, to which all the muscles of the breast, the intercostals, and those of the lower belly, are more or less subservient.

In all the actions of respiration or breathing, the muscles of the breast have

the greatest force in men: but in horses, and some other creatures of a prone position, it is evident the diaphragm has also a very great force, which seems to be plain in broken-winded horses; many of which have no other indication but that this is stretched or relaxed in a very extraordinary manner. In such cases, the membranous fibres are for the most part extremely thin, and the tendinous parts, towards their insertions into the ribs, very small and feeble, by which means it loses a great deal of that force and spring that is necessary to its action.

When a horse, or any other animal, receives the air into his lungs, the breast and ribs are distended, which is done by the dilatations of the pectoral muscles, by the extension of the intercostals, viz. the muscles of the ribs, and by the diaphragm, which at that time is drawn out and expanded to its full dimensions, or in proportion to the quantity of air received into the lungs. The muscles of the abdomen act also by their connection with those of the breast and ribs, which we perceive more plainly in quadrupeds than in men, where the lungs are upon a level with the parts of the lower belly. On the other hand, when the air passes out of the lungs, the muscles that draw in or compress the breast, and those that compress the ribs, act alternately with the extensors of the breast and ribs. The diaphragm, which is stretched out in time of inspiration, contracts, and in its centre rises upwards like the bottom of a dish.

DIARRHŒA, otherwise called LAX, or SCOURING. This disease, in the horse, is distinguished by a frequent discharge of fæces, accompanied with pain, restlessness, and loss of appetite. After the second day the discharge is chiefly mucous, or mixed with small and hard lumps of fæces, covered with an oily matter. Mr. Denny observes, that when the disease has been too long neglected, and that the discharge becomes involuntary, accompanied with coldness of the legs, a fatal termination will generally ensue.

The disease, he says, may arise from debility, mucus irritating the intestines, violent exercise, drinking large quantities of cold water when the body is heated, and, lastly, from worms.

Diarrhœa sometimes occurs after acute diseases, and in such instances frequently proves salutary; but in others, arising from various causes, it ought, if possible, to be removed by medicine. These vary, and require different modes of treatment.

1. A *critical diarrhœa* is accompanied with debility. Powerful astringents must be avoided, and such gently stimulating medicines only employed as will have a tonic effect in restoring the healthy functions of the intestines. To accomplish this end, Mr. Denny advises that the following ball should be given:

Calomel, 1 drachm.  
Aloes, 2 drs.  
Cinnamon, 2 drs.  
Ginger, 2 drs.

Treacle, enough to make a ball.

Twelve hours after, we are directed to give the following ball, and to repeat it morning and night:

Coriander seeds, half an oz.  
Caraway seeds, in powder, half oz.  
Ginger, 2 drs.  
Rhubarb 2 drs.  
Armenian bole, 2 drs.

Treacle, enough to make a ball.

The diet should consist of mash of oatmeal and bran, or malt, not made too moist: and a handful of bran may be boiled in the water intended for drink, which should be given sparingly.

2. In diarrhœa arising from violent exercise, or from drinking large quantities of water, Mr. Denny says the following methods may be employed. If the horse be valuable, let the following draught be given, and repeated six hours after, if needful.

Cinnamon 2 drs.  
Cloves 2 drs.  
Ginger in powder 2 drs.  
Brandy 4 oz.  
Tincture of opium 2 drs.  
Gruel, one pint. Mix them.

The horse's body should be well rubbed with flannel, and he should be kept warmly clothed.

An hour after the above mixture, a warm mash may be given. Plenty of good bedding should be allowed, and the stable kept quiet, to favour the animal's rest. If this treatment cannot be complied with, the following mixture may be given every three hours, until the symptoms are relieved.

Caraway seeds bruised 1 oz.  
Coriander seeds bruised 1 oz.  
Ginger in powder 2 drs.  
Gruel, two quarts.

Boil them for eight minutes; then strain, and add

Tincture of opium, 2 drs.

Mix them, and let the whole be given warm.

DIET, such select articles of food as,

when persevered in, are likely either to preserve health, or to assist the operation of medicine in the cure of a disease. Mr. Clark's account of the diet proper for sick horses affords us the following remarks.

He says, it may be observed, that, in some diseases, even of the inflammatory kind, some horses retain their appetite for food in a degree, whilst others, when very sick, refuse every kind of sustenance.—In the former case, it ought to be given in a small quantity at a time, and frequently repeated; it should be of the softest kind, scalded bran, boiled barley, malt, or dry bran, if the horse refuse soft food. When a horse refuses food of every kind, it is too common to force it upon him, by pouring wine sops, &c. down his throat, under the apprehension that the horse will die for want of nourishment.—This, however, is not the case: if the animal loaths food, it is a certain sign that he is disordered, and therefore cannot digest it; and the throwing or forcing it into the stomach will serve only to aggravate the disorder under which he labours, by increasing that oppression which already prevails. It is farther to be observed, that the stomach of a horse has not the faculty of vomiting, or even belching up wind by the mouth, which, in such cases, might give relief. If a horse will drink water freely, Mr. Clark considers that the best medicine in such a situation, as it dilutes the contents of the stomach, and thus affords an easier passage for them into the intestines. For these reasons, he insists, that no food whatever should be forced on sick horses; neither should they even be tempted with oats, or other relishing food, as it is by no means proper for them in such a situation, although they should seem disposed to take it, which they frequently will by way of change.

If, however, the existence of the animal, or his recovery, seem to be endangered by a continued rejection of food, it should be remembered that art furnishes us with another resource to support him, namely, by clysters. That nourishment may be conveyed to an animal body by this means, is well known: (see CLYSTER). After the intestines have been emptied of excrement, by clysters of warm water, or of very thin water-gruel, in which a handful of common salt, or a few ounces of Glauber's salt, have been dissolved, nourishing clysters, composed of two or three quarts of thick water-gruel, may then be injected, and repeated as often as

may be thought necessary. There is, in fact, no danger of a horse's suffering from the want of nourishment by the mouth in a fever; but there is great danger to be apprehended from its being forced on him, when the stomach cannot digest it. After the great intestines have been thoroughly emptied of the hardened excrements by clysters, the contents of the stomach will find an easy passage into the smaller ones. The horse then naturally craves fresh aliment; but, when this takes place, there will be danger in indulging him with too much at once; and this should by all means be guarded against.

DIGESTION, in the animal economy, is the dissolution or separation of the aliments into such minute parts as are fit to enter the lacteal vessels, and circulate with the mass of blood; or it is the simple breaking of the cohesion of all the little *moleculæ* which compose the substances men and animals feed upon.—Now the principal agents employed in this action are, first, the saliva, the juice of the glands in the stomach, and the liquors drank, whose chief property is to soften the aliment, as they are fluids which easily enter the pores of most bodies, and, swelling them, break their most intimate cohesions. And how prodigious a force fluids acting in such a manner have, may be learned from the force that water, with which a rope is wetted, has to raise a weight fastened to and sustained at one end of it; and this force is much augmented by the impetus which the heat of the stomach gives to the particles of the fluid: nor does this heat promote digestion only thus, but likewise by rarefying the air contained in the pores of the food, which helps to burst its parts asunder.—And, therefore, such liquors as are most fluid, or whose particles have the least viscosity, are most proper for digestion, because they can most easily insinuate themselves into the pores of the aliments; and, of all others, water, the almost universal beverage of created beings, seems to be the fittest for this use. Aromatic substances, and indeed the whole class of stimulants employed as medicine, seem to help digestion, as they excite the coats of the stomach to a stronger contraction; and, therefore, when they are duly diluted, they may not only be useful, but occasionally requisite. When the food is thus prepared, its parts are seen separated from one another, and mingled with the liquors in the stomach, from whence it is

propelled into the duodenum, where it mixes with the pancreatic juice and bile from the liver. The chyle is thence absorbed, and carried into the circulation by means of the lacteal vessels, whose extremities open into the intestinal canal for that purpose. Digestion is performed under different circumstances according to the peculiarity of structure of the digestive organs in different animals, and of the substances on which they are destined by nature to feed.

**DIGESTIVES**, are such unguents, balsams, or other particular preparations, as, being applied to wounds, tend to cleanse, fill them with healthy granulations, and promote the discharge of a laudable matter. Of this class are basilicon, and such other salves as contain the turpentine or stimulating gums. The following formulæ are given by Mr. Denny, a late veterinary writer.

**DIGESTIVE OINTMENT.**

Take of Olive oil, one pint.

Yellow wax, one pound.

Yellow resin, one pound.

Common turpentine, half a lb.

Melt the wax and resin with the oil over a slow fire; then take them off, add the turpentine, and strain the mixture while it remains hot.

**GREEN DIGESTIVE.**

Take of Digestive ointment, 8 oz.

Olive oil 3 oz.

Verdigrese powdered 1 oz.

Melt them together.

Many other recipes might be given, but these are as effectual as any.

**DIOMED** was in great repute as a racer, and afterwards as a stallion at ten guineas a mare. He was bred by Sir C. BUNBURY; got by Florizel; dam by Spectator, and grand-dam by Blank; was foaled in 1777, and proved himself an equal runner with the best horses of his time. As a stallion, he has propagated some of the finest stock in the kingdom. Diomed is the sire of Anthony, Charlotte, Grey Diomed, Lais, Mademoiselle, Playfellow, Quetlavaca, Sir Cecil, Whiskers, Montezuma, Glaucus, Speculator, Champion, Little Pickle, Michael, Monkey, Young Grey Diomed, Snip, Tom, Robin Grey, Dalham, Gautimozin, Habakkuk, Adela, Cædar, Switch, Greyhound, Laurentina, Poplar, Wrangler, and Egham; all considered *winners*; exclusive of many others who won matches and sweepstakes, (as colts and fillies) but were never named.

**DISEASE**, that state of an animal in which there is such an alteration of the

chemical properties of the fluids or solids, or of their organization, or of the action of the moving power, as to produce an inability or difficulty of performing the functions of the whole or any part of the system, or pain, or a preternatural evacuation. Diseases are either general, idiopathic or primary, local, sympathetic, or symptomatic; and it is necessary to a right treatment of the diseases of animals, that the veterinary practitioner should have clear ideas as to these points before he attempts to apply his remedies.

The general management of horses, when sick, is very judiciously treated of by Mr. Clark, of Edinburgh. He observes, that the diseases to which horses are liable have a great analogy to those of the human body: at the same time that they are almost as numerous.

He considers a question which naturally occurs, viz. how it happens that horses are so liable to such a numerous train of diseases more than other animals of the brute creation? The answer is found in their artificial state of existence: they are more domesticated than other animals, the dog only excepted; and even the latter is left more at liberty than the former. The horse, in his natural state, affords no instances of disease; neither is it found that horses are liable to diseases when left to run wild in different parts of Britain. Nay, it is likewise a fact, that young horses are exempt from disease while running at liberty in a country somewhat distant from towns or villages. They seem, even there, to enjoy a perfect state of health, till they are taken into stables, and come more immediately under the direction of man; it is then that this great change seems to take place in their constitutions. Hence it may be justly inferred, that their proneness to disease arises solely from the treatment they are subjected to, from the musty, close, hot, foul-aired, damp stables, &c. they are confined in; from a sort of food, not, strictly speaking, natural to them; from other errors in their diet, drink, &c.; from the want of free air and exercise, or from the excess of the latter; from the sudden transitions they are compelled to undergo, from heat to cold, and from cold to heat; from suffering them to drink cold water when over-heated; neglect of proper friction or dressing, &c. &c.

“On considering the variety of diseases to which horses are liable in a domesticated state,” says Mr. Clark, “it is surprising what affinity there is in the symptoms

attending each of them, with those which take place in the human body in the like situation; insomuch that, if the symptoms attending any one of the diseases to which horses are liable were faithfully related to a physician, although he never saw a sick horse, yet he could from thence name the disease under which the horse laboured at the time. From these, and a variety of other arguments which might be offered, it will be obvious, that the cure of the diseases in horses must depend upon the same principles as those of the human body, and that the prevention of diseases in the former must likewise depend on obviating the causes which dispose and render them liable to these diseases."

**DISTANCE.** A sporting term appertaining solely to the turf. It is a length of two hundred and forty yards (actual measurement) from the winning-post of every race-course in the kingdom; precisely at which spot is fixed a post corresponding with others, but having a gallery annexed capable of holding three or four persons, which is called the *distance-post*. In this gallery, as well as in the gallery of the winning-post, before the horses start each heat, is stationed a person holding a flag; during the time the horses are running, each flag is suspended from the front of the gallery to which it has been appropriated; but immediately upon the first horse passing the holder of the flag in the gallery of the winning-post, he strikes the flag; at the very moment of his doing which, the holder of the flag in the gallery of the distance post strikes his also, in confirmation that the heat is decided; and such horse or horses (running for the plate) as may not have passed the distance-post before the flag is struck, is then deemed a distanced horse, and disqualified from starting again for the same plate or prize. A horse running on the wrong side of a post, the rider not bringing his proper and full weight to scale after the heat, or dismounting without first riding his horse up to the side of the scale, and weighing, are also deemed distanced horses, and not permitted to start again.

**DISTEMPER,** a word used by the old writers synonymously with disease; but, with the moderns, rather confined to those morbid affections that are contagious.—It is often used vaguely to describe a sickness or indisposition the nature of which is not understood. Thus we hear of the "distemper" in cows, dogs, &c.—

Mr. Ryder, a late veterinary writer, has given this name to a contagious affection in the horse, which he describes in the following terms:

"In England," says he, "horses are extremely subject to receive injury from the sudden changes which take place in the temperature of the atmosphere, particularly during the spring and autumn quarters; the moisture of the air at these periods, combined with the heat, is very apt to produce inflammation of the mucous membranes, coughs, and sometimes inflammation of the lungs. When this inflammation and cough is attended with a discharge of matter from the nostrils, it constitutes a disease which is called the distemper, for which every farrier thinks that he has an infallible antidote; but is frequently found that a number of valuable horses fall victims to this disease, which we conceive may be owing to the error of treatment.

"The principal symptoms observable in the distemper are, first, a slight inflammation of the top of the throat, attended with a cough, which becomes more frequent and violent, particularly when the patient attempts to swallow his food, the action of the heart and arteries is increased, and the pulse is more quick and hard, with some degree of fever; the tongue is very hot and white, but not always dry, being sometimes covered with tough mucus; and, when difficulty of breathing is joined to these symptoms, we have great reason to apprehend that the lungs are affected.

"There is very little appearance of any enlargement of the external glands about the neck, or under the jaw, as in strangles; the inflammation being principally confined to the throat, windpipe, and adjacent parts, which appear much tumified and sore.

"Where no medicines have been given, or any operation used, this disease terminates by a critical purging, but more frequently by a large secretion of matter from the nostrils. The method of practice we have found most effectual for the cure of the distemper is as follows:

"Frequent bleeding in small quantities, about three pints at a time, and a hair bag, containing a large mash, nearly scalding hot, should be fastened on the head, and round the nostrils, so as the patient may inhale the whole of the hot steam; and the mash should be changed four or five times a-day. This will relax the inflammation of the throat, and pro-

mote a more free discharge of matter from the nostrils.

“If there be much fever, which is generally the case, half an ounce of nitre, dissolved in two quarts of water in which bran has been steeped, may be given, a little warm, at one time, or used as his ordinary drink. And if there be any difficulty in his breathing, the bleeding may be increased to three or four quarts the first time, and afterwards in small quantities, or as symptoms may direct.

“The horse should be moderately warm clothed, and should frequently be gently exercised; and if oats are given, they should be bruised, and steeped in hot water.

“In the place of hay, fresh grass, where it can be procured, will be found the best diet, as it has a tendency to keep the body cool, and gently open the intestines.”

**DIURETICS.** Under this head are included those medicines whose most remarkable properties appear in their increasing the discharge by urine, or which are said to remove obstructions in the urinary passages.

They are supposed to lubricate or soften the fibres which compose the urinary glands and canals, and, by their attenuating and detersive properties, rarefy and thin viscidous or thick humours, so as to render them capable of passing through these canals, which they could not do in a viscid state; but, whichever of these ways they operate, it is well known that they are of singular use in promoting the discharge by urine, by which diseases are not only frequently carried off, but actually cured with expedition; and, in many cases where purging medicines are prescribed, diuretics would be much more preferable, as they may be used with greater safety, more especially when it is considered that the chief effects of either of these prescriptions tend only to lessen the quantity of fluids in the body. Hence it will appear how salutary and beneficial medicines of this kind are to horses in a great variety of cases, but more particularly in those where any obstruction has taken place in the urinary vessels, attended with difficulty in staling—a complaint which horses are very subject to, owing to a variety of circumstances. From this consideration, it will likewise be obvious how necessary it is to allow horses, which are upon a journey, or travelling long stages, to stand still at times, in order to let them make water: from a neglect

of this kind, many horses are killed; for, when the bladder has been over full, and distended beyond its natural dimensions, it turns paralytic, and loses the power of contracting itself again for some time, so as to expel the urine immediately; hence dangerous symptoms ensue, which, if not speedily relieved, prove fatal. Besides, when the urine is too long retained in the bladder, it is not only re-absorbed or taken up again into the mass of fluids, but, by stagnating, it becomes thicker, the more watery parts being carried off first by absorption, the more gross and earthy parts remaining behind, and the tendency which these particles have to concrete may promote the formation of gravel, &c.

Diuretic medicines are most frequently administered in the form of balls; but, in some circumstances, they may be given in the form of powders in the food. Nitre is not only an alterative, but it acts as a powerful diuretic to horses, and, in some cases, may be given from one to four ounces a day, according as circumstances may require.

To coarse horses, or those of robust strong constitutions, from two to four ounces of yellow rosin in powder may be put into their food, and repeated for two or three times, at proper intervals, according as it is found to operate in cases of swelled legs, greasy heels, &c.; and it ought always to be observed, that, when diuretic medicines are given, the horse should be indulged with plenty of water to drink during the time they are operating.

The cases which require diuretic medicines, and which occur most frequently, are when any difficulty is observed in a horse's making water, or when liable to frequent attacks of the strangury, or suppression of urine, when the urine appears too thick, turbid, or discoloured, whether it be red, yellow, or black; when there are symptoms of any latent disorder, attended with a dulness or heaviness in the horse's looks, a staring dusty-like coat, local swellings on any part of the body, as on the belly, sheath, or legs; running sores about the latter, commonly called the grease, &c.; in cases where there are eruptions or pustules on the surface of the skin, or when the horse appears itchy, and frequently rubbing himself against the stall, &c.; or in rubbing one leg against the other, although no eruption appears on the skin; in running thrushes, cracks, or ulcers about the heels; in baldness, or losing the hair on different parts of the

body; in most cases where a course of diuretic medicines are prescribed, bleeding will be necessary before they are given. Regular exercise must by no means be omitted, even during the time they are operating. The use of diuretics should not be continued too long at one time, as they weaken the body considerably; and, as soon as the disorder for which they were given is removed or abated, they should be abandoned.

#### DIURETIC BALL.

Take of Yellow rosin, half-an-ounce:

Linseed powder, three drachms:

Sweet spirit of nitre, sufficient to make the ball.

DIVERS, as they are termed, consist of the scoter, scaup, golden eye, morillon, and others of the duck kind, and are not meant to particularly signify those birds to which naturalists have given the name of divers.

They vary very much both in plumage and size, some weighing two pounds and a half, and others a pound less. In hard weather they frequent the shores and the tide rivers in great plenty, and are almost always at that season fat and in good condition; they do not fly in such large flocks as many of the duck species, and usually close to the surface of the water, and bear very hard blows from the shot without dropping, unless struck upon the head or wing.

The day seems to be spent by these birds between diving and flying to small distances over the water, which they do so low as often to dip their legs in it: they swallow their food whole, and soon digest the shells, which are found crumbled to powder among their excrements. They have been kept tame for some time, and will feed on soaked bread. The flesh tastes fishy in the extreme, and from this cause is allowed by the Roman Catholics to be eaten on fast days and in lent; and, indeed, must be a sufficient mortification.

DOCKING, the operation of cutting off a horse's tail. The manner of performing it has long been this: "First, feel with your finger and thumb, till you have found the third joint from the setting-on of the horse's tail. Then raise up all the hair, and turn it backwards; then taking a very small cord, and wrapping it about that joint, and pulling it as tight as possible, take a piece of wood, with the end smooth and even, and just the height of the horse's tail. Set it between the horse's hinder legs, having first trammelled all his four legs, so that he cannot stir. Lay

his tail upon the wood, and having a very sharp strong knife made for the purpose, set the edge of it as near as possible between the fourth and fifth joints. Then, with a large smith's hammer, strike the back of the knife, and cut the tail off. If any blood issue, the cord is not tight enough, and should be drawn straiter: but if no blood follow, take a red-hot iron, made of a round form, of the full compass of flesh of the horse's tail, and with this sear the flesh till it be encrusted, so that the blood cannot break out. Then loose the cord; and, after two or three days, when the sore begins to discharge, anoint it with hog's grease and turpentine till it be healed."

The following improvement is suggested by Mr. John Lawrence.

"I had heard," says that writer, "of many accidents, some of them fatal, from horses being docked at too late a period, and by bungling blacksmiths; and indeed I had seen several operations of the kind which made me sick. It occurred to me, that colts ought to be docked early, whilst the bones of the tail are tender and gristley; and this operation I ever afterwards performed upon my own horse myself, with a good sharp kitchen-knife, with all possible success, and which I wish to recommend as a general custom. The two last I docked were, one about three months, the other about three weeks, old; the one got by a cart, the other by a bred, horse.—These colts were perfectly tame and handy (a state in which I always choose to have them); and, whilst eating a few carrots, they suffered me to tie their hair up *secundum artem*, and to make the stroke, which curtailed them in an instant, and with so little pain, that they scarcely left their carrots. The usual quantity taken off agrees in length with the width of a man's hand; but perhaps it ought to be rather more, from the consideration of its being done so early. The bred colt was so indifferent about the matter, that he suffered me, about half an hour afterwards, to lay hold of his tail again, and make a ligature to stop the blood. If a flux of blood be not desired, a ligature may be made previous to the operation; but, in case of plethora, dullness, or heaviness about the head and eyes, it may be presumed that bleeding will benefit the colt, and the wound may be entirely neglected. If any application be thought necessary, nothing is so proper as French brandy. No twitching, trammelling, searing with hot irons, nor

any of the Vulcanian apparatus, is here required; and, what will weigh more than all the rest with certain of my readers—no farrier's bill."

DOE. Female of the fallow deer.

DOG. Independent of the beauty of his form, his vivacity, force, and swiftness, the dog is possessed of all those internal qualifications that can conciliate the affections of man, and make the tyrant a protector. A natural share of courage, an angry and ferocious disposition, render the dog, in its savage state, a formidable enemy to all other animals: but these readily give way to very different qualities in the domestic dog, whose only ambition seems the desire to please: he is seen to come crouching along to lay his force, his courage, and all his useful talents, at the feet of his master; he waits his orders, to which he pays implicit obedience: he consults his looks, and a single glance is sufficient to put him in motion; he is more faithful even than the most boasted among men; he is constant in his affections, friendly without interest, and grateful for the slightest favours; much more mindful of benefits received than injuries offered; he is not driven off by unkindness; he still continues humble, submissive, and imploring; his only hope, to be serviceable—his only terror, to displease; he licks the hand that has been just lifted to strike him, and at last disarms resentment by submissive perseverance.

More docile than man, more obedient than any other animal, he is not only instructed in a short time, but he also conforms to the dispositions and manners of those who command him. He takes his tone from the house he inhabits; like the rest of the domestics, he is disdainful among the great, and churlish among clowns. Always assiduous in serving his master, and only a friend to his friends, he is indifferent to all the rest, and declares himself openly against such as seem to be dependant like himself. He knows a beggar by his clothes, by his voice, or by his gestures, and forbids his approach. When at night the guard of the house is committed to his care, he seems proud of

the charge: he continues a watchful sentinel, he goes his rounds, scents strangers at a distance, and gives them warning of his being on duty.

The dog, thus useful in himself, taken into participation of empire, exerts a degree of superiority over all animals that require human protection. The flock and the herd obey his voice more readily even than that of the shepherd or the herdsman; he conducts them, guards them, keeps them from capriciously seeking danger, and their enemies he considers his own. Nor is he less useful in the pursuit; when the sound of the horn, or the voice of the huntsman, calls him to the field, he testifies his pleasure by every little art, and pursues with perseverance those animals which, when taken, he must not expect to divide. The desire of hunting is indeed natural to him, as well as to his master, since war and the chase are the only employments of savages. All animals that live upon flesh, hunt by nature; the lion and the tiger, whose force is so great that they are sure to conquer, hunt alone and without art; the wolf, the fox, and the wild dog, hunt in packs, assist each other, and partake the spoil. But when education has perfected this talent in the domestic dog—when he has been taught by man to repress his ardour, to measure his motions, and not to exhaust his force by too sudden an exertion of it, he then hunts with method, and always with success.

As the dog is of the most complying disposition, so also it is the most susceptible of change in its form; the varieties of this animal being too many for even the most careful describer to mention. Climate, food, and education, all make strong impressions upon the animal, and produce alterations in its shape, its colour, its hair, its size, and in every thing but its nature. The same dog, taken from one climate and brought to another, seems to become another animal; but different breeds are as much separated to all appearance, as any two animals the most distinct in nature. Nothing appears to continue constant with them but their internal conformation; different in the figure of the body, in the length of the nose, in the shape of the head, in the length and direction of the ears and tail, in the colour, the quality, and the quantity of the hair; in short, different in every thing but that make of the parts which serves to continue the species, and keeps the animal distinct from all others. It is this peculiar

conformation, this power of producing an animal that can reproduce, that marks the kind, and approximates forms, that at first sight appear in no degree calculated for conjunction.

From this single consideration, therefore, we may at once pronounce all dogs to be of one kind; but which of them is the original of all the rest, which of them is the savage dog from whence such a variety of descendants have come down, is no easy matter to determine. We may easily, indeed, observe, that all those animals which are under the influence of man, are subject to great variations. Such as have been sufficiently independent, so as to choose their own climate, their own nourishment, and to pursue their own habits, preserve their original marks of nature, without much deviation; and it is probable, that the first of these is even at this day very well represented in their descendants. But such as man has subdued, transported from one climate to another, controlled in their manner of living, and their food, have most probably been changed also in their forms: the dog has felt these alterations more strongly than any other of the domestic kinds; for, living more like man, he may thus be said to live more irregularly also, and, consequently, must have felt all those changes that such variety would naturally produce. Some other causes, also, may be assigned for this variety in the species of the dog: as he is perpetually under the eye of his master, when accident has caused any singularity in his productions, man uses all his art to continue this peculiarity unchanged—either by breeding from such as had those singularities, or by destroying such as happened to want them; besides, as the dog produces much more frequently than some other animals, and lives a shorter time, so the chance for its varieties will be offered in greater proportion.

But which is the original animal, and which is the artificial or accidental variety, is a question which, as was said, is not easily resolved. If the internal structure of dogs of different sorts be compared with each other, it will be found, except in point of size, that in this respect they are exactly the same. This, therefore, affords no criterion. If other animals be compared with the dog internally, the wolf and the fox will be found to have the most perfect resemblance; in fact, there is no perceptible difference: it is probable, therefore, that the dog which most nearly resembles the wolf or the fox externally, is

the original animal of its kind; for it is natural to suppose, that as the dog exactly resembles them internally, so he may be near them in external resemblance also, except where art or accident has altered his form. This being supposed, if we look among the number of varieties to be found in the dog, we shall not find one so like the wolf or the fox, as that which is called the shepherd's dog. This is that dog with long, coarse hair, on all parts except the nose, pricked ears, and a long nose, which is common enough among us, and receives his name from being principally used in guarding and attending on sheep. This seems to be the primitive animal of his kind; and we shall be still more confirmed in this opinion, if we attend to the different characters which climate produces in the animal, and the different races of dogs which are propagated in every country: and, in the first place, if we examine those countries which are still savage, or but half civilized, where it is most probable the dog, like his master, has received but few impressions from art, we shall find the shepherd's dog, or one very like him, still prevailing amongst them. The dogs that have run wild in America, and in Congo, approach this form. The dogs of Siberia, Lapland, and Iceland, of the Cape of Good Hope, Madagascar, Madura, Calicut, and Malabar, have all a long nose, pricked ears, and resemble the shepherd's dog very nearly. In Guinea, the dog very speedily takes this form; for at the second or third generation the animal forgets to bark, his ears and his tail become pointed, and his hair drops off, while a coarser, thinner kind, comes in the place. This sort of dog is likewise to be found in the temperate climates in great abundance, particularly among those who, preferring usefulness to beauty, employ an animal that requires very little instruction to be serviceable. Notwithstanding this creature's deformity, his melancholy and savage air, he is superior to all the rest of his kind in instinct, and, without any teaching, naturally takes to tending flocks, with an assiduity and vigilance that at once astonish and relieve his master.

In more polished and civilized places, the dog seems to partake of the universal refinement, and, like man, becomes more beautiful, more majestic, and more capable of assuming an education foreign to his nature. The dogs of Albany, of Greece, of Denmark, and of Ireland, are larger and stronger than those of any other country. In France, Germany, Spain,

and Italy, the dogs are of various kinds, like the men; and this variety seems formed by crossing the breed of such as are imported from various climes.

The shepherd's dog may, therefore, be considered as the primitive stock from whence these varieties are all derived. He makes the stem of that genealogical tree which has branched out into every part of the world. This animal still continues pretty nearly in its original state among the poor in temperate climates; in the colder regions, he grows less, and more ugly among the Laplanders; but becomes more perfect in Iceland, Russia, and Siberia, where the climate is less rigorous, and the people more civilized. Whatever differences there may be among the dogs of these countries, they are not very considerable, as they have all straight ears, long and thick hair, a savage aspect, and do not bark either so often or so loud as dogs of the more cultivated kind.

The shepherd's dog transported into the temperate climates, and among people entirely civilized, such as England, France, and Germany, will be divested of his savage air, his pricked ears, his rough, long and thick hair, and from the single influence of climate and food alone, will become either a *matin*, a mastiff, or a hound. These three seem the immediate descendants of the former; and from them the other varieties are produced."

How far this last assertion of Buffon, that the shepherd's dog, "from the single influence of climate and food alone, will become either a *matin*, a mastiff, or a hound," may be founded on fact, I am unable to decide; but I am much inclined to doubt it. All animals feel the influence of climate; and we have abundant proof that the very same species, even in latitudes not very widely dissimilar, exhibit marks of the difference of their situation: the lion, for instance, which is never found so high as the temperate latitudes (unless in a state of captivity), to whose very existence a burning sun, or a great degree of heat, seems indispensable, and whose form and manner appear little susceptible of change, is, nevertheless, marked like a graduated scale with the varied effect of latitude. The lion of Mount Atlas is a small, dark, tawny-coloured animal; and, as he approaches the torrid zone, his colour not only becomes much lighter, but he increases in size, strength, and fierceness. The difference is still more manifest between the Esquimaux and the inhabitants of more southern latitudes. On

this principle of reasoning, therefore, it requires no great strength of imagination to suppose that the wild dog assumes various forms and colours, according to situation; and that "the influence of climate and food alone" was not sufficient to produce those varieties above mentioned, but that the natives of remote countries were also resorted to for this purpose.

It is a generally-received opinion, that the wolf and dog, as well as the fox and the dog, will engender, and that the offspring of such a conjunction is capable of procreation; which, if true, would clearly prove that these animals are merely accidental ramifications of the same stock: but I am almost equally inclined to doubt on this head; nor would any thing short of ocular demonstration remove my infidelity upon a subject, which, however, first appearances may seem to favour it, I am perfectly convinced has in general been inconsiderately asserted, and handed from one to another without experiment or reflection.

All the endeavours of M. Buffon to make them engender as he assures us, were ineffectual. For this purpose, he bred up a young wolf, taken in the woods, at two months old, with a *matin* dog of the same age. They were shut up together without any other, in a large yard, where they had a shelter for retiring. They neither of them knew any other individual of their kind, nor even any other man but he who had the charge of feeding them. In this manner they were kept for three years; still with the same attention, and without constraining or tying them up. During the first year the young animals played with each other continually, and seemed to love each other very much. In the second year, they began to dispute about their victuals, although they were given more than they could use. The quarrel always began on the wolf's side. They were always brought their food, which consisted of flesh and bones, upon a large wooden platter, which was laid on the ground. Just as it was put down, the wolf, instead of falling on the meat, began driving off the dog; and took the platter in its teeth so expertly, that it let nothing of what it contained fall upon the ground, and in this manner carried it off; but as the wolf could not entirely escape, it was frequently seen to run with the platter round the yard five or six times, still carrying it in a position that none of its contents could fall. In this manner it would continue running, only now and

then stopping to take breath, until the dog came up, when the wolf would leave the victuals to attack him. The dog, however, was the stronger of the two, but as it was more gentle, in order to secure him from the wolf's attack, he had a collar put round his neck. In the third year, the quarrels of these ill-paired associates were more vehement, and their combats more frequent; the wolf, therefore, had a collar put round its neck, as well as the dog, which began to be more fierce and unmerciful. During the two first years, neither seemed to testify the least tendency towards engendering, and it was not till the end of the third, that the wolf, which was the female, shewed the natural desire, but without abating either in its fierceness or its obstinacy. This appetite rather increased than repressed their mutual animosity; they became every day more untractable and ferocious, and nothing was heard between them but the sounds of rage and resentment. They both, in less than three weeks, became remarkably lean, without ever approaching each other, but to combat. At length, their quarrels became so desperate, that the dog killed the wolf, which was become more weak and feeble; and he was soon after himself obliged to be killed, for, upon being set at liberty, he instantly flew upon every animal he met, fowls, dogs, and even men themselves, not escaping his savage fury.

The same experiment was tried upon foxes, taken young, but with no better success; they were never found to engender with dogs; and our learned naturalist seems to be of opinion, that their natures are too opposite ever to provoke mutual desire.

A young dog shudders at the sight of a wolf; he even shuns his scent, which, though unknown, is so repugnant to his nature, that he comes trembling to seek protection near his master. A dog that is stronger, and knows his strength, bristles up at the sight, testifies his animosity, attacks him with courage, endeavours to put him to flight, and does all in his power to rid himself of a presence that is hateful to him. They never meet without either flying or fighting; fighting for life and death, and without mercy on either side. If the wolf is the stronger, he tears and devours his prey: the dog, on the contrary, is more generous, and contents himself with his victory; he does not seem to think that *the body of a dead enemy smells well*; he leaves him where

he falls, to serve as food for birds of prey, or for other wolves, since they devour each other; and when one wolf happens to be desperately wounded, the rest track him by his blood, and are sure to shew him no mercy.

The dog, even in his savage state, is not cruel; he is easily tamed, and continues firmly attached to his master. The wolf, when taken young, becomes tame, but never has any attachment: nature is stronger in him than education; he resumes with age, his natural dispositions, and returns as soon as he can to the woods from whence he was taken. Dogs, even of the dullest kinds, seek the company of other animals; they are naturally disposed to follow and accompany other creatures beside themselves; and even by instinct, without any education, take to the care of flocks and herds. The wolf, on the contrary, is the enemy of all society; he does not even keep much company with those of his kind. When they are seen in packs together, it is not to be considered as a peaceful society, but a combination for war; they testify their hostile intentions by their loud howlings, and by their fierceness, discover a project for attacking some great animal, such as a stag or bull, or to destroy some more redoubtable watch dog. The instant their military expedition is completed their society is at an end; they then part, and each returns in silence to his solitary retreat. There is not even any strong attachment between the male and female: they seek each other only once a year, and remain but a few days together; they always couple in winter; at which time several males are seen following one female, and this association is still more bloody than the former: they dispute most cruelly, growl, bark, fight, and tear each other; and it sometimes happens, that the majority kill the wolf which has been chiefly preferred by the female. It is usual for the she-wolf to fly from them all with him she has chosen; and watches this opportunity when the rest are asleep.

In a state of nature, I am of opinion, the different species of quadrupeds continue faithful to their own particular tribe, and that various kinds never approach each other for the sake of conjunction; nor were the mare and the ass ever known to produce when wild, though in a state of domestication nothing is more common. Where it possible to reduce the wolf or the fox to that degree of subordination or civilization which so super-

lately distinguishes the domestic dog, a race of mongrels might in all probability be obtained. But to accomplish such an object, infinite trouble would be indispensable, as well as perhaps ages of time; for wolves or foxes must be bred in a tame or domestic state before they could be expected to couple with the dog: and, should the tedious experiment eventually be crowned with success, it is very doubtful whether the mongrel race thus produced, would repay the thousandth part of the trouble.

With regard to the dogs of our country in particular, the varieties are very great, and the number every day increasing. And this must happen in a country so open, by commerce, to all others, and where wealth is apt to produce capricious predilection. Here the ugliest and most useless of their kinds will be entertained merely for their singularity; and, being imported only to look at, they will lose even that small degree of sagacity which they possessed in their natural climates. From this importation of foreign, useless dogs, our own native breed is, perhaps, degenerated, and the varieties now to be found in England are much more numerous than they were in the times of Queen Elizabeth, when Doctor Caius attempted their natural history. Some of those he mentions are no longer to be found among us, although many have since been introduced, by no means so serviceable as those which have been suffered to decay.

He divides the whole race into three kinds. The first is the generous kind, which consists of the terrier, the harrier, and the blood-hound; the gaze-hound, the grey-hound, the leymmer, and the tumbler; all these are used for hunting. Then the spaniel, the setter, and the water-spaniel or finder, were used for fowling; and the spaniel gentle or lap-dog, for amusement. The second is the farm kind; consisting of the shepherd's dog and the mastiff. And the third is the mongrel kind; consisting of the wappe, the turnspit, and the dancer. To those varieties we may add at present, the bull-dog, the Dutch-mastiff, the harlequin, the pointer, and the Dane, with a variety of lap-dogs, which, as they are perfectly useless, may be considered as unworthy of a name.

The blood-hound was a dog of great use, and in high esteem among our ancestors. Its employ was to recover any game that had escaped from the hunter,

or had been killed and stolen out of the forest. But it was still more employed in hunting thieves and robbers by their footsteps.

The land spaniel, which probably had its name from Spain, where it might have acquired the softness of its hair, is well known at present.

**DISEASES OF DOGS.** It has been shewn that wild animals, reclaimed from a state of nature and domesticated, are susceptible of great change and variety in form, colour and character; and owing, no doubt, to being thus compelled to assume in some degree, an artificial mode of life, they are rendered more liable to disorders. Animals in a state of nature are little subject to disease: and though the wild dog subsists on flesh and carrion, it is more than probable he is never troubled with what is distinguished by the appellation of the *distemper*, or any of that long catalogue of disorders, to which the dog is rendered obnoxious after having become the companion of man. However, thus much may be truly observed, that if a dog be properly fed and exercised, has plenty of good clean water, and his bed kept clean, he will not in general be much troubled with disease; and this rule will be found to obtain more particularly if he be kept in the country.

*The Distemper.* The distemper frequently attacks a dog before he has attained his first year. As a preliminary observation, it may be remarked, that the same membrane which lines the nostrils, extends down the windpipe into the lungs; and the distemper, in the first instance, may be regarded as an inflammation of this membrane; which, if not timely removed, extends down to the lungs, where suppuration will soon be produced; when the animal's eye will become dull, accompanied by a mucous discharge, a cough, and loss of appetite. As the disease advances, it presents various appearances, but is frequently attended with twitchings about the head, while the animal becomes excessively weak in the loins and hinder extremities; indeed he appears completely emaciated, and smells intolerably. At length, the twitchings assume the appearance of convulsive fits, accompanied with giddiness, which cause the dog to turn round: he has a constant disposition to dung, with obstinate costiveness or incessant purging.

On the first appearance of the symptoms which I have described, I should recommend the dog to be bled very freely,

and his body to be opened with a little castor oil or syrup of buckthorn : this will generally remove the disease altogether, if applied the moment the first symptoms appear. If, however, this treatment should not have the desired effect, and a cough ensues, accompanied with a discharge at the nose, give him from two grains to eight of tartar emetic (according to the age and size of the dog) every other day. When the nervous symptoms ensue, which I have already described, external stimulants (such as sal-ammoniac and oil, equal parts) should be rubbed along the course of the spinal marrow, and tonics given internally, such as bark, &c.

Of the various remedies, the following was given with success to a dog, so afflicted as to be scarcely able to stand :—

Turbeth's mineral, six grains,  
mixed with sulphur, and divided into three doses, one given every other morning. Let a few days elapse, and repeat the course.

Another :

Calomel, one grain and a half,  
Rhubarb, five grains,  
given every other day for a week.

Another :

Antimonial powder, sixteen grains,  
Powdered fox-glove, one grain,  
made into four bolusses with conserve of roses, and one given at night, and another the next morning, for two days.

I have known whitening administered for the distemper, a table-spoonful every morning, with a little opening physic, occasionally.

I have uniformly found a complete cure effected from copious and repeated venesection in the early stage of the distemper, accompanied with a little opening medicine, syrup of buckthorn, for instance. In the kennel of Sir Harry Mainwaring, the distemper generally swept away a third of the young dogs at least. My system of treating the distemper has since been adopted with the most beneficial effect.

The following scientific description of the distemper and its mode of treatment, cannot fail to be highly interesting :

“ A little black spaniel, six months old, very fat and playful, gradually became listless and irritable ; his eyes suffused with water, his drooping ears, tenesmus, rough coat, dyspnœa, and frequent cough, announced that the disease called the distemper was at hand. In this state he ran about for several days, when the dif-

ficulty of breathing increased. His flanks beat violently, and he shewed signs of feeling great pain when his sides were pressed upon. Soon after, he became slightly convulsed, and, by his continual and melancholy cry, both day and night, proved that he was suffering from severe bodily pain. The convulsions increased, and became incessant ; his debility and emaciation were daily more apparent ; and at the expiration of three weeks he died.

For four days before his death, he lay in a supine, quiet state, perfectly conscious of what was passing near him ; and it was only a few hours previous to his dissolution, that he became comatose, and perfectly insensible. During the whole period of his illness, there was no aberration of mind ; he was irritable, snapped at those who approached him, foamed at the mouth, but did not refuse the small quantities of broth, milk, and other liquids, which were occasionally offered him.

*Dissection.* The carcass was lean, but on opening the abdomen, the omentum, intestines, and other viscera, were loaded with fat. The liver was of a dark dull red colour, congested with blood, the gall bladder distended with greenish bile, the stomach and intestines were discoloured with viscid yellow bile, some of which was contained in the stomach.

The kidneys were free from disease, and the urinary bladder was full of urine.

Thorax or chest—no preternatural adhesions or symptoms of inflammation of the pleura costalis existed. The lungs were highly inflamed, and of a dark brown colour, rendered heavy and solid by the effusion of coagulable lymph. On cutting into their substance, numerous drops of white purulent matter escaped from the bronchiæ, and on a careful examination they were found completely full and choaked up with matter.

The trachea was inflamed, and contained a good deal of pus of the same nature.

The heart and large blood-vessels adjoining were distended with dark, black, coagulated blood ; the substance of the heart itself was much inflamed ; and a small quantity of serum was observed in the cavities of the pleura and pericardium.

A young fox-hound having died of the distemper, I proceeded to ascertain the causes of his death, and commenced with an examination of the nervous sys-

tem. For this purpose a considerable portion of the cranium was removed, by first sawing through the frontal sinuses transversely, and continuing the instrument laterally and downwards through the occipital bone: the bony processes peculiar to carnivorous animals, which assist in forming the falx major, were taken away, and the brain fairly exposed to view.

The frontal sinuses were filled with a thin white fluid, resembling pus, which flowed out freely from the opening made by the saw.

The dura mater was perfectly healthy.

The veins of the pia mater covering the left hemisphere of the cerebrum, were more dilated with blood than those on the opposite side. The substance of the brain was firm, and bore no appearance of disease; nor was there any alteration in the structure of the ventricles. The origins of all the nerves were clear and distinct. The olfactory pair were extremely large, and looked more like processes of brain than nerves. The pineal gland was present in the form of a small pellucid speck, and was seen in its usual situation at the posterior extremity of the third ventricle.

The cerebellum, the pons varolii, and the medulla oblongata, were healthy; on dividing the latter, a little serum was found in the base of the cranium, and on holding the dog up by the hind legs, about two drachms more issued from the sheath of the spinal marrow.

The lateral and cavernous sinuses were filled with dark purple blood.

*Examination of the Spinal Marrow.*—

An incision being carried from the occipital bone down to the sacrum, the muscles were dissected back on each side; and by several applications of the saw, the medulla was laid bare throughout its whole length. The spinal marrow, narrow at its origin, gradually increased in size as it descended to the joints. The dura mater was very firm, thin, and rather opaque. It could easily be separated from the medulla, which was of a beautiful white colour, consisting of two columns, each again divisible into several others; so that there was no appearance of disease to be discovered in the spinal marrow or its membranes; but as the vertebral veins were traced up the spinal canal, they became turgid and more full of blood, and when they had reached the middle of the cervical vertebra, they were greatly distended, and must by their pressure on the spinal marrow have influenced its functions.

Having now completed the dissection of the brain and spine, the thorax and abdomen became the subjects of inquiry.

The trachea was very large, and contained a purulent fluid; its mucous coat was inflamed and corrugated.

The lungs presented a very peculiar appearance, especially the left, a large portion of which was converted into a substance of a yellowish brown, covered with dark black spots, and divided from the remaining healthy part, which was of a florid red colour, by a complete and distinct line of separation.

The discoloured lobes, on being cut into, were solid, and evidently impervious to the admission of air. The bronchial tubes were full of the same thick white pus noticed in my former dissection, and which exuded in large drops.

The right lung was entirely changed into a dark brown mass. The internal jugular and subclavian veins, together with the venæ cavæ, were distended with blood. The heart was enlarged, and the pericardium drawn tight over it. The left auricle and ventricle contained blood; but the right auricle and ventricle were literally gorged to their utmost extent with dark grumous coagulated blood.—There were no marks of preternatural adhesions or inflammation of the pleura costalis, nor was there more than one ounce of serum within its cavity.

*Abdomen.*—There was a good deal of viscid yellowish bile in the stomach; its villous coat was inflamed and corrugated.

The liver was of a dark red colour congested with blood.

The gall bladder was full of a greenish bile.

The urinary bladder contained a straw coloured urine.

The kidneys, omentum, and peritoneum, were in a healthy state; but the intestines seemed to have suffered from the acrimony of the bile.

*Remarks.*—From the preceding dissections it must be evident that the distemper is an inflammatory disorder, more particularly affecting the mucous coats of the bronchial tubes, and that the great congestions of blood found in the heart and other vital organs must arise from the obstruction it meets with in its passage through the lungs. The particular time at which the disorganisation commences must depend on the violence of the symptoms; and it does appear that the disease can be divided into three natural stages:—

1st. The stage of fever and general excitement.

2nd. The deposition of coagulable lymph into the substance of the lungs : and

3rd. The effusion of matter into the bronchial tubes.

In drawing this view of the complaint, the liver is not to be overlooked; and it would seem as if the organ was, by a general irritability of the system, excited to a state of unusual activity, and that thus, by the presence of an increased and vitiated state of the bile, the stomach and bowels were brought into a disordered condition, and their villous coats inflamed.

Upon the epidemic, contagious, or other causes predisposing to the distemper, it is not now my intention to offer any remarks; but I shall proceed to the treatment which appearances after death would indicate.

It is necessary for me to add, that I have no experience of its efficacy, nor do I pretend to say that it will be successful. Indeed the object of this paper is rather to induce those who may have daily opportunities of becoming acquainted with the complaint, by observing its causes, symptoms, and progress, to form an idea of its nature; and, lastly, by the operation of remedies and *frequent dissections*, to arrive at some certain conclusion.

*Treatment.*—At the commencement of the symptoms, or during the first stage of excitement, the dog should be bled freely, according to his age and strength. After which an emetic of tartarised antimony or ipecacuanha should be administered, and its operation promoted by mild bland fluids; moderate doses of calomel, opium, and antimony, should be given every three or four hours, and the excess of bile removed by occasional doses of castor oil. The dog should be immersed for twenty minutes in a warm bath, rubbed dry, and placed in clean warm straw; the temperature of his apartment should be moderately warm, taking great care to exclude the cold air, which must necessarily irritate the lungs. Having continued this plan for forty-eight hours, a mixture, consisting of nitre, fox-glove, and ipecacuanha, should be given three or four times a day until the urgent symptoms have subsided. Stimulants should never be given but when the animal appears much exhausted, and after the preceding measures have been adopted: a little white wine might then be put into the gruel, which should constitute his

food from the primary attack. When recovering, little more than bread-and-milk or nourishing broths will be necessary.

It occasionally happens that the irritability of the stomach is such that no medicines can be retained. Injections in these cases have been attended with beneficial effects; and therefore a solution of starch with laudanum should be thrown up several times in the course of twenty-four hours: a blister also should be applied to the region of the stomach.

With regard to the treatment of the second and third stages, when the first has been violent and neglected, very little can be expected from medicine. Bleeding would be highly injurious; and calomel, opium, and antimony, combined with expectorants, would most probably offer the greatest prospect of success. Strength should be carefully supported by a nutritious diet, but all strong cordials ought to be avoided.

Although it is likely that the fever accompanying the distemper has a peculiar character, I am decidedly of opinion that there is no specific remedy against this complaint; and it is better to point out the indications of cure, than to enumerate a long list of medicines with their respective doses, the selection of which must depend on the circumstances of each individual case.

RICHARD WILLIAMS, Surgeon."  
Aberystwith, June 10, 1825."

I am not aware of any other remedies worth notice, though a great number might be added, if we could give credit to the stories retailed by dealers in dogs, as well as gamekeepers and huntsmen.—Much will be found to depend on good nursing, and particularly to prevent the animal from taking cold.—From what I have witnessed of Blaine's medicine, I should not recommend it.

It is very advisable to inoculate for the distemper. If you can meet with a dog already afflicted, take a little mucus from his nose, and insert it up the nostrils of your whelp, after having prepared him by a dose or two of syrup of buckthorn; if the animal does not take the disease, repeat the operation. By inoculating for the distemper, the disease will be as much less severe, as the inoculated small pox compared to what is called the natural mode of taking it.

A dog rarely, if ever, has the distemper twice; nor does it often attack him after he has attained the age of two years; but frequently makes its appearance before

the animal has reached his twelfth month. A notion became prevalent a few years back, that by inoculating a dog with the cow pock, the distemper would be prevented.

*The Cow Pock.*—Dr. Jenner has asserted that by inoculating dogs for the cow pock, a “disease similar to that which is called the dog’s distemper is produced, but in a very slight degree. What is most remarkable, (adds Dr. Jenner) this inoculation renders them afterwards unsusceptible of that affection.” Dr. Jenner is certainly no mean authority: but, having tried the experiment a number of times, from what I have witnessed, I can assert, that unless much more than ordinary pains are taken in the operation, no disease whatever will be produced; and when, at length, pustules have been raised, they have not been attended with symptoms any way resembling what is called the distemper.

The catalogue of dog diseases is extended in some publications to a puzzling length, where the various ramifications or different stages of each disease receive a new name, in direct violation of that clearness and perspicuity so preferable, indeed so essentially requisite, in a statement of cases, many of which are frequently doubtful even to the skilful and experienced. Young dogs are very subject to worms, and appearances thus produced are too often mistaken for other disorders, receive various appellations, and are treated in the most injudicious manner. I have been informed that the following will cure the distemper; but I have never tried it; and am rather sceptical as to the fact:—

One clove of garlic, given every or every other day, or according to the violence of the disorder.

*Worms.*—Dogs, like human beings, are subject to worm diseases of various kinds. A disorder, generally distinguished by the appellation of *lank madness*, is produced by short thick worms, which occasionally breed in the animal’s stomach and intestines. This, and what is denominated *sleeping madness*, appear to be merely two names for the same disease. When a dog is thus afflicted, he will become lean, though he will feed voraciously; as the disorder increases, his appetite in a great degree forsakes him; his eyes appear dull and drowsy, and he will manifest an almost continual inclination for slumber, without being able, however, to sleep soundly—

Take of calomel, six grains.

Common soap, two scruples. made into two bolusses, one of which to be given at night, and the other the following morning; after two days, the same to be repeated, and in four days more, give the following:—

Extract of colocintida, 2 scruples, made into three bolusses, and one given every morning; on the fourth morning, give the animal a table spoonful of syrup of buckthorn. If the worms should not be entirely destroyed, in a little time repeat the course.

Dogs are often troubled with large worms, which, without medicine, are occasionally voided singly or in clusters.—Their existence may be known by the dog’s voracity and leanness. The best remedy is the preceding, though the following may probably answer the purpose:—

Calomel	3 grs.
Jalap	20 grs.

Golden sulphur of antimony 4 grs. mixed up with butter or lard into one dose. Three of these doses to be given—one every other morning.

A table spoonful or two of linseed oil, given the first thing in a morning, will frequently bring away a quantity of worms: but it can never be depended on as an effectual remedy, for the following reason:—upon the linseed oil being swallowed, those worms with which it comes in contact, that are not fastened on the intestines, but loose, as it were, in expectation of food, will be brought away; but such as are fast to the intestines, (and many will be found so situated) stick like leeches, and thus prevent the effects of the oil. There is nothing so effectual as calomel. Calomel administered externally, in tolerable plenty, upon the human subject, will destroy worms in the stomach. If the worms are situated near the anus, the calomel may be so completely absorbed, when taken inwardly, as to lose its effect before it reaches that part; some tobacco smoke blown up the anus (which may be easily done by inserting the thin end of a pipe) will most completely destroy these noxious vermin, and they will be voided, most likely, in prodigious numbers.

The remark which was made on the last article would equally apply in this place, respecting the numerous remedies prescribed for the same disease. What are mentioned throughout are such as will be found to answer the purpose; and to

give a number of doubtful and ineffectual recipes, for the sake of making a long list, or giving a false air of importance to the subject, would be as perplexing to the reader as it would be contemptible and even dishonest, in the writer.

However, for worms, generally speaking, the following may be regarded as a sovereign remedy, and there are few cases which it will not effectually cure—take

Linseed oil, half a pint.

Oil of turpentine, two drachms.

Repeat the dose, if necessary.

*Convulsions or Fits.*—Complaints of this nature are sometimes caused by an accumulation of worms in the stomach, which in the first stage create giddiness, and end in violent convulsive paroxysms. When the complaint is to be attributed to worms, the animal will have an itching at the nose and fundament, and will sneeze frequently. In this case, the best treatment is what has been already prescribed for worms. When convulsions proceed from other causes, which may be generally known by a wild appearance in the animal's eyes, frothing at the mouth, when labouring under the most violent paroxysms of convulsion, the dog may be recovered by being thrown into the water; perhaps a bucket of water thrown over him might answer the purpose: but this is merely a temporary relief; and to eradicate the disease, recourse must be had to something more effectual. In the first place, the animal should lose a few ounces of blood, (from three to six ounces, according to his size and strength) when the following should be administered:—

Jalap 1 scruple.

Cream of tartar, half a drachm.

Water 1 oz.

mixed; half taken the morning after the dog has been bled; the other half in two hours after, well shaken:—a rowel should afterwards be put in the neck, and kept open for a considerable time: the following should then be given:—

Peruvian bark, half an ounce.

Water, half a pint.

boiled for a few minutes and strained; then add, sweet spirit of nitre, one drachm: a table spoonful to be given every two hours, the animal afterwards to be kept on a mild nourishing diet.

When convulsions arise from indigestion, the following has generally been found efficacious:—from two to eight grains of tartar emetic (according to the age and size of the dog), and in two days after give the following:—

Calomel, six grains.

Barbadoes aloes, half a drachm.

Divide into six doses, and administer one every, or perhaps every other, morning, as you may judge the patient can bear it; when you may give tonics, as recommended under the head *Distemper*.

What is called the *megrin*, or giddiness in the head, is a species of fit, and may be removed by bleeding. The same disease is, by some, denominated *falling madness*, (a ridiculous name, certainly,) from, I suppose, the animal occasionally falling from giddiness. When thus afflicted, the dog will frequently rub his feet against the sides of his mouth, and appear as if he had a bone in his throat. Any of these symptoms will give way to the treatment just described; and where the disorder is not very violent, it may generally be removed by bleeding, which, as it has formed a principal feature for the last few pages, it may not be amiss to say a word or two on the best mode of performing the operation under a distinct head.

*Bleeding.*—In speaking on this subject, I am not supposing that the sportsman is a member of the medical profession in any of its branches, but sufficiently skilled in anatomy to know a vein from an artery, which is all the knowledge requisite for performing the operation of bleeding a dog. A vein may be distinguished from an artery by its having no pulsation; if an artery of any consequence should be divided, the blood will flow in irregular gushes, it will be difficult to stop, and may cause the death of the dog. However, there is little danger of such an unpleasant circumstance happening, and an ordinary degree of attention is quite sufficient to obviate it. The most convenient and the best place to bleed a dog, is to open a vein (the jugular vein) *longitudinally*, in the side of the neck, round which a cord should be first tied; and if the sportsman is not expert at handling a lancet, he may purchase a fleam at any of the shops where surgical instruments are sold, which, by means of springs, is so contrived, that the greatest bungler need be under no apprehension. Those who sell this instrument will describe the method of using it, which indeed is so obvious at first view, as to render elucidation superfluous in this place.

If, after the vein is opened, the animal should not bleed freely, pressure a little below the orifice will cause the blood to flow. When sufficient blood has been

taken, (eight ounces, if a strong dog) the bleeding will generally subside; should this not be the case, a little fur from a hat will stop it, or the lips of the orifice may be drawn together with a needle and thread.

The vein should be opened *longitudinally*, as I have already observed; as, if opened in a transverse direction, it may be difficult to stop the bleeding, owing to the circumstance of the incision opening every time the dog holds down or stretches out his head.

Caustic or hot iron will stop bleeding, even when an artery is divided; or it may be sewn up.

*Cold and Cough.*—A cough arises from an irritation of the lungs, and may be produced by a cold or otherwise; it is generally the effect of cold, and may be removed by

Antimonial powder	5 grs.
Calomel	4 grs.

made with honey into two bolusses, and given in the evening for two nights successively.

If a dog should be afflicted with a cough, in the first place examine his throat, in order to ascertain if any pieces of bone are lodged there, as such a circumstance will cause a dog to cough for weeks. If the cough arises from cold, administer a dose or two of syrup of buckthorn.—Should the cough still continue, give tartar emetic, as described under the head *Distemper*.

*Formica, Scab in the Ears.*—A little mercurial ointment rubbed upon the affected parts every two or three days, will very soon effect a cure.

*Canker in the Lips.*—Rub the affected parts with alum water two or three times a day.

Or, rub with bole ammoniac and burnt alum two or three times a day.

*Swellings in general.*—See *Inflammation*, p. 224.

*Films in the Eye.*—Bathe the affected part twice a day with water in which a little vitriol has been dissolved, (the size of a large horse-bean to a pint of spring water) and in a minute or two wash it in clear water.

Or bathe with the following lotion twice a day:—

Sulphate of copper,	one scruple.
Water,	four ounces.

*Sprains.*—Sprains are painful swellings of the ligaments and tendons of the joints, and are caused by too great exertion of the limbs, of which the tendons become

relaxed. They should be well rubbed with the following twice a day:—

Camphor, two drachms.

Brandy, one ounce.

When the camphor is well dissolved, add one ounce of sweet oil, and shake them well together. Should this not have the desired effect, try the following:—

Spirit of hartshorn, two drs.

Sweet oil, six drs.

well shaken, and applied as the other.—Give a spoonful or two of syrup of buckthorn.

N. B. As sprains are attended with inflammation, this should be got rid of in the first place by fomenting with warm water four or five times a day, and the following lotion applied:—

Extract of lead, two ounces.

Water, one pint.

Should any stiffness remain after the inflammation has totally subsided, apply a blister.

*Wounds, and to stop an Effusion of Blood.*—The following will be found very effective in wounds:—

Spirit of sal-ammoniac, opodeldoc, sweet nitre, equal parts.

Wine, half quantity.

Spirit of turpentine, half quantity.

If an artery is wounded, it may be known (as before observed) by the blood gushing out, (not flowing regularly) and assuming a florid appearance. If a vein is wounded, the blood will be darker coloured, and flow regularly.

Wounds may be divided into two classes—*incised*, or those cut with a sharp instrument: and *contused*, or those inflicted with any thing blunt or heavy.

Slight wounds require little or no attention; but supposing a serious incised wound, the first operation should be cutting, or rather shaving, the hair from around the wound, when, if the blood continues to flow, it should be stopped by filling the wound with bits of sponge or dry lint; if the wound be in the dog's limbs, a bandage tied very tight just above it will materially assist in stopping the flow of blood, should not the sponge or lint be found sufficient. The edges or lips of the wound should afterwards be stitched, or drawn close together with adhesive plaster cut into slips long enough to extend three or four inches on each side; the number of slips must of course be regulated by the size of the wound: plenty of lint or soft rag should be laid on, over which a roller or bandage must be applied to confine the dressing, which should not

be removed for four or five days. The wound should afterwards be dressed with Turner's cerate, sparingly spread on rag, and the bandage as before, and great caution used not to remove the adhesive plaster till the third or fourth dressing. A table spoonful of syrup of buckthorn may be occasionally given to keep the animal's bowels open; and he must be muzzled, or otherwise so secured as to prevent his tearing away or disturbing the bandage.

*Contused* wounds are more painful than incised; always swoln, ragged, and not attended with much hæmorrhage or flow of blood: no attempt should be made to bring the edges together, but a cold poultice applied, made with oatmeal and the following lotion:—

Goulard's extract of lead, one drachm,  
Vinegar, two ounces,  
Water, one pint.

The poultice should extend over the swelled parts surrounding the wound, and be renewed three or four times during the day. When the wound begins to suppurate or discharge, unaccompanied with blood, the cold poultice should be changed for a warm one, consisting of oatmeal and water in which there is a little grease, and renewed three times a day as warm as the dog can bear it. In a few days the matter will be completely discharged, when the wound should be dressed daily with yellow basilicon spread on rag, and a long roller applied tightly over.

N. B. Whenever *fungus* or proud flesh appears, it should be touched with blue stone.

*Inflammation.* — Inflammation arises from various causes, but is distinguished by the part affected becoming swoln, dry, and hot. A slight degree of inflammation will generally subside without the aid either of medicine or external application. Bleeding in the neck will frequently remove an inflammation—or the application of leeches to the affected part, having previously shaved the hair off. If the swelling or tumour becomes larger, soft, and shining, matter is forming, when warm poultices should be applied, as described under *Contused Wounds*, and the same treatment adopted. When the matter is completely formed (which may be known by the fluctuation of the fluid upon a slight pressure,) if the skin is very thin, a deep opening or incision should be made with a lancet on the prominent part; but if hardness is felt, the tumour must remain till it breaks itself. After the tumour is emptied, care should be taken

that the air does not penetrate, or the wound will be much more difficult to heal.

When a dog's eyes become inflamed, and assume a red and fiery appearance, bleeding will generally relieve him.

Dogs, however, are not very subject to inflammation, and, generally speaking, will be troubled with few diseases, if properly dieted and exercised. Dogs kept in towns are much more subject to disorders than such as are kept in the country. Confinement is always injurious to health.

*For the Bite of another Dog.*—See the article *Wounds*, &c. page 223.

*Sore Feet.*—Styptic tincture, or, if this cannot be procured, salt and water. “The most essential point about the dog is a good foot; for, without a good, firm foot, he can never hunt long. I never look at a dog which has a thin, flat, wide, and spread foot; they are not worth twopence.

It has been a constant custom with me to wash my pointers' feet with strong salt and water after the day's sport. I have found my error, and am convinced that it is a wrong practice. I never altered my method until three years ago. A gamekeeper in Suffolk, seeing that a boy was washing my dogs' feet with strong salt and water (his name was Cooper), said to me, ‘Sir, I think you do wrong to wash your dogs' feet in salt and water at this early part of the shooting season (it was the first week in September), at this time, Sir, when the ground is uncommonly dry, and as hard as a rock. If you will feel their feet, you will find there is a considerable degree of feverish heat in the dog's feet, from having hunted all the day on hard and dry ground. A dog, Sir, in such weather, should have his feet suppled and comforted. As long as the ground is dry and hard, I always wash my dog's feet with warm soap and water, and clean them well, particularly between the toes and balls of the feet; this comforts his feet, allays the heat, and promotes the circulation in the feet. In the more advanced period of the season, when the ground is very wet, then salt and water may be proper.’ I approved much of the reasons he gave; it showed the sense of his practice, and the folly of mine: since that period I have taken his advice.”—*General Hanger.*

*For extracting Thorns.*—Thorns may be generally extracted with the thumb and fore-finger nails; or recourse may be had to the assistance of the pen-knife in the same way as the sportsman would ex-

tract a thorn from his own finger. The dog will frequently perform the operation with his mouth. If the wound festers, the thorn may be squeezed out.

*To bring Hair upon a Scalded Part.*—Fresh hog's lard rubbed frequently upon the affected part, will re-produce hair; indeed, I am inclined to think that animal fat in general will have the desired effect. Fresh goose-grease, or the fat of fowls, unmixed with salt, will answer the purpose equally well. Vegetable oils are of too dry a nature, and their effects, as applied to the growth of hair, pernicious. Yet there are not wanting quacks who daily advertise the sale of oil for the growth of hair on the human head, and, by way of the strongest possible recommendation, specifically state, that it is extracted from vegetables! This is lamentable; but it is still more so, that such numbers of the unthinking become the dupes of these ignorant pretenders, whose existence is a stigma on the liberality of the public.

*To destroy Fleas, Lice, &c.*—Take of white arsenic, one drachm,  
Water, one gallon,

Soft soap, one quarter of a pound, boiled for ten minutes; then take it off the fire and let it stand to settle; then pour it off into another vessel, leaving about half-a-pint at the bottom, which throw away, and dress with the water.—A certain remedy.

Linseed oil, or Scotch snuff, rubbed well all over the body, is a temporary remedy. A good washing with common soap and water will perhaps answer the purpose.

In hot weather dogs are much troubled with fleas; and if the sportsman is anxious for their comfort, he will find it necessary to use the above several times during the summer. Clean beds, and cleanliness in general, act as preventatives.

*To recover the Sense of Smell.* When a dog's olfactory organs become affected, it will frequently be found to arise from colds, costiveness, or other causes, which a dose or two of opening physic seldom fails to remove. A little sulphur or syrup of buckthorn will have the desired effect.

*For Dogs that have taken Poison.*—For all vegetable poisons, vinegar has been supposed to be a specific. At all events, whether vegetable or mineral poison has been swallowed, the sooner it is discharged from the stomach, the better.

Take of sulphate of copper, half-a-drachm  
Water, six ounces.

Give two table spoonsful every five min-

utes, until effectual vomiting has taken place; when a strong dose of castor oil should be administered, followed by nourishing diet.

Whatever will cause instantaneous vomiting may have the desired effect. If a dog has swallowed poison, and no better remedy happen to be at hand, almost any kind of oil (rancid or otherwise) poured down the throat is advisable. The poison will most likely be either nux vomica, arsenic, or corrosive sublimate; however, let the poison be what it will, the best remedy is the following—

Ipecacuanha, fifteen grains,  
Water, two table spoonsful, mixed.

Should it not operate in fifteen minutes, repeat the dose.—After the operation—

Take of prepared kali, three drachms,  
Water, one ounce.

Give a table spoonful every fifteen minutes, which will most likely produce vomiting and purging. Afterwards nourishing diet.

*Antidote for Vegetable Poisons.*—M. Drapiez has ascertained, by numerous experiments, that the fruit of the fewillea cordifolia is a powerful antidote against vegetable poisons. He poisoned dogs with rhus toxicodendron, hemlock, and nux vomica. All those that were left to the effects of the poison died; but those to whom the fruit of the fewillea cordifolia was administered recovered completely, after a short illness. M. Drapiez also took two arrows which had been dipped in the juice of manchinele, and slightly wounded with them two young cats. To the one of these he applied a poultice, composed of the fruit of the fewillea cordifolia, while the other was left without any application. The wound of the former speedily healed; while the other, in a short time, fell into convulsions, and died.

It is very difficult, however, to save the life of a dog that has taken poison. Nux vomica is what the base-minded generally use for the purpose. If recourse can be had to the process before described, the moment the animal has swallowed the baneful drug, I should have no doubt of success; but if only a few minutes elapse, the cure is extremely doubtful. I have witnessed several instances, in all of which the animals died, though every exertion was used for their preservation. Perhaps the stomach-pump might be successfully applied.

*Sickness, or a Foul Stomach.*—A foul stomach proceeds from indigestion; therefore eight or ten grains of tartar emetic

may be very beneficially given, followed, in a day or two, by a purge of syrup of buckthorn.

Dogs are very liable to a foul stomach; but this is more particularly the case with such as are tied up or confined. If you tie a dog to a kennel for a few days, the moment you loose him, he will run in search of grass to eat, the broad blades of which he prefers; this will frequently cause him to vomit: whenever the animal is troubled with sickness or a foul stomach, he will uniformly have recourse to eating grass, though vomiting does not always follow.

A dog never perspires; but whenever he is unwell, his eyes very strongly exhibit the change, are a certain index of the state of his health, and assume a languid, a dull, or a fiery appearance, according to the nature of the disorder with which he is afflicted. The powers of digestion in a dog do not appear to be promoted by exercise. If you take a dog into the field to hunt with a full stomach, he will throw up the contents of it in a few minutes, or at least in a short period. If you suffer him to sleep after a hearty meal, the digestion is rapid and healthy. This may be regarded as a general rule throughout animated nature. Give a dog a good supper on the evening prior to hunting, and the next morning he will require little or nothing. I generally give my dogs a crust of bread in the morning when going out, which, however, they will not always stop to eat, so great is their anxiety for the expected diversion. Little food, and that of a light nature, will be found to answer best upon violent exercise; hence a man walks or labours much better after a breakfast, composed principally of tea or coffee, than after a heavy dinner. Cows, horses, and animals in general, retire to rest after filling their bellies; a full stomach, I have no doubt, is the best to sleep upon; and I therefore differ very widely from those physicians who represent a good supper as injurious to repose.

*The Common Mange.*—This disorder is very infectious, and originally proceeds from dirty beds, bad food, and filth in general. It has a loathsome, scabby, dirty appearance, somewhat similar to the itch in human beings, and, like that disease, contains animalcula in each of the pustules. It may be cured with the following:

Oil of tar,

Sulphur vivum,

Train oil, of each an equal quantity,

with which the dog should be well rubbed several times, a day or two clapsing between each rubbing. Sulphur given internally will be of service.

Another:—

Flowers of sulphur, half-an-ounce,  
Hog's lard or butter, one ounce,  
well mixed, and rubbed completely over the animal twice a day, giving a tea spoonful of the flowers of sulphur every evening in a little molasses. Keep the animal confined alone, and the moment the cure is effected, give him a clean bed.—As the disease is very infectious, without great care, all your dogs will become disordered.

Mercurial ointment rubbed on the parts affected will remove this disease; but it is rather a dangerous remedy, and will kill a weak animal, if not carefully administered:—muzzle the dog.

An infusion of fox-glove leaves, I have reason to believe, will answer the purpose: it is the cleanest remedy; and though I have not had sufficient experience to pronounce its infallibility, I have no hesitation in recommending it:—put a handful of fox-glove leaves into a quart or three-pint jug, pour boiling water upon them; and, when cold, rub the dog every day for three or four days. The dog need not be muzzled—as soon as dressed he will attempt to lick, but will not take a second taste.

The following I have seen successfully used:—

Sulphur, two ounces,

Mercurial ointment, two drachms,

Hog's lard, four ounces,

well mixed: with which rub the dog every other day—three or four dressings will generally be sufficient. Two drachms of aloes, mixed up with the above, will not injure the composition, and will probably prevent the animal licking himself—otherwise, muzzle him. Chlorate of lime, I am informed, will cure the common mange.

*The Red Mange.* The disorder called the *red mange* does not appear to be nearly allied to what is so well known by the common appellation of *mange*, but to be a species of disease within itself, seated in the skin, and not always infectious amongst dogs lying together, but almost invariably communicated by a bitch to her litter of whelps, particularly if she had it upon her during the time she was in pup. This disorder is most malignant in its effect; the incessant and severe itching, which, from all observation,

seems accompanied by a burning heat, and this too increased by the perpetual biting and scratching of the tortured animal, give such parts of the frame as are severely affected, the appearance of having been scalded by some boiling liquor, with a consequent loss of hair. It is this distinct kind of mange that so constantly baffles dog-doctors and dog-mongers of every description, and reduces them to their *ne plus ultra*, where the fertility of invention can go no further. It is, perhaps, the most deceptive disorder to which any part of the animal world can become unluckily subject; for when it has (seemingly and repeatedly) submitted to, and been subdued by, some of the combinations of combustibles before described, it has as suddenly, as repeatedly, and as unexpectedly, made its re-appearance with all its former virulence. Great care, nice attention, and long experience, have discovered one or two modes of perfect eradication. Let half an ounce of *corrosive sublimate* be reduced in a glass mortar to an impalpable powder; to this, by a very small quantity at a time, add two ounces (half a gill) of spirits of wine; and, lastly, one pint of rain or river water, and, with a sponge dipt in the solution, let every part palpably affected be well washed, every third day, till thrice performed; then leave three clear days, and repeat the former ceremony of thrice as before; letting three *mercurial purging balls* be given at the equal distances of three or four days, and not the least doubt of cure need be entertained, if the mode prescribed is properly and judiciously attended to.

Of the red mange General Hanger thus speaks:—"My dog had the mange; not very bad, but something much worse with it: he had eight or ten large blotches on his body, as big as large hazel nuts. I sent for an old man who made a livelihood by curing dogs: he took a bottle out of his pocket, and first dabbed the blotches with a bit of tow, each two or three times.—He then stopped about five minutes for that to dry in and penetrate; after which he took a pot of ointment, and rubbed the dog in well, for at least ten minutes, under the fore legs, and on the belly, but *particularly on the back bone*. He then desired me not to wash the dog, or let him go into the water; telling me, he would call in about five days. When he called, the dog was apparently well; so much so, that he said he did not think it necessary to rub the

dog again: however, I made him dab the blotches again, and rub once more in. When he called to be paid, I told him, that upon my honour, if he would discover how the liquid and ointment were made, I would give him two guineas, and never discover it till after his death. He consented. The liquid is thus made:—Half an ounce of quicksilver is put into a bottle, with half an ounce of oil of turpentine, for about eight hours before using it: shake the bottle frequently, and shake it always when you use it, for there will be a sediment at the bottom. The ointment is thus made:—Take half an ounce of quicksilver; put it in a bottle with half an ounce of oil of turpentine; let it stand for eight hours, shaking the bottle frequently; then take four ounces of hog's lard, and by degrees, mix both together, a little of each at a time, till the whole be incorporated. He told me that he always carried two pots of ointment with him, one stronger than the other, in case of a dog being very bad with the mange. The strongest ointment was made with only *three ounces* of hog's lard, but with the same quantity of quicksilver and turpentine."

The following is an effectual cure:—

Train oil, one ounce,  
Black sulphur, one ounce,  
Liquid blister, half an ounce,

to be rubbed on the dog every other day.

*For the bite of the Adder, &c.* The adder is not uncommon in some parts of England, and is occasionally to be met with, in the heat of summer, among sedges, and in marshy places. It differs from the snake in not being so long, the latter being found from three quarters to a yard long; the former seldom, or never, reaching three quarters of a yard; there is an appearance of malignity in the countenance of the adder, which does not obtain in that of the snake, the head of which is not so blunt as that of the adder; while the tail of the latter tapers more abruptly, and it is generally found of a more dusky colour. There is, however, another very essential difference:—the snake is destitute of teeth; while the adder is not only prepared in this respect, but has one particular tooth, on each side of the jaw, which has a communication with a sort of alembic, situated in the reptile's head, and which contains the venom: in this tooth, there is a slit; and when the creature becomes irritated and bites, the pressure thus occasioned upon the tooth,

causes the venom to ooze through the slit, and it is thus injected into the blood.

I have heard of a reptile, called the *slow worm*, the bite of which is said to be venomous; but I never saw one. The snake is perfectly harmless; the bite of the adder or viper will be attended with serious consequences if a remedy is not speedily applied. The remedy, however, is simple—the immediate application of sweet oil rubbed on the affected part, counteracts the effects of the venom most surprisingly: as I have witnessed it, I speak with confidence. Indeed, I am of opinion, that any vegetable oil (or animal either, perhaps) will answer the purpose; and have little doubt, that what will cure the bite of the adder will cure that of the slow worm also. Yet, for a further illustration of this subject, I will borrow the account of a favourite author. I am aware that the same account has already appeared in various publications; but, from a conviction that much good may result from its becoming generally known, I shall transcribe it without hesitation:—

“One William Oliver, a viper catcher, of Bath, was the first who discovered this admirable remedy. On the first of June, 1735, in the presence of a great number of persons, he suffered himself to be bit by an old black viper (brought by one of the company) upon the wrist and joint of the thumb, so that drops of blood came out of the wound: he immediately felt a violent pain both at the top of his thumb and up his arm, even before the viper was loosened from his hand: soon after he felt a pain resembling that of burning, trickling up his arm; in a few minutes, his eyes began to look red and fiery, and to water much; in less than an hour, he perceived the venom seize his heart, with a pricking pain, which was attended with faintness, shortness of breath, and cold sweats; in a few minutes after this, his belly began to swell, with great gripings and pains in his back, which were attended with vomitings and purgings; during the violence of these symptoms, his sight was gone for several minutes, but he could hear all the while.

He said, that in former experiments he had never deferred making use of his remedy longer than he perceived the effects of the venom reaching his heart; but this time, being willing to satisfy the company thoroughly, and trusting to the speedy effects of his remedy, which was nothing more than olive oil, he forbore to apply any thing, till he found himself

exceedingly ill and quite giddy. About an hour and a quarter after the first of his being bit, a chafing-dish of glowing charcoal was brought in, and his naked arm held over it as long as he could bear, while his wife rubbed in the oil with her hand, turning his arm continually round, as if she would roast it over the coals: he said the poison soon abated, but the swelling did not diminish much. Most violent purgings and vomitings soon ensued; and his pulse became so low, and so often interrupted, that it was thought proper to order him a repetition of cordial potions: he said he was not sensible of any great relief from these, but that a glass or two of olive oil drank down seemed to give him ease. Continuing in this dangerous condition, he was put to bed, where his arm was again bathed over a pan of charcoal, and rubbed with olive oil heated in a ladle over the charcoal, by Dr. Mortimer's direction, who was the physician that drew up the account. From this last operation he declared that he found immediate ease, as though by some charm; he soon after fell into a profound sleep, and after nine hours' sound rest, awaked about six the next morning, and found himself very well; but in the afternoon, on drinking some rum and strong beer, so as to be almost intoxicated, the swelling returned, with much pain and cold sweats, which abated soon, on bathing the arm, as before, and wrapping it up in brown paper soaked in the oil.”

*Burns and Scalds* assume a very different appearance, according to the degree of heat or violence by which they are occasioned; if slight, and the skin only irritated, they are easily cured by instantly dashing the part affected in cold water, or constantly applying it till the pain and irritation have ceased; if slight blisters rise, they should not be opened at first, as is generally recommended; for if the air penetrates, it frequently produces an ulcer or sore. When a burn or scald is more severe, it must be constantly kept wet with the rag dipped in the following lotion:—

Goulard's extract of lead, two drachms,

Water, half a pint,

and the part kept as quiet as possible. Strong spirits, or oil of turpentine, is also serviceable when immediately applied; but the lotion is the most successful treatment either in scalds or burns. After the third or fourth day the blisters should be opened, but the skin not removed, and

then dressed with the following ointment:—

Olive oil, half an ounce,  
Goulard's extract of lead, one ounce,

well mixed together, and spread on lint or soft rag, with a bandage over moderately tight.

When burns or scalds are so severe as to destroy the flesh from the bone, warm

poultices of oatmeal and water should be applied, and then treated as *suppuration*. See the article WOUNDS, &c.

*The Hydrophobia.* This is a dreadful disease, and has received a very appropriate name, as human beings, *but not dogs*, when afflicted with this little understood malady, uniformly testify an abhorrence of water, and, I believe, of fluids in general, and even shining substances.

“ When Sirius reigns, and the sun's parching beams  
Bake the dry gaping surface, visit thou  
Each ev'n and morn, with quick observant eye,  
'Thy panting pack. If, in dark sullen mood,  
The glouting hound refuse his wonted meal,  
Retiring to some close obscure retreat,  
Gloomy, disconsolate, with speed remove  
'The poor infectious wretch, and in strong chains  
Bind him suspected. Thus that dire disease  
Which art can't cure, wise caution may prevent.”

SOMERVILE.

The hydrophobia affords a striking instance of successful quackery in the avidity with which the *Ormskirk medicine* was purchased, till within these few years that the imposture has been exposed. This compound of calcined oyster shells, elecampane, roach alum, and bole ammoniac, was originally administered gratis; but no sooner was it discovered that the medicine was eagerly sought after, than the sale of it was advertised; agents were appointed in different parts; and many hundreds purchased and took the medicine who had been bitten, but not by *mad dogs*. A dog accustomed to the country is generally alarmed when he approaches a town or village; the shaking of a cobbler's apron, or some such thing, is frequently resorted to by the lower orders—the terrified animal takes to his heels, and will most likely snap at any person who attempts to impede his progress. Nothing is heard but the cry of mad dog! and many who have been bitten under such circumstances, have called in the assistance of the Ormskirk medicine, and have thus been willing to suppose a disorder prevented, which did not exist in the dog, and which, of course, could not be communicated.

The venders of the Ormskirk medicine, however, made the most of the matter—its infallibility was *puffed* upon the public in the most barefaced manner; and it was even publicly stated, that such was the virtue of the medicine, that even after the hydrophobia had made its appearance, the disease could be removed

by taking it. Cases, with fictitious names, were stated, and the grossest falsehoods resorted to, in order to levy contributions with more plausibility upon the credulity of the unthinking. I believe, at present, no person who wishes to preserve even an appearance of character, will attempt to palm the medicine upon the world; but it has still its supporters; and a number of old women, in various parts of Lancashire, still practice the deception, and show considerable dexterity in proping its falling reputation.

The recipe was obtained by the late Mr. Hill's father, who resided near Ormskirk, from an itinerant tinker, in the year 1704. The medicine is thus prepared:—take one tea-spoonful of prepared (calcined) oyster shells, one knife point full of roach alum, as much elecampane, in powder, and half a tea-spoonful of bole ammoniac; all to be powdered finely, and given to the patient in the morning fasting, in a little wine and water, or small beer: at the same time the wound is to be dressed with a preparation, varying from that just described only in a greater portion of roach alum.

Not one dog in twenty, reputed mad, is so in reality—the cure, or rather the prevention, therefore, is certain in many instances; and where it happens otherwise, and the dog was labouring under the hydrophobia, the result is most melancholy: but then it is immediately and unblushingly asserted, that the medicine had not operated in a proper manner—it had not remained upon the stomach, or

been taken in sufficient quantity; and thus the cheat continues, though on a much more circumscribed scale.

The fact is, that the only certain remedy hitherto discovered for this dreadful disease, is the application of the knife:—the blood becomes infected by the saliva from the dog's teeth; and unless the bitten part can be immediately cut out, death will most likely be the result, though the precise time will be very uncertain; for so capricious is this malady, that, after infection, it sometimes lies dormant, as it were, in the system for months, sometimes for weeks; while instances, I believe, are not wanting, where it has appeared in all its terrible symptoms in the course of a few days.

It is possible that a person might be bitten by a mad dog, and yet escape the hydrophobia: if, in the act of biting, the animal's teeth pass through a thick woollen coat, or other garment, so that his teeth in passing through are wiped dry, he might inflict a wound without any of the infectious saliva or fluid reaching it.

Respecting the bite of a mad dog, Dr. Vandeburgh very judiciously observes—“Not a moment should be lost to destroy the poison from the wound (even if only on supposition of the animal being mad); many remedies are recommended, but should not be trusted to; the only effectual method is to destroy the foundation of the poison, and give the following course of medicine:—the part bitten must be entirely cut out with a sharp instrument, and the edges of the wound seared with a red-hot iron, to prevent the smallest particle of poison remaining; afterwards, warm poultices of oatmeal and water to be applied as hot as the patient can possibly bear, to produce a quick and copious discharge of matter or suppuration. The following pills should be given:—

Calomel, one scruple,

Opium, half-a-scruple,

well mixed, and divided into ten pills of equal size, one pill to be taken every four hours; two drachms of strong ointment of quicksilver to be well rubbed in on the thighs and arms morning and evening, which, with the medicine, must be continued till the mouth becomes sore and spitting is produced: when matter discharges from the sore, it should also be dressed with strong ointment of quicksilver thickly spread on lint, and the poultice continued over it: this treatment must be pursued for the space of one month, then the wound healed with Turner's cerate spread on lint,

but the mouth kept sore and slight spitting prolonged for at least two months, as hydrophobia has been known to make its appearance five and six months after the bite of the animal: sea-bathing is strongly advised; but I would always recommend the foregoing treatment in preference, a trial of which should not be omitted, if the poison was destroyed at first by cutting; neither if the bite has happened some time, nor even when the following symptoms have taken place: the part bitten becoming tender and inflamed, uneasiness and stupidity, frightful dreams, convulsions, eyes red and watery, pain all over the body, difficulty in swallowing, great thirst, and when liquid is only brought before the patient, he appears choked, accompanied with trembling and shivering over the whole body; vomiting bile frequently occurs, attended with great thirst and fever: the last symptoms are raging and foaming at the mouth, spitting at the by-standers, and strong convulsions, as if drawn double. No patient should be given over till the last moment: the mercurial friction should be tried, and the prescribed medicine given, while he exists, as there is hope of recovery by perseverance in the foregoing method.

“The patient should be kept on very low diet, and no spirits or wine be used.”

The following are the progressive symptoms of hydrophobia: when a dog becomes melancholy, droops his head, forbears eating, seems to forget his former habits, and as he runs snatches at every thing; if he often looks upwards, and that his tail at its setting on be rather erect, and the rest of it hanging down; if his eyes be red, his breath strong, his voice hoarse, and that he drivels and foams at the mouth, you may be satisfied of the approaches of hydrophobia; and the only thing that should be done is instantly to despatch him, however great a favourite he may be. If at this period he should remain at liberty, he will certainly leave his home: he goes as fast as he can; and the mischief that may happen, owing thus to a mad dog breaking away, and running over an extent of country, is incalculable, as he spares no living creature.

The following accurate description, from the pen of Mr. Youatt, appeared in the *Sporting Magazine*, September, 1825:—

“The symptoms of rabies in the dog are the following, and nearly in the order in which they usually appear:—an earnest licking, or scratching or rubbing, of some particular part; sullenness, and a

disposition to hide from observation; considerable costiveness and occasional vomiting; an eager search for indigestible substances, as bits of thread, hair, straw, and dung; an occasional inclination to eat its own dung, and a general propensity to lap its own urine. The two last are perfectly characteristic circumstances. The dog becomes irritable; quarrels with his companions; eagerly hunts and worries the cat; mumbles the hand or foot of his master, or perhaps suddenly bites it, and then crouches and asks pardon. As the disease proceeds, the eyes become red; they have a peculiar bright and fierce expression; some degree of strabismus or squinting very early appears; not the protrusion of the *membrana nictitans*, or haw, over the eye, which, in distemper, often gives the appearance of squinting, but an actual distortion of the eyes; the lid of one eye is evidently more contracted than the other; twitchings occur round that eye; they gradually spread over that cheek, and finally over the whole face. In the latter stages of the disease, that eye frequently assumes a dull green colour, and at length becomes a mass of ulceration.

After the second day, the dog usually begins to lose a perfect control over the voluntary muscles. He catches at his food with an eager snap, as if uncertain whether he could seize it; and he often fails in the attempt. He either bolts his meat almost unchewed, or in the attempt to chew it suffers it to drop from his mouth. This want of power over the muscles of the jaw, tongue, and throat, increases, until the lower jaw becomes dependent, the tongue protrudes from the mouth, and is of a dark and almost black colour. The animal is able, however, by a sudden convulsive effort to close his jaws, and to inflict a severe bite.

The dog is in incessant action: he scrapes his bed together, disposes it under him in various forms, shifts his posture every instant, starts up, and eagerly gazes at some real or imaginary object: a peculiar kind of delirium comes on: he traces the fancied path of some imaginary object floating around him: he fixes his gaze intently on some spot in the wall or partition, and suddenly plunges and snaps at it; his eyes then close, and his head droops; but the next moment he starts again to renewed activity: he is in an instant recalled from this delirium by the voice of his master, and listens attentively to his commands; but as soon as his master ceases to address

him, he relapses into his former mental wandering.

His thirst is excessive, (there is no hydrophobia in the dog) and the power over the muscles concerned in deglutition being impaired, he plunges his face into the water up to the very eyes, and assiduously, but ineffectually, attempts to lap.

His desire to do mischief depends much on his previous disposition and habits. I have known it not to proceed beyond an occasional snap, and then only when purposely irritated; but with the fighting dog the scene is often terrific. He springs to the end of his chain; he darts with ferocity at some object he conceives to be within his reach; he diligently tears to pieces every thing about him; the carpet or rug is shaken with savage violence; the door or partition is gnawed asunder; and so eager is he in this work of demolition, and so regardless of bodily pain, that he not unfrequently breaks one or all of his tusches. If he effects his escape, he wanders about, sometimes merely attacking those dogs which fall in his way; and at other times he diligently and perseveringly hunts out his prey: he overcomes every obstacle to effect his purpose; and, unless he has been detected in his march of death, he returns in about four-and-twenty hours, completely exhausted, to the habitation of his master.

He frequently utters a short and peculiar howl, which, if once heard, can rarely be forgotten; or if he barks, it is a short, hoarse, inward sound, altogether dissimilar from his usual tone.

In the latter stages of the disease, a viscid saliva flows from his mouth, with which the surface of the water that may be placed before him is covered in a few minutes; and his breathing is attended with a harsh grating sound, as if impeded by the accumulation of phlegm in the respiratory passages.

The loss of power over the voluntary muscles extends, after the third day, throughout his whole frame, and is particularly evident in the loins: he staggers in his gait; there is an uncertainty in all his motions; and he frequently falls, not only when he attempts to walk, but when he stands balancing himself as well as he can. On the fourth or fifth day of the disease he dies, sometimes in convulsions, but more frequently without a struggle.

After death there will invariably be found more or less inflammation of the mucous coat of the stomach; sometimes confined to the rugæ, at other times in

patches; generally with spots of extravasated blood, and occasionally intense, and occupying the whole of that viscus. The stomach will likewise contain some portion of indigestible matter, (hair, straw, dung,) and occasionally it will be completely filled and distended by an incongruous mass. The lungs will usually present appearances of inflammation, more intense in one, and generally the left lung, than in the other. Some particular points and patches will be of a deep colour, while the neighbouring portions are unaffected. The sublingual and parotid glands will be invariably enlarged; and there will also be a certain portion of inflammation, sometimes intense, and at other times assuming only a faint blush, on the edge of the epiglottis, or on the rima glottidis, or in the angle of the larynx at the back of it."

When the human species become unhappily the subjects of this calamity, though in particular instances some variation may be observed, yet the first symptoms are generally the same; these are, torpid disquietude in the wound (or seat of injury), attended with slight intervening itchings, ultimately amounting to pain, and much resembling rheumatic affection. It continues to extend itself to the surrounding parts; and, at length, from the extremities it expands its poisonous power to the viscera; the cicatrice, if there has been a wound, begins to swell, inflammation hourly increases, till, at length, a serous bloody ichor is discharged, and this alone may be considered the primary and invariable prognostic of certain hydrophobia. These leading symptoms soon become progressively general, bearing with them every appearance of confirmed rheumatism; they are fluctuating, quick, acute, and of the spasmodic, convulsive kind; they suddenly attack the patient, severely affecting the head, neck, and principal joints; a dull, drowsy pain, often seizes the head and neck, breast, abdomen, and even vibrates along the back bone. The patient is gloomy and inclined to solitude, murmurs much, seems lost in reflection, is forgetful, inattentive, and prone to sleep; at times agitating starts denote the mind to be disordered; by turns he is attentively watchful; his slumbers become disturbed; and suddenly awaking from those, convulsive appearances soon follow.

A deafness is sometimes complained of; the eyes are watery; the aspect sorrowful; the countenance pale, and the face contracted: sweat breaks out about the temples; an unusual flow of saliva, slimy and

viscid, at length comes on, with a dryness of the fauces, a foulness of the tongue, and a disagreeable smell (or rather fetid effluvia) from the breath. As the symptoms already recited increase, the second stage advances: a fever commences, which at first is mild, but makes with gigantic strides the most rapid advances to extremity; it is accompanied with hourly-increasing horrors, and all the alarming concomitants of mental derangement. Wakefulness becomes perpetual; violent periodical agitations ensue; the mind is evidently more and more disturbed; a delirium follows, at which critical moment an invincible aversion to *fluid, glass, or* any polished or shining body, is plainly perceived. A constriction of the gullet takes place, and an incredible difficulty of swallowing ensues; liquids are offered, and are attempted to be taken, but the disgust and loathing become so predominant, that they are most violently declined; and this symptomatic dread and aversion so wonderfully increases, that, upon the very appearance of any watery fluid, the greatest horror comes on, and the most shocking muscular distortions ensue; if the liquor is attempted to be forcibly pressed upon them, the experiment is rejected by an instantaneous succession of the most horrid gesticulations, and convulsive distortions, in which every ray of reason seems to be absorbed. Upon a temporary cessation of so distressing a paroxysm, the poor unhappy patient now murmurs, mourns, and groans most miserably; loses, by degrees, all knowledge of his dearest friends and most familiar acquaintance; and their presenting themselves before him is the very critical moment, when all of this description give proof of their desire to bite, which, in the attempt, bears no ill affinity to the similar snappings of a village cur.

. Awful to relate, reason returns at intervals, and he feelingly laments his own calamity, and deplores his own incapacity. A consciousness of approaching dissolution is perceptible even to himself, and he seems truly resigned to the singularity of his fate. Severe pain and consequent heat producing thirst, a desire to drink is displayed; but Nature shrinks from her office; in vain the patient raises his hand to touch the vessel, it almost magically produces instant tremor—the hand recedes, and he sinks into the most afflicting despondency. Conscious, likewise, of his constantly-increasing inclination to bite, he, in his rational moments, makes signals to warn his

friends of the danger, and keep themselves at a distance. Towards the conclusion of this dreadful and most melancholy scene, the fever and parching thirst increase, the tongue becomes swelled and protruded, foam issues from the mouth, strength fails, cold sweats come on, the stricture on the breast increases, as well as the other predominant symptoms, until, in a long succession of convulsive struggles, all-powerful death closes the scene.

The cause of the hydrophobia is utterly unknown; and its effects hitherto appear to have baffled every remedy which has been tried for its removal. Copious and repeated venesection was, a few years ago, announced to the world as a cure for the hydrophobia, and instances were given in order to confirm it: it is true, they came in a questionable shape on account of the distance they had to travel, being chiefly from the East Indies: however, the method just mentioned has been tried in this country, and found unavailing.

The *alisma plantago* was introduced as a remedy, but, on repeated trial, has proved ineffectual.

Another remedy has been introduced. This new remedy comes from a distance; but let us not reject it merely on that score. The account has appeared in several medical works, and was first published, it seems, by Dr. Muller, of Vienna—a scientific physician, now resident at Paris. The German physician says, he received the particulars from M. Marochetti, a Russian surgeon, who informed him, that, during his residence in the Ukraine, in the year 1813, he was called on to attend *fifteen* persons who had been bit by a mad dog, when some old men requested him to treat the unfortunate people according to the directions of a neighbouring peasant, who had acquired a great reputation for curing the hydrophobia. M. Marochetti allowed the peasant to attend *fourteen*, reserving one to himself, a female of sixteen, who was cauterized and treated in the usual way, and expired *eight days after the attack*. The peasant gave to the fourteen persons placed under his care a strong decoction of the tops of the flowers of the *yellow broom* (a pound and a half a day). He examined twice a day the under part of the tongue, where he had generally discovered little pimples, containing, as believed, the hydrophobic poison: these pimples really followed and were observed by Marochetti himself. As they formed, the peasant opened them, and cauterized the parts with a red-hot

needle; after which, the patients gargled with the decoction mentioned above. The result of this treatment was, that the fourteen patients were cured, having only drank the decoction for six weeks. Marochetti then states, that, five years afterwards, he himself had an opportunity of giving this treatment another trial. Twenty-six persons who had been bitten by a mad dog, were put under his care, viz. nine men, eleven women, and six children: he ordered the decoction of the tops of the flowers of yellow broom to be given them as soon as possible; and upon an attentive examination of their tongues, he discovered pimples on five men, three children, and all the women. Those who were most wounded were afflicted on the third day; the others on the fifth, seventh, or ninth. One of the women who had been slightly bitten in the leg, had no appearance till the twenty-first day. The seven who were free from pimples took the decoction of broom for six weeks, with success. M. Marochetti thinks that the hydrophobic poison, after having remained in the wound, fixes itself under the tongue, in the orifices of the ducts of the submaxillary gland, which are situated on the sides of the frænum. The inflammation, of which the little pimples are the result, has a peculiar appearance. The time in which these pimples appear, is generally between the third and ninth day after the bite. If they are not opened before twenty-four hours after their appearance, the venom is absorbed, and the patient is lost.

I shall be extremely anxious to hear of the success of this mode of treatment nearer home; for I must confess I cannot place implicit confidence in the narrative.

Were I bitten by a mad dog, I should as soon as possible cause the wound to suppurate, and continue the suppuration for a considerable period.

*Dumb Madness.*—Upon the disease, erroneously denominated Dumb Madness, I will relate what fell under my own observation, and from which a tolerable idea of the disorder may be formed:—In the month of May, 1823, a pointer whelp was presented to me by a friend, which I knew to be as well bred as any in the kingdom, and on that account, I, of course, prized him more highly. The dog was whelped on the 16th of April, of the same year; and as soon as I received him, a kennel was appropriated for his use in the open air, well littered with wheat straw, and kept clean. He had

full liberty, and a clear stream of water close at hand, to quench his thirst whenever he thought proper. The dog, as might be expected, was remarkably healthy; and, at seven months old, had become an amazingly fine animal: at this period, he experienced a slight attack of the distemper, which immediately gave way to bleeding and a dose of tartar emetic; and in three or four days he was restored to perfect health. His colour was a perfect jet black; he was larger than common, and altogether, the finest young pointer I ever saw. On the 8th of January, (of the following year,) I observed the dog keep his mouth almost continually open, the inside of which appeared darker coloured than usual, and somewhat swelled. I immediately bled him copiously, which, however, produced no visible alteration; on the contrary, the next day all the symptoms had evidently increased, and I observed that he was unable to swallow, though he made many attempts both to eat and drink, particularly the latter; but the water or the milk, which, by putting his nose into the vessel, he contrived to get into his mouth, uniformly run out again, and he appeared utterly unable to pass it down his throat: he licked his fore-legs very much, and seemed to have a trifling discharge of mucus, or saliva: but all this time the dog appeared not only perfectly sensible, but even in good spirits, and evidently experienced but little pain. A sporting acquaintance, who saw him, said the disease was what was distinguished by the appellation of *dumb madness*, which seems to me altogether a ridiculous term; and supposing this to have been the disorder with which my dog was affected, I can testify that the term is very improperly applied, as the animal in question regularly barked on the approach of a stranger, though in a different tone, and with more difficulty than usual. However, I immediately searched authorities for *dumb madness*, with a view to ascertain the proper mode of treatment. In an old writer, (the author of the "Gentleman's Recreation,") I found it thus described:—"The dog that is troubled with dumb madness will not feed, but holds his mouth *wide* open continually, putting his feet to his mouth frequently, as if he had a bone in his throat." Now, though my dog kept his jaws somewhat distended, his mouth was not *wide* open, but only partially so, and that he was able to shut it I can safely attest, as I saw him many times

close his jaws, though he never kept them more than a second or two in that position; further, the animal frequently licked his fore-legs, but I never saw him raise his feet, or otherwise use indications similar to those adopted by a dog when he seems to have a bone in his throat; and therefore the cases did not appear to agree.

I had next recourse to the "Sportsman's Dictionary, or Gentleman's Companion;" the third edition of which was published in 1783, which contained the following observations:—"Dumb madness *lies in the blood*, and causes the dog not to feed, but to hold his mouth always wide open, frequently putting his feet to his mouth, as if he had a bone in his throat."

To be brief—I perused every thing within my reach, on the subject of dogs and their diseases, but without gaining the least information; and, as the disorder, at least in the form in which it presented itself, was new to me, I began to entertain fears for the life of my dog, and the sequel will prove they were but too well founded. I have already remarked, that I first perceived the disease on the 8th of January, and the dog continued much in the same way for four successive days, during which, all his faculties appeared very little, if at all, impaired. He would follow me into the field, and even hunt, frequently attempting to drink, and, in order to accomplish that desirable object, would thrust his nose into the water, instead of attempting to lap; but he never succeeded in forcing any of the fluid down his throat: his sense of smell was as perfect as ever; and, indeed, though he evidently became very lean, he might be said to be in good spirits till the morning of the 13th, when I found him very languid, his eye had lost its lustre, and death was evidently fast approaching. He was perfectly sensible, and whenever I approached and spoke to him, he raised his heavy eyes, and by these, as well as by the movement of his tail, appeared grateful for my attention. Towards the evening he made a last effort to swallow food, but was not able. On the following morning he was stretched on his side, and had every appearance of death, only that a breathing, at very long intervals, proved that the vital spark was not absolutely extinct. Some few hours afterwards he was perfectly lifeless; and I was resolved, if possible, to ascertain the cause of his death. For this purpose I called in the

assistance of a skilful veterinary surgeon, and the animal was dissected in my presence. On opening the body, it was abundantly evident that the dog had been starved to death; or, in other words, had died for want of food. The lungs, the liver, and, indeed, all those parts of the animal organization, were totally unaffected, and manifested not the slightest symptoms of disease; the same remark will equally apply to all parts of the throat, and also to the brain; and the only affection that could be discovered, was in the salivary glands, which were triflingly swelled. On the whole, I feel a perfect conviction, that the disorder of the dog was a glandular affection, which, by rendering him incapable of swallowing sustenance, caused his death.

Of the cure, should a similar case come under my observation, I feel confident; and I have been thus minute for the information of sportsmen in general, particularly as I have been informed, that the disorder which I have attempted to describe or something very much resembling it, has carried off, within the last few years, great numbers of valuable dogs, especially in Yorkshire. Should a similar case occur with any of my dogs, I should force food, (nourishing broth, for instance,) down the throat, with an instrument adapted for the purpose; and if I found it impossible to get it down, I would inject it into the bowels, when a sufficient quantity would be taken up by the absorbents, to sustain life till the disease of the glands abated. In the first place, I should feel a disposition to bleed the afflicted animal, as this would prevent any superabundant pressure of blood upon the parts affected, which I might perhaps rub well with mercurial ointment.

It is a lamentable fact, that so little attention has been paid to the diseases of this invaluable animal, though no creature which has yet been taken under human protection affords so good an opportunity for observation, or is so much entitled to the assistance and kind offices of its master. The dog has become a domestic of the most familiar description, whose greatest delight is in administering to the pleasures of the sportsman, or those by whom his services are called into action; his civilization may be said to proceed in the precise ratio with that of human nature, and he uniformly takes his tone from the circumstance or the situation of his master. As he has closely associated himself with man, therefore, he has

brought upon himself a train of diseases; resulting from his artificial mode of life; and from which, in a state of nature, there is little doubt, but he is altogether exempt. In fact, living under the same roof, and in the same manner, as his master, he seems to be afflicted something in the same way; and, upon close examination, it will be found, that many of his disorders bear a strong resemblance to those in man, and would, I have little doubt, give way to a somewhat similar treatment. Thus circumstanced, it seems unaccountable that the medical treatment of this faithful creature should have been so neglected. Generally speaking, whenever a dog is attacked with any disease, little trouble is taken in his recovery; food is offered him, and if he is able to eat it and recovers, it is all right; but it very frequently happens, that the moment he exhibits symptoms of indisposition, he is suspected of hydrophobia, and, without any attempts to alleviate his pains, he is placed in a situation of security, and either suffered to pine away, or is prematurely despatched. This may not apply altogether to sportsmen, perhaps; though many of these, I have not the least doubt, pay but little attention to the matter. In kennels of hounds, and other large dog establishments, there is a certain method followed; or, in other words, there is a list of disorders which is supposed to be understood by the huntsman, or gamekeeper, and, in like manner, a regular list of antiquated applications or medicines is placed, as it were, opposite the disorders: now, if the medicines were positively applicable to the diseases, is it likely that the latter are so understood, that one is not frequently mistaken for another? Or, can it be supposed, that the persons in question are sufficiently skilled in the science of healing, so as to discern those turns or alterations by which the same disease assumes a different form, and, accordingly, requires different treatment?—This is too much to expect. Huntsmen and gamekeepers, also, are generally much attached to their dogs, and seldom fail to show them considerable attention, when they are diseased; and though I may have met with some who possessed acute perception and sound sense, yet, in order to acquire a thorough knowledge of the subject on which I have been speaking, a superior education seems indispensable, as well as much more extensive practice than could possibly be afforded by any one dog establishment in the king-

dom: if extensive practice be necessary to the physician and the surgeon, why not to the dog doctor also? In any science or profession where the success must depend very much upon the practitioner's powers of perception, some degree of education is not only indispensable, but superior abilities or considerable genius also. It is not likely, that the requisite opportunities and qualifications will be found united in many instances; and, under such circumstances, I would strongly advise sportsmen to pay as much attention to their diseased dogs as possible; and whatever reliance they may place upon their servants, it can do no harm to watch the progress of the disorder themselves.

Many sportsmen of the old school, in their treatment of the diseases of dogs, seem to have resorted to superstitious notions, and to have disregarded true philosophy altogether; so much so, indeed, that it is amusing to read many of their ideas on the subject. It is possible, however, that dog-diseases might formerly have existed, which are unknown at the present day; but a disease called the *yellow*s, that has sometimes appeared in kennels of hounds, I never saw described in any publication, but "*Johnson's Hunting Directory*;" nor is it generally known even among sportsmen, though, wherever it has appeared, its effects have been very violent, and frequently attended with fatal consequences.

*The Yellow*s.—This would appear to be a disease peculiar to the kennel, which makes its appearance in all ages of the dog. In the first approaches of the *yellow*s, the animal loses his appetite, and of course appears dull. On turning up his eye-lids, a yellow appearance presents itself; the inside of his flanks exhibits a similar hue or colour. Hence it would seem that the disorder is something of a bilious nature; or, at least, it assumes a complexion which would seem to warrant such a conjecture. At all events, if it be not immediately checked, it will end with the death of the dog. This disease, which is not of an ancient date, made considerable havoc in many kennels, till at length, the following treatment was found efficacious:—As soon as the dog is perceived to be ill, four grains of calomel should be administered to him, and he should be kept warm during their operation. Then take, Rhubarb, 1 oz.—Aloes, half an oz.

Castile soap, half an oz.

Æthiop's mineral, half an oz.

These should be mixed up with syrup of buckthorn, and made into boluses about the size of a nutmeg; one of which should be given every morning for three successive days, when one may be administered every other morning for a week, or longer if necessary. For this method of treating the *yellow*s, I am indebted to W. Head, Sir Harry Mainwaring's huntsman; which, he informed me, he had found successful almost invariably.

*Lameness in the Shoulder* may also be regarded as a disease of the kennel.—This seems to be produced by damp kennels, and may be prevented by the administration of warmth, though it cannot always be cured when it has taken place; yet I am inclined to think that warmth is the best remedy, as well as an absolute preventive.

**DOTTEREL.** The length of the dotterel is about ten inches. The bill is not quite an inch long, and is black. The forehead is mottled with brown and grey: the top of the head is black; and over each eye there is an arched line of white, which passes to the hind part of the neck. The cheeks and throat are white; the back and wings are of a light brown, inclining to olive, each feather margined with pale rust colour. The fore part of the neck is surrounded by a broad band of a light olive colour, bordered below with white. The breast is of a pale dull orange; the middle of the belly black; and the rest of the belly and the thighs are of a reddish white. The tail is olive brown, black near the end, and tipped with white; and the outer feathers are margined white. The legs are of a dark olive.

These birds are migratory; appearing in flocks of eight or ten, about the end of April; and staying all May and June, when they become very fat, and are much esteemed for the table. They are found in tolerable plenty in Cambridgeshire, Lincolnshire, and Derbyshire; but in other parts of the kingdom they are scarcely known. They are supposed to breed among the mountains of Westmoreland and Cumberland.

The dotterel is in its manners a very singular bird, and may be taken by the most simple artifice. The country people are sometimes said to go in quest of it, in the night, with a lighted torch or candle; and the bird on these occasions will mimic the actions of the fowler with great archness. When he stretches out an arm, it stretches out its wing; if he moves a foot, it moves one also; and every other mo-

DUN-BIRD, or POCHARD, *pp.* 242 & 649.

tion it endeavours to imitate. This is the opportunity that the fowler takes of entangling it in his net. Willoughby, however, cites the following case:—six or seven persons usually went in company to catch dotterels. When they found the bird, they set their net in an advantageous place; and each of them holding a stone in either hand, they got behind it, and striking the stones one against the other, roused it from its natural sluggishness, and by degrees drove it into the net. The more certain method of the gun has of late superseded both these artifices.

**DOUBLE.** A term in hare hunting. The hare is said to double, when, being considerably a-head of the hounds, she throws herself to the right or left, and returns in a parallel line to the track she went before; getting into which, she is said to run the foil. If, during the chase, she lays down, she is then said to squat.

**DRAG** is a sporting term in hunting, and used exactly in the same sense with the fox, as trail is with the hare. Upon throwing the hounds into covert, to draw for a fox, any single hound giving tongue, is said to challenge, and to have hit upon drag; that is, to have come upon the foot or scent of the fox, where he had been in the night or early in the morning, before he retired to secrete himself for the day.

**DRAGON.** The property of Tregonwell Frampton, Esq. of Moreton, Dorsetshire. Mr. Frampton was keeper of the running horses at Newmarket, to their Majesties William III. Queen Anne, George I. and George II. He was styled, for a great number years, “the father of the turf” and died on the 12th of March, 1727, aged 86.

This extraordinary character was born in the reign of king Charles I. when the sports of horse racing commenced at Newmarket; he was owner of the celebrated horse Dragon, who ran several times there with great success, but the account thereof, as also that of his pedigree, has been for many years lost.

The most remarkable event in the lives of this gentleman and his horse Dragon, is most pathetically depicted by Dr. John Hawksworth (in No. 37 of the *Adventurer*) in the following words; supposed to be spoken by the horse in the *Elysium of Beasts and Birds*.

“It is true,” replied the steed, “I was a favourite; but what avails it to be a favourite of caprice, avarice, and barbarity? My tyrant was a wretch, who had gained a considerable fortune by play,

particularly by racing. I had won him many large sums; but being at length excepted out of every match, as having no equal, he regarded even my excellence with malignity, when it was no longer subservient to his interest. Yet I still lived in ease and plenty; and as he was able to sell even my pleasures, though my labour was become useless, I had a seraglio, in which there was a perpetual succession of new beauties. At last, however, another competitor appeared: I enjoyed a new triumph by anticipation; I rushed into the field, panting for the conquest; and the first heat I put my master in possession of the stakes, which amounted to ten thousand pounds. The proprietor of the mare that I had distanced, notwithstanding the disgrace, declared with great zeal, that she should run the next day against any gelding in the world, for double the sum: my master immediately accepted the challenge, and told him, that he would the next day produce a gelding that should beat her: but what was my astonishment and indignation, when I discovered that he most cruelly and fraudulently intended to qualify me for this match upon the spot; and to sacrifice my life at the very moment in which every nerve should be strained in his service!

“As I knew it would be in vain to resist, I suffered myself to be bound: the operation was performed, and I was instantly mounted, and spurred on to the gaol. Injured as I was, the love of glory was still superior to the desire of revenge: I determined to die as I had lived, without an equal; and having again won the race, I sunk down at a post in an agony, which soon after put an end to my life.”

When I had heard this horrid narrative, which indeed I remembered to be true, I turned about in honest confusion, and blushed that I was a man!

Dragon raced in the latter end of the reign of Queen Anne; and the newspapers of that period would no doubt have mentioned so extraordinary a circumstance had it really happened; it would also have been recorded in various other publications. Frampton resorted to many stratagems to accomplish his purposes, and in consequence was much and justly suspected; but I can never consent to place this in the catalogue of his misdoings, unless I had much better authority than the flimsy and mawkish testimony of Dr. Hawksworth. The truth of the following relation there is not much rea-

son to question: A celebrated horse, called "Merlin," was matched for a considerable sum of money to run against a favourite horse of Mr. Frampton's at Newmarket. Immediately on the match being closed there was great betting amongst the north and south country gentlemen. After Merlin had been some little time at Newmarket, under the care of one Heseltine, Mr. Frampton's groom endeavoured to bring him over to run a *private trial*, at the stated weights and distance agreed upon in the match; observing, by that means, they might both make their fortunes. Heseltine refused, but in such a manner as to give the other hopes of bringing him over. In the mean while, Heseltine took the opportunity of communicating, by letter, into Yorkshire, the proposed offer, to Sir W. Strickland, Bart. who was principally concerned in making the match. Sir William returned for answer, that he might accept it; and instructed Heseltine to be sure to deceive his competitor, by letting Merlin carry seven pounds more weight than that agreed upon, and at the same time laying a particular injunction to secrecy. —Soon after Heseltine received this hint, he consented to the proposal; but previous thereto, Mr. Frampton had given his groom similar instructions. The two horses were prepared, started, and ran over the course agreed to in the articles of the match; when Merlin beat his antagonist something more than half a length after excellent running. This being communicated by each party by their secret and faithful grooms, who both rode the trial, flattered each with certain success, Merlin's friends observing, that, as he had beat the other with seven pounds more weight, he would win his race easily. On the other hand, says Mr. Frampton, as my horse ran Merlin so near with seven pounds extra weight, he will win the race to a certainty. Immediately after, bets were made to an enormous amount and it has been asserted that there was more money sported on this event than was ever known, gentlemen not only staking all the cash they were able to advance, but their other property also. At length the important hour arrived for the determination of this great event, and each party flushed with the prospect of success; the south country gentlemen observed to those of the north, that "they would bet them gold, while gold they had, and then they might sell their land." The horses started, and the

race was won by Merlin, by about the same length as in the secret trial. In a short time after, it became known, to the mortification of its inventor, Tregonwell Frampton, Esq.

DRAG-NET is the particular net in use with those nocturnal depredators who exert their utmost endeavours to devastate every water in the neighbourhood where they reside. It is of sufficient length to extend from one side of any moderate pond, moat, or river, to the other; and having the bottom plentifully loaded with leads at equal distances, with the addition of assistants at each end to bring the two together, encloses of course all the fish within its draught.

DRAWING is a term used in fox and stag-hunting, when drawing a covert to find either of the former, or an outlying deer; it being customary to say, "We draw for a fox;" "we try for a hare."

DRAW-NET—formerly used with the setting dog, but superseded by the fowling-piece.

DRAY. A squirrel's nest.

DRENCH, or DRINK. Any medical composition prepared in a liquid form, and given to horses or cattle for the cure of disease. A distinction is made between the two in general; it being the custom to say *drink* for a horse—*drench* for a cow.

DRESSING. The periodical application of friction, by means of brushes, cloths, &c. to the hides of animals, with a view both to cleanliness and health. To the horse, as the nobler animal, is allotted the greatest share of this salutary and gratifying process; the inferior descriptions of cattle being left to rub off their impurities as well as they can.

On this subject Mr. Clarke observes, that as exercise acts as an assistant to the heart in promoting the circulation of the fluids, so does friction on the surface of the body, by means of the curry-comb and brush, contribute to forward the circulating fluids, and promote that insensible perspiration through the pores of the skin which is so conducive to the health of the animal.

Currying and brushing of horses that are kept in stables is done not merely with a view of taking away the dust and dirt that may be collected on the hair; but, when properly performed, it is a very beneficial operation to horses, as they naturally perspire much through the pores of the skin. This appears indeed from the effects which result from the omission of it. When this operation is neglected,

or slightly performed, the perspirable matter hardens in the pores; it remains at the roots of the hair, and has the appearance of a whitish or brownish dust, and sometimes like small scales, which, for the most part, creates an itching: the skin, at the same time, generally appears dry and hard, the hair stares or stands on end, instead of lying smooth and shining.

Columella observes, that the bodies of cattle ought to be rubbed down daily, as well as the bodies of men; and oftentimes it does them more good to have their backs well rubbed down, than their bellies filled with large quantities of provender.

From what is known of the salutary effects of friction on the human body, it will be evident how much benefit may be derived to horses (if not to inferior cattle) from good rubbing and dressing as frequently as possible; but more especially when they are cold and chilly, after being over-heated, or from being suffered to stand in the cold air tied at the stable-door. Dressing becomes then the more necessary, as it produces a gentle heat and warmth all over the surface of the body, prevents stagnation of the fluids in the vessels on the surface, and promotes a free perspiration.

However, though the greatest advantages may be derived to horses when in health by daily rubbing their bodies, yet Mr. Clark observes, there are cases of disease in which it may prove hurtful in certain parts; as in swellings of the legs, attended with inflammation, where rubbing with the hands is frequently recommended; or when there is a discharge of sharp ichorous matter from the pores, or in cracks in the heels, attended with great pain, or in wounds or punctures. As all these are attended with more or less inflammation, friction then proves hurtful on these parts; for the heat there being already considerable, friction will add to it, and, of course do mischief: besides, as the vessels, in such cases, are too full and distended with blood, the force that is applied in rubbing the legs renders these vessels liable to be ruptured.

Washing horses with cold water, in order to clean them, by throwing whole pailfuls on their bodies when they are over-heated, immediately after posting, &c. which is now so commonly done on the post-roads, is a practice concerning which Mr. Clark speaks doubtfully; though it is said that no bad consequences follow from it. If they are well rubbed down immediately

after such exercises, there is, he thinks, no need for washing them with cold water, and then rubbing them afterwards; as the latter operation is sufficient to clean them, without running any risk by washing them with cold water. He thinks it probable, that the only thing which prevents immediate bad consequences following from this manner of treatment is, that such horses are very soon afterwards put to active exercise on the road, by which they are put into strong perspiration again; for not only our experience (the above instance only excepted), but the experience of past ages, have demonstrated the bad consequences that commonly follow the too sudden application of cold, whether it be water or air, to an animal body when over-heated. Hence, it should seem most prudent to avoid the washing of horses, when they are over-heated, with cold water, more especially in cold chilly weather, as it answers no good purpose, and certainly is not without danger. For the same reason, washing the dirt off horses' legs, belly, and thighs, with cold water, immediately after they have performed a stage and have been over-heated, should likewise be avoided till they are cool. If well rubbed afterwards, and thoroughly dried, it will be very proper; but this is very seldom put in practice.

DRIFT, is the act of driving a common. This ceremony takes place once, twice, or thrice, a year, (according to the custom of the place) to ensure and continue the privilege of the lord of the manor, as well as to preserve the rights of the parishioners. The cattle upon the commons and wastes being all driven to some particular spot, are there examined, and their owners ascertained: those belonging to parishioners (or such as have right of common) are immediately liberated, and return to their old lair; others, the property of aliens, are impounded, and the owner is fined such reasonable sum as may be thought equitable by the bailiff of the manor. No owner being found, the object (whatever it be) is called an estray, which being cried three times in the nearest market towns, and not claimed within twelve months and a day, it then becomes the property of the lord of the manor.

DRINK, a liquid form of medicine occasionally administered to horses and other cattle.

In drenching horses, it is usual to draw up their heads pretty high with a cord fastened round the upper jaw, holding up

the horse's head in that posture till the drink has passed down into his stomach.

Mr. Clark, of Edinburgh, observes, that great care should be taken to compound the medicine properly, and not to mix drugs of opposite qualities, which do not unite or mix intimately together.—Common farriers, totally ignorant of chemistry and pharmacy, do not attend to this circumstance. Hence, the drenches which are frequently given to horses are so very nauseous and disagreeable, that they will not swallow them, and they are consequently rejected and spilt in the administering; or, when swallowed, as they sometimes are, with reluctance, they occasion such a nausea or sickness, that they too frequently increase rather than alleviate the complaints they are intended to remove. Thus, when balsams are to be administered, if they are not properly blended with some mucilaginous substance, they will swim entire on the surface of the liquid in which they are intended to be given; and, if poured into the mouth in their original form, their pungency irritates the membranes of the mouth and throat, and occasions violent coughing. Much also is spilt in the struggle, and the horse will prove shy afterwards to take any thing that is forced upon him in the form of a drench. Rough substances, hot spices, ardent spirits, wines, powders, &c. produce this effect when they are not properly compounded; and Mr. Clark says he has frequently known pieces of solid gums, as large as a walnut, forced upon horses in a drench, in consequence of the prescriber's not knowing how to dissolve, or neglecting to reduce them to a powder. Venice or common turpentine, he observes, is frequently prescribed to horses with success, when *properly prepared*; yet, when these are administered without any other preparation than that of being reduced into a fluid state by the heat of the liquid in which they are given, they prove disagreeable, by sticking about the mouth and throat, and occasion violent coughing.—The same observation holds with respect to other remedies; and thus, by the injudicious compounding of drugs, the most powerful of them may be rendered of no effect; the poor animals fall a sacrifice to ignorance, and are deprived of that relief under their various diseases which it is in the power of medicine to afford, if properly administered.

“The proper time of administering drenches,” says Mr. Clark, “is likewise

of great importance; and, indeed, on this circumstance, in a great measure, depends their whole success in practice; for, however well adapted the compositions may be at a certain particular period of a disease, to remove or to mitigate it, yet, in certain cases, the very administering of medicines in the form of a drench proves hurtful, particularly when the throat, jaws, &c. are sore, swelled, and inflamed: the forcing a drench on a horse in this critical period is followed with the most violent symptoms: and it has frequently happened, that a simple solution of nitre in water, sweetened with honey or molasses, given in the above cases, has occasioned the most violent coughing, trembling, panting, &c. insomuch that the poor animals were like to drop down, merely from the acute pain they suffered from administering any thing by way of a drench in this critical period. The very position a horse's head is put in to receive a drench, in these cases, creates to him the most exquisite pain, from the distension the muscles of the throat, &c. undergo, when the head is held up by force, at a time when the animal can hardly bear these muscles to be touched by the fingers even in the gentlest manner.

“From what has been now observed, it will be evident how highly imprudent it is even to attempt the giving food or medicines by way of a drench in these cases, till such time as the swelling, inflammation, &c. are abated; and even then no medicines should be given but such as are of the emollient kind, and, at the same time, well blended with mucilaginous substances, as the infusion of linseed, solution of gum-arabic, or the yolks of eggs; as these substances blunt the pungency or sharpness of the drugs that are administered.

“As all herbs, seeds, &c. yield their virtues readily to water, they should be infused in that which is boiling, and the thin parts drained off for use; balsams should be incorporated with mucilages, gums should be powdered or dissolved, and all drenches should be made as agreeable as possible, and sweetened with molasses or honey.”

**DROPSY OF THE CHEST** is a disorder to which horses are subject; and many instances have occurred in the practice of the author, where seven, eight, and in one case near ten gallons of water were found in the cavity of the chest, upon opening the body after death. This ac-

cumulation of fluid being completely extravasated, no hope of cure can be entertained, as the preternatural collection can neither be taken up by absorption, or carried off by evacuation. There seems to be only one predominant trait, or distinguishing symptom, by which this disorder can be even tolerably ascertained, and that is solely by the action of the horse. In either walk, trot, or gallop, (and the more as his pace is increased in each) the fore legs seemingly spread from each other, as if they were internally distended by painful pressure, similar to division by forcible expansion, not at all unlike the means used by butchers in the stick pointed at each end to extend the limbs of carcases when displayed for sale. The legs in a trot constitute a painful hobble; and in a gallop the subject cannot get his legs before him, but appears at every motion likely to pitch upon his head. All this gives every reason to believe the defect, when first discovered, is frequently thought a lameness in the shoulder, and the patient immediately deemed a chest-foundered horse. If a horse having a dropsy in the chest, and the collection of water (from the duration of disease) is large, much information may be derived respecting the certainty, by the following experiment. Lead, or let him be rode up a gentle ascent, and he will be observed to move with but very little pain or impediment: the moment he is turned round, and descends, the weight of the water in the chest coming forward, and being pressed upon by the contents of the abdomen, in the action of going down hill, instantly produces so much pain, and such difficulty of proceeding, that with judicious practitioners, or nice observers, no great hesitation can arise in pronouncing the probable certainty of this disease.

DRUGS, a popular appellation denoting the various medicinal substances employed in the cure of diseases. Chemicals, as well as Galenicals, go under the general name of drugs. One of the crying sins of the age is, the adulteration of these, or the substitution of one substance for another. These frauds commence even in the country which produces the article; and it becomes more or less debased according to the number of hands through which it is conveyed to the unfortunate patient, whose life perhaps is the price of this detestable and most wicked practice. Mr. John Lawrence calls the attention of those who practice

veterinary medicine to the probable danger of the most judicious prescriptions, where the ingredients are defective, or not to be depended upon. The advantages of ready-made medicines (*i. e.* of drugs compounded pharmaceutically into balls, drinks, &c.) he says, are obvious enough; but it were to be wished there were less to counterbalance these: for, it must be acknowledged, the temptation of putting off bad drugs in these compositions is great, the hazard of their being stale considerable, and the uncertainty not a little in point of accuracy, where it may be reasonably supposed very large masses are compounded at one time. Instances, he says, are not wanting, where the distribution of the cathartic bases has been so irregular, that one ball has acted as a mere alterant, while another has nearly purged a horse to death. Nor, in these ready-made medicines, need we expect, where two kinds of the same article are to be had, any but that which is inferior; as in the instance of aloes, of which the Barbadoes is the cheapest and least favourable in its effects; and rhubarb, of which the Turkey is the best and the dearest.

From a little book, published under the auspices of that Duke of Devonshire who was the proprietor of Flying Childers, Mr. Lawrence transcribes the following general advice with regard to the purchasing of drugs for veterinary uses; first premising that the author complained much of the badness of the drugs purchased by the country apothecaries in his days, which he asserts were the worthless refuse of the London shops; and that he once had a horse killed by a farrier's drench.

1. *Chemical Preparations* should be had from the most eminent chemists in London, which, if kept well stopped in flint glasses, will be preserved good for many years.

2. *Woods and Gums*. Woods should ever be purchased in the piece: in chips they will not last good above a year; in powder only a few months. Preserve these in boxes of tin or oak, in a dry place.

3. *Seeds* ought to be fresh every year.

4. *Roots and Herbs*, if native, it is highly convenient to cultivate at home.—Herbs must be dried annually, roots preserved as directed for woods and gums.

A desideratum in veterinary medicine is the ascertaining, by direct experiment, the effects of the different articles of the materia medica upon brutes. For want of this we are led to employ, often at a great expense, medicines incapable of

acting at all, or perhaps in a very different degree, on those animals. Gibson, in his *Farrier's Dispensatory*, has included almost all the remedies prescribed in human diseases; but the experiments of modern veterinarians will probably reduce this list very considerably. When drugs must be had, it is prudent to purchase them at the most reputable shops, and rather to compound the articles ourselves than trust to balls, &c. sold in a prepared state.

**DUBBING.** Taking off the comb and gills from a game chick, before he is turned to a master-walk, is so called. The operation is performed with a penknife for the comb, and scissors for the gills; after which wash the parts with vinegar, or weak salt and water, which terminates the whole.

**DUCK, WILD.** Wild ducks frequent the marshy places in many parts of this kingdom; but no where in greater plenty than in Lincolnshire, where prodigious numbers are annually taken in the decoys. In only ten decoys in the neighbourhood of Wainfleet, as many as thirty-one thousand two hundred have been caught in one season.

Wild ducks are very artful birds. They do not always build their nest close to the water; but often at a good distance from it; in which case the female will take the young in her beak, or between her legs, to the water. They have been known sometimes to lay their eggs in a high tree, in a deserted magpie or crow's nest; and an instance has likewise been recorded of one being found at Etchingam, in Sussex, sitting upon nine eggs, in an oak, at the height of twenty-five feet from the ground: the eggs were supported by some small twigs, laid crossways.

**DULNESS,** in a horse of any tolerable spirit, may be considered an infallible sign of present disquietude, or approaching disease.

**DUN BIRD, or POCHARD.** This species, like the pintail, and some others, is common both to the old and new continent. With us it frequents the fens, as well as the coasts and tide rivers; in which last it is taken sometimes extremely fat in the severest weather. It is not ascertained whether they breed in England; but in France one has been shot in the month of July. Their food is small fish and shells: they are found south as far as Egypt, about Cairo, and in Carolina, during the winter. They have a hissing voice; their flight is more rapid than that of the wild duck, and the noise made by their wings is quite different; the flocks

observe no particular shape in flying, as the duck, in triangles, but form a close body.

The pochard is about the size of a widgeon, weighs one pound twelve ounces; its length is nineteen inches; breadth, two feet and a half; the bill is broader than the widgeon's, of a deep lead colour, with a black tip; irides, orange; the head and neck deep cheenut, with a small triangular spot of white under the centre of the lower mandible; the lower part of the neck and breast, and upper part of the back, dusky black; scapulars and wing coverts nearest the body, of a greyish white, elegantly marked with narrow lines of black; the exterior wing coverts and quills, dusky brown; secondary quill feathers regularly edged with a stripe of white; the belly, ash-coloured and brown; vent feathers, and coverts of tail, black; the tail consists of twelve short feathers, of a deep grey; the legs lead-coloured. The female has the head of a pale reddish brown; the breast is rather of a deeper colour; wing coverts and belly, cinereous; the back marked like that of the male.

These birds are eagerly bought by the London poulterers, under the name of dun birds, as they are deemed excellent eating: the greater part of what appear in the markets are caught in decoys.

**DUNG.** The excrement of the horse is so called, and should be occasionally observed, as its appearance will often indicate disease. If the dung is bright in colour, the globules uniform in shape and consistence, and not foetid in effluvium, the body may be considered in good state: on the contrary, if the dung, when voided, is hard, black, and offensive, or the parts adhere to each other by a viscid ropy slime, they are equal prognostics of internal heat, foulness, and impending disquietude. Horses in this state should be put under a course of physic without delay. On an accurate inspection of the dung, worms are sometimes seen in great plenty, although, from the general appearance of the horse, no such circumstance may have been suspected.

**DUNGANNON.** A bay horse, foaled in 1780, bred by, and the property of, Dennis O'Kelly, Esq. Dungannon was got by Eclipse, out of Aspasia, by King Herod; grandam, Doris, by Blank; great-grandam, Helen, by Spectator; great-great-grandam, Daphne, sister to Weasel, by the Godolphin Arabian, Fox, Childers, Makeless, &c.

On Wednesday, in the Newmarket Second Spring Meeting, 1783, Dungannon

BIRDS. *Plate III.*

GODWIT, *p.* 377.

won 65 gs. for 3 years old; colts, 8st. 2lb.—fillies, 8st. R. M. beating Mr. Golding's Billy, Mr. Vernon's Spot, Mr. Lade's Wilbraham, Sir F. Evelyn's Spinner, Sir J. Lade's Buzaglo, Lord Grosvenor's Inca, and three others:—5 to 4 on Dungannon, and 8 to 1 against Billy. On Saturday, at 8st. he beat Mr. Vernon's Embrio, 4 years old, 9st. 7lb. Ab. M. 100gs.—3 to 1 on Dungannon. At Epsom, May 29, he ran second (the first time of his being beat,) to Saltram, for the Derby stakes, beating Mr. Walker's Parlington, Duke of Queensberry's Gonzales, Col. O'Kelly's Cornet, and Mr. Davis's Phenomenon. At Grantham, June 19, he won the Rutland stakes, of 50gs. each, for 3 years old; colts, 8st.—fillies, 7st. 11lb. two miles, (8 subscribers) beating the Duke of Rutland's bay filly, by Herod, dam by Regulus—and Lord Grosvenor's bay colt, by Justice, out of the Flyer's dam,—Dungannon the favourite. Next day, at 7st. 4lb. he won a sweepstakes of 20gs. each, for all ages, two miles, (9 subscribers) beating Mr. Vernon's Drone, 6 years old, 9st. 6lb.; Lord Grosvenor's bay colt, by Justice, 3 years old, 7st. 4lb.; and Mr. Douglas's bay colt, by Herod, 3 years old, 7st. 4lb.—7 to 4 and 2 to 1 on the field. At Newmarket July meeting, at 8st. 2½lb. he received 60gs. from Mr. Gowland's Spinner, 7st. 11lb. Ab. M. 100gs.: next day, he won £50, with 20gs. added, for 3 years old; colts and fillies, 8st. each, the last mile and a distance of B. C. beating Mr. Davis's Buzaglo, Mr. Golding's Billy, Lord Egremont's Bonduca, Lord Grosvenor's Armida, Lord Clermont's Furioso, Duke of Queensberry's Pleasant, and two others:—3 to 1 on Dungannon, and 5 and 6 to 1 against Billy.

At Newmarket first spring meeting (on Tuesday), 1784, Dungannon won a sweepstakes of 100gs. each, h. ft. 8st. D. I. (6 subscribers,) beating Lord Clermont's George:—5 to 1 on Dungannon. On Thursday, he won a subscription of 25gs. each, for 4 years old colts, 8st. 7lb. D. I. (3 subscribers) beating Lord Grosvenor's bay colt, by Herod:—15 to 1 on Dungannon: next day, at 8st. he was beat by Mr. Bullock's Buzaglo, 8st. D. I. 200gs.:—7 to 2 on Buzaglo. On Wednesday, in the second spring meeting, at 7st. 2lb. he won the renewed subscription of 140gs. B. C. beating Lord Egremont's Mercury, 6 years old, 8st. 12lb. and Lord Clermont's Dictator, aged, 9st. 2lb.—7 to 4 on Dungannon, and 2 to 1 against Mercury. On Saturday, he beat Buzaglo, 7st. 7lb.

each, New Flat, 200gs.—3 to 1 on Dungannon. At Grantham, June 23, he won a sweepstakes of 10gs. each, with 20gs. added, for colts, 8st. 7lb.—fillies, 8st. 3lb. four miles (5 subscribers), beating Duke of Rutland's bay filly, by Herod, dam by Regulus:—3 to 1 on Dungannon: next day, he walked over for a sweepstakes of 10gs. each, with 20gs. added, four miles, (7 subscribers). At Nottingham, August 3, he walked over for £50, two-mile heats: next day, he walked over for a sweepstakes of 25gs. each, for colts, 8st. 7lb. twice round (12 subscribers). At Doncaster, September 29, he was beat by Sir J. Kaye's Phenomenon, for the gold cup, beating Mr. Crowle's Miss Rose.

At Newmarket first spring meeting (on Monday), 1785, Dungannon won the Craven stakes of 10gs. each, for all ages, 2 year olds, 6st.—3, 8st.—4, 8st. 9lb.—5, 9st. 1lb. A. F. (13 subscribers), beating Prince of Wales's Saltram, 4 years old; Mr. Wentworth's Mayfly, 5 years old; Mr. Bullock's Plutus, 5 years old; Mr. Naper's Punch, 4 years old; Sir J. Moore's Melon, 2 years old; Duc de Chartres's bay filly, by Prize, 2 years old; Duke of Grafton's Grasper, 2 years old; Mr. Wyndham's Partisan, 3 years old; Duke of Queensberry's Fortunatus, 4 years old; Lord Egremont's Brighton, 3 years old; and Duke of Northumberland's Young Denmark, 3 years old:—5 to 4 on Dungannon, 5 to 1 against Plutus, 8 to 1 against Brighton, 10 to 1 against Duc de Chartres's filly, and 12 to 1 against Punch. On Wednesday, he walked over for £50, D. C. In the second spring meeting, at 8st. 4lb. he won the renewed 140gs. B. C. beating Mr. Naper's Mountebank, 6 years old, 8st. 12lb.—10 to 1 on Dungannon. At Epsom, May 7, at 9st. he won the town purse of £50, two-mile heats, beating Lord Grosvenor's Roundelay, 3 years old, 6st.; Mr. Belson's Chance, 5 years old, 9st.; and Mr. Dutton's Mountebank, 6 years old, 9st. 4lb.—5 to 2 and 3 to 1 on Dungannon. At Burford, August 10, he won the king's purse, of 100gs. for 5 year olds, 9st. each, three-mile heats, beating Sir J. Lade's Punch, and Mr. Belson's Chance. On Wednesday, in the Newmarket second October meeting, he walked over for the 140gs. subscription, B. C. (7 subscribers): next day, at 8st. 5lb. he won 70gs. for all ages, B. C. beating Mr. Wyndham's Drone, aged, 9st.; Mr. Vernon's Harold, 4 years old, 7st. 4lb.; and Lord Grosvenor's Balance, 5 years old, 8st. 5lb. 7 to 4 on Dungannon. On Thursday, in

# D U N

the second October meeting, at 8st. he won 60gs. for all ages, D. I. beating Prince of Wales's Ulysses, aged, 8st. 6lb. and Lord Grosvenor's Latona, 6 years old, 8st. 4lb.—10 to 1 on Dungannon. On Saturday, he walked over a sweepstakes of 5gs. each (14 subscribers), B. C.

At Newmarket first spring meeting, 1786, Dungannon, 8st. beat H. R. H. the Prince of Wales's Rockingham, 7st. 8lb. B. C. 500gs.—2 to 1 on Dungannon. In the second spring meeting, at 8st. 12lb. He won the 140gs. subscription, B. C. beating Duke of Grafton's Oberon, 4 years old, 7st. 2lb.—7 to 2 on Dungannon. In the first October meeting, he won the king's purse, of 100gs. for 6 year old horses, &c. 12st. each, R. C. beating Lord Clermont's George, Mr. Hull's Quibbler, and Mr. Baldock's Fortunatus—3 to 1 on Dungannon. In the second October meeting, he won the whip, and 200gs. each 10 st. B. C. beating Mr. Wyndham's Drone, aged—Prince of Wales's Anvil, aged, paid —5 to 4 on Dungannon. The above were the only times of his starting. He was afterwards a stallion.

Dungannon covered at Epsom, Surrey, in 1788, 1789, at 26gs.; at Cannons, Middlesex, 1790, 1791, 1792, 1793, at 21gs.; 1794, 1795, 1796, at 16gs.; 1797, 1798, 1799, 1800, 1801, 1802, at 12gs. and a half; 1803, 1804, at 10gs. and a half. He died in 1808. He was sire of the following winners, viz.—

<i>Horses', &amp;c. Names.</i>	<i>Proprietors.</i>
Bandalore . . . . .	Mr. Corrie,
Bedford . . . . .	Lord Grosvenor,
Billy . . . . .	Mr. Cookson,
Boaster . . . . .	Mr. Golding,

besides several others.

Dungannon was grandsire of many capital racers, and from his blood have descended a great many of the best and most favourite horses of their years.

Aspasia (dam of Dungannon), bred by the Duke of Ancaster, was foaled in 1775. She was also the dam of Mr. O'Kelly's bay colt, Sergeant, by Eclipse, foaled in 1781, and H. R. H. the Prince of Wales's Cheyt Sing, by Eclipse or Vertumnus, foaled in 1786.

DYSENTERY, a violent purging, accompanied with blood in the stools. All fluxes of the belly, in horses and other cattle, are generally included under the names of a lax and scouring, or dysentery. When a horse falls a purging, and continues but a short space in it, or when he is more than ordinarily open, and dungs like a cow, it is called a lax; and when the purging continues, though it amounts to what we call a *diarrhœa* in men, he is only said to scour. As to a dysentery, when blood and slime come away with the excrements, it is a symptom that seldom happens, except when a horse has been wounded in the intestines, or has received some uncommon treatment, such as violent and repeated drastic purges; but it is seldom, if ever, the mere effect of a *diarrhœa*. That horses are not subject to dysentery, Gibson supposes, may be owing, in a great measure, to their horizontal position, whereby the rectum is less apt to be affected in severe purgations than it is in men. Besides, he observes, the violent gripings, that are almost always the concomitants of a *diarrhœa*, soon destroy a horse, if they are not removed: so that the disease seldom has time to arrive at the state of a dysentery or bloody flux. The remedies directed under *diarrhœa*, with some variations which will occur to the practitioner, may be rendered applicable to cases of dysentery.

# E

**EARS.** As the ears constitute much of the beauty of a horse, according as they are well or ill shaped, so from their situation, they are sure to become early objects of observation. If they are small, soft and fine, curving inward in a small degree at the point, perfectly erect, and spirited in action, they give the animal a very noble, majestic, and commanding aspect: on the contrary, when a horse points his ears forwards, he bears the appearance of looking eternally for mischief, and always preparing to start at every object he meets, which is no very pleasant sensation to the rider. Horses of this description have seldom good eyes. Horses having coarse, long, foul ears, set on too low, and hanging down on the sides, are called mule or lop-eared horses. The greater part of the racing stock of Old Herod, one of the best stallions ever bred in England, were foul, long, and wide in their ears, which is to be seen in almost the whole of their progeny.

Pain in the ear of a horse is discoverable immediately by its flaccidity, and painful deprivation of erection. The ear lays nearly flat either one way or another; the horse is almost every minute giving violent shakes of his head, which he as constantly leaves hanging down on the side affected; from which circumstances alone the seat of pain may with certainty be ascertained. Pains in the ear may arise from various causes, as colds, blows, the insinuation of, or sting from, forest flies, bees, wasps, or hornets. If the first is known to be the cause, the stimulus excited by mildly rubbing the inside with the half of a newly-divided onion, will soon relieve the pain. If from a blow, rubbing the ear inside and out with two table spoonsful of camphorated spirits, mixed with two tea spoonsful of extract of saturn, will relieve. If from a sting, a plentiful impregnation of fine olive oil, to give the skin the power of expansion, will be right in the moment of increasing inflammation; after which, the swelling may be allayed with common white wine vinegar, verjuice, or strong vegeto-mineral water.

Trimming the ears on the inside is a very common, but an injudicious, practice. Care should be taken never to let it be done during rainy weather, sharp and severe winds, or in the winter season; dreadful colds, as well as dangerous dis-

eases, have often been produced by these means. The operation of trimming should be performed in warm, open, mild weather, and with scissors in preference to the flame of a candle; which, with the additional use of the twitch, only serves to put the poor animal to a double degree of unnecessary misery. After the ears are trimmed, they may be rubbed over the inside with a small quantity of fresh butter, or a piece of fine linen impregnated with olive oil, both of which are excellent preventatives to cold after the operation.

**EARTH.** When a pursued fox takes refuge under ground, if it be in a sough, drain, &c. he is said to have *gone to ground*; but if he make his way into a regular earth, he is then said to have *gone to earth*.

**EARTH-STOPPER** is an indispensable part of a fox-hunting establishment, whose business is principally performed by night. His department is to visit and stop the strongest earths in the district intended to be hunted on the following day. This is usually effected between the hours of ten at night and four in the morning, by means of bushes, brambles, earth, &c. to furnish which, he is provided with a hand-bill, spade, candle and lantern, a hardy rough pony, terriers, &c. It is also his business to re-open the earths after the sport of the day, that the foxes may not fall victims to other modes of destruction.

**ECLIPSE** was bred by the Duke of Cumberland, of Culloden memory, and was foaled in 1764, during the great eclipse, whence his name. He was got by Marske, out of Spiletta, and might be said to unite the blood of the Darley and Godolphin Arabians. Eclipse was supposed to be a shade inferior in speed for a short distance to Flying Childers, but superior in powers of continuance, and consequently able to run greater lengths in a shorter space of time. Eclipse had considerable length of waist, and stood over a great deal of ground; his shoulder was thick, but wide and well placed; his hind quarters appeared higher than his fore-hand; in his gallop he went in the true racing form, and no horse ever, perhaps, drew up his hind legs so effectively; he possessed a vigorous constitution, uncommon strength, and was altogether the most complete racer that ever appeared, though he was thick winded, and breathed

hard when running: his colour, chesnut, with a white face and white hind leg.

At the decease of the Duke of Cumberland, he was purchased by Mr. Wildman, for 70 or 75 guineas. Some time afterwards, Mr. Wildman sold the half of him to Mr. O'Kelly for 650 guineas, and the latter gentleman ultimately purchased the other half for 1100 guineas. Eclipse did not appear upon the course until he was five years old. He won eleven king's plates, carrying 12 stone in all but one; and his proprietor acknowledged that he gained £25,000 by him. He was rather a sulky-tempered animal, but won every race in which he appeared without the application of either whip or spur, and was never distressed by the speed of a competitor. The progeny of Eclipse, in twenty-three years, produced to their owners the sum of £158,047: various prizes not included.

If we except Flying Childers, nothing has been seen on the turf that would bear a comparison with Eclipse. He may be regarded as the perfection of the race-horse; and, as in cases of a similar kind, the difficulty, if not impossibility, of continuing the pinnacle of perfection, may be easily perceived, from the circumstance, that, in defiance of every possible care and attention, a second Eclipse has never been produced.

The heart of Eclipse weighed nearly fourteen pounds, which is one-third heavier than what the same part is usually found. His form altogether, for motion and continuance, was superior to what has ever been witnessed, either before or since.

In 1769, when five years old, he won two 50gs. at Epsom; 50, at Ascot Heath; the king's 100gs. and 50, at Winchester; the 100gs. the bowl, and 30gs. at Salisbury; and the king's 100gs. at Canterbury, Lewes, and Lichfield.

In 1770, he received forfeit 600gs. and won the king's 100gs. at Newmarket; the king's 100gs. at Guildford; the same at Nottingham; the same, and 319gs. at York; the king's 100gs. at Lincoln; 150gs. and the king's 100gs. *again* at Newmarket, where, orders having been privately given by his owner, "to go off at *score*, and run the whole four miles for *speed*," he double-distanced his opponents, and was then taken out of training for want of a competitor. From this time he continued as a stallion at Epsom, in Surrey, and afterwards at Cannons, the seat of Colonel O'Kelly, in Middlesex, where he

died on the 27th of February, 1789, in the 26th year of his age.

He was sire of Firetail, Soldier, Corporal, Sergeant, Don Quixote, King Fergus, Nina, Charlemont, Competitor, Gunpowder, Hidalgo, King Hermon, Meteor, Pegasus, Scota, Serpent, Squeak, Stripling, Devi Sing, Eliza, Poor Soldier, Big Ben, Spitfire, Fair Barbara, Adonis, Mercury, Lily of the Valley, Volunteer, Bonnyface, Jupiter, Venus, Antiochus, Dungannon, Maria, Henley, Soujah ul Dowlah, Grimalkin, Dian, Thunderbolt, Lightning, Spinner, Horizon, Miss Hervey, Plutus, Pluto, and Comet; exclusive of a great number of winners.

EEL, THE. In the early ages of our history we find the eel considered as a rarity. Will. de Aislebury was invested with certain lands in Bucks, by William the Conqueror, under the singular tenure of providing straw for his bed and chamber, and three eels, for his use in winter.

Becket, about the year 1160, gave five pounds (equal nearly to fifty pounds of our present money) for a single dish of eels.

The eel (says Mr. Pennant) is singular in several matters relating to its natural history, and in some respects borders on the reptile tribe; the eel is known to quit its element, and, during the night, to wander along the meadows, not merely for change of habitation, but also for the sake of prey, feeding on the snails in its passage: during winter it beds itself in the mud and continues torpid like the serpent kind, is very impatient of cold, will eagerly seek shelter in a wisp of straw flung into a pond in severe weather; and which has sometimes been practised as a method of taking them. Albertus goes so far as to say that he has known eels, for warmth, betake themselves to a hay-rick; yet even there the excess of cold has destroyed them.

Mr. Arderon says, that in June 1746, while he was viewing the flood-gates belonging to the water-works of Norwich, he observed a great number of eels sliding up them, and up the adjacent posts, to the height of five or six feet above the surface of the water. They ascended with the utmost facility, though many of the posts were perfectly dry and smooth. They first thrust their heads and about half their bodies out of the water, and held them against the wood-work for some time; Mr. A. imagines until they found the viscosity of their bodies sufficiently thick, by exposure to the air, to

support their weight. They then began to ascend directly upwards, and with as much apparent ease as if they had been sliding on level ground: this they continued until they had got into the dam above.

The ancients adopted a most wild opinion about the generation of these fish, believing them to be either created from mud, or that the scrapings of their bodies, which they left on the stones, were animated and became young eels. As to their immediate generation, it has been amply proved to be effected by the ordinary course of nature, and that they are viviparous; many persons have convinced themselves of the fact, by opening and taking from the eel a small soft whitish substance, knotted curiously together: upon being put into water this has separated, and the young eels were perfect, and, though not bigger than a small thread, have swam about; this discovery always took place the end of summer, or beginning of autumn, and has been adduced as a confirmation of their going down to the salt water to spawn: those that remain in the rivers, or that have been carried by floods into rivulets and ditches, of which some are to be found at all times, produce their young in the same way.

It had been generally imagined that the eel had no scales until they were discovered by the microscope, when if the slime be wiped clean away, by the aid of that instrument, the skin will be found covered with exceeding small ones, ranged in a very orderly manner. To obtain these from the skin, take a piece of the skin which grows from the side of the eel, and while moist spread it on a piece of glass, that it may dry very smooth: when thus dry it will appear all over dimpled, or pitted by the scales, which lie under a sort of cuticle, this thin skin may be raised with the sharp point of a pen-knife together with the scales, which will then easily slip out. It has been asserted, from trials of this nature, that very few fishes, except such as have shells, are destitute of scales.

A very accurate and ingenious observer has thus mentioned his remarks upon the migration, &c. of eels.

There is (says this gentleman) one other fish common in this country that is migratory, when in a situation to admit of it: this is the eel. Eels can live and breed in stagnant ponds from which there is no outlet, as carp, tench, and several other fishes do; but whether they ever

there attain the same perfection as under other circumstances may, perhaps, be doubtful. In what place the eel deposits its young in preference to others, when at perfect freedom; or whether the young fry make a progression towards the sea, as the salmon does at a certain period of its growth, I cannot tell. But in one particular case I know, and it has been observed by others, that in the month of June, yearly, immense swarms of young eels make a progress from the lower part of the river towards the higher, with a quickness and unremitted assiduity that are surprising. This phenomenon was remarked in the river Dee, in Aberdeenshire. The eel is a fish that seems (unlike the trout) to dislike running streams, and therefore avoids that part of the river where the current is strong. It had probably been this circumstance that induced them, in the rapid Dee, to direct their progress only along the edges of the river close to the banks.

A line followed the windings of the river, being often suddenly deflected by stones or other interruptions without any breach of its continuity. This line having frequently caught my eye, my hand was put into the water to touch the line, with a view to examine what it was: the line became discontinued, when my hand approached; but it united again as soon as my hand was withdrawn. This induced a nearer examination; and I then perceived, with astonishment, that this line was formed by a series of small eels, moving forward with great celerity. These eels did not exceed half an inch in length, but were in all respects perfectly formed like the common eel. The line might, perhaps, on an average, consist of from twenty to thirty in breadth, and the individuals being in different degrees of forwardness, and close to each other, made the line uniform. The progress with which they advanced, was not less than four miles an hour: and this continued for eight days and nights together; and there was no apparent diminution of it when I left the place. There was a similar line on the opposite side of the river. The water in which they floated at the place where I observed them was in general about two or three inches deep.

From the above statement, it may safely be computed that the numbers which must have thus passed amounted to many myriads. What becomes of such multitudes of fishes we may conjecture, but

never, perhaps, shall be able to ascertain.

The above observations (continues this gentleman) respect the spontaneous movements of eels upwards in rivers; those that follow indicate their similar progress downwards at one season of the year. In Scotland, in the neighbourhood of Linlithgow, is a considerable lake, in which great quantities of eels are caught, by hooks and lines during any of the summer months; but the principal fishing is in the month of October, when it is found that the eels, directed by natural instinct, discover an irresistible propensity to issue from the loch by the passage through which the water flows from it to the sea. In October the person who rents the fisheries puts into that passage a kind of chest, so formed as to allow free passage to the water, while it stops those eels that exceed a certain size. This chest is every morning emptied of its fish, which are sometimes in such abundance as to require carts to carry them away. This fishing continues about a month; before or after which time few or none can be so taken; the chest is then removed, and the passage left free.

In Wiltshire, about Warminster, where the rivers are small and more rapid in their course than in many other parts of England, the mills placed on the streams are numerous, and the water is carefully directed into one channel. The persons possessing these mills having discovered that numbers of eels go down the river every flood, happening in October, have devised a box, which they call an eel grate; this is placed in a convenient part of the river, and thus great quantities of eels are caught. They also find, that no eels worth mentioning can be taken in this way at any other season of the year.

Whether the eels thus caught in descending the river are near the breeding time, as the salmon are which ascend the same small streams, has not been ascertained. Probably they are; if so, they are not, like the salmon, lean, but fat, and in good condition. It is probable that these eels, after depositing their young near the mouths of the rivers, ascend the rivers again at another season of the year, till they regain their former haunts, although there are not the same facilities for discovering their progress upward, were it even certain, as for that in their descent. They may have been at first entangled in their descent in baskets or nets whose mouths were placed towards

the current. This could not be done in their ascent; and although devices called cruives have been invented for catching salmon in ascending the rivers, yet the progress of eels in that direction having not been remarked, no contrivance for thus catching them has been devised.

It might be possible, by watching the time the large eels return, to devise contrivances for stopping them in their ascent, somewhat similar to the salmon cruives, which might be done at a trifling expense, upon those small rills especially that communicate with swamps or lakes; for though the banks were overflowed during floods, yet, if these eel-traps occupied the full width of the rill, when in its usual state, no loss could be sustained during floods, as the strength of the current would at that time interrupt their progress upwards. It is very probable, that if the large eels do return, they may do it more leisurely than they descend, especially where the water runs dead; therefore, in brisk running streams, we shall most likely discover the circumstances that affect these migrations.

The eel is placed by Linnæus in the genus of *muræna*, his first of the apodal fish, or such as want the ventral fins; the eyes are placed not remote from the end of the nose; the irides are tinged with red; the under jaw is longer than the upper; the teeth are small, sharp, and numerous; beneath each eye is a minute orifice—at the end of the nose, two others. The eel is furnished with a pair of pectoral fins, rounded at their extremities; behind which is the orifice to the gills, which are concealed in the skin; another fin on the back, uniting with that of the tail, and the anal fin, joins it beneath in the same manner.

Eels vary much in their colours, from a sooty hue, to a light olive green; and those which are termed silver eels, have their bellies white, and throughout a remarkable clearness. There is another variety of this fish, known in the Thames by the name of grigs, and about Oxford by that of grigs or gluts. These are scarcely ever seen near Oxford in the winter, but appear in spring, and bite readily, which the common eels in that neighbourhood will not: they have a bigger head, a blunter nose, thicker skin, and are less fat, than the common sort—are in less estimation, and seldom exceed three or four pounds weight. The black eel has a large head, a black back, and yellow belly; the flesh is reckoned un-

wholesome, especially when taken out of mud in standing waters. The Italians have the following proverb,—“ Give eels and no wine to your enemies.”

The common eel will grow to a large size, sometimes to weigh twenty pounds, but that is extremely rare; in 1799 one was taken out of the Kennet, near Newbury, which weighed fifteen pounds. Walton mentions one caught near Peterborough, which was a yard and three-quarters in length.

No fish lives so long out of water as the eel; so tenacious of life is it, that the parts will move a considerable time after they are flayed and cut into pieces.

They are extremely voracious, and most destructive to the spawn and small fry of fish; and Sir John Hawkins has spoken *feelingly* of their depredations not being confined to the young of *fish* only, for his broods of *ducklings* were all secured under water, by the large eels with which his canal abounded.

Congers differ from the common eel in the following particulars. Their colour in general is more dark; their eyes much larger in proportion; the irides of a bright silvery colour. The lower jaw is rather shorter than the upper. The side line is broad, whitish, and marked with a row of small spots—Mr. Ray says a *double* row. The edges of the dorsal and anal fins are black. They have more bones than the common eel, especially along the back quite to the head. As to the distinction that Mr. Ray and other writers make of the small beards at the end of the nose, it ought not to be depended upon, they being sometimes found in both kinds, and sometimes entirely wanting. They grow to a much greater size. Dr. Borlase assures us, that they are sometimes taken near Mount's Bay, of one hundred pounds weight. Some taken near Scarborough were ten feet and a half long, and eighteen inches in circumference at the thickest part.

Mr. Pennant believes that the congers generate like the fresh water species: innumerable quantities of what are supposed to be their fry, come up the Severn about the month of April, preceding the shads, which it is conjectured migrate into the river to feed on them.

Congers are extremely voracious, preying on other fish, and on crabs at the time they have lost their shell, and are in a soft state. They and eels in general are also fond of carcasses of any kind, being frequently found lodged in such as are accidentally taken up.

Mr. Pennant remarks, that a fishery of congers would be of great advantage to the inhabitants of the Hebrides. Perhaps they would at first undertake it with repugnancy, from their absurd aversion to the eel kind.

Mr. Barry in his history of the Orkney Islands, says, the conger which is about six feet long and one in circumference, frequents the seas around those isles, where it is often caught by lines set for other fishes, but much oftener by the otter, which drags it ashore, devours a part, and leaves the remainder to be picked up by carrion birds, or carried off by the country people. The common eel, continues Mr. B. is to be met with in all our brooks, lochs, and in the seas, and at certain seasons, in great plenty in the harbour of Stromness; the size is never large, seldom exceeding two feet and a half in length, and its thickness in proportion. The skin, which is of a tenacious nature, is stripped off, and worn to prevent the cramp; but the fish itself, though excellent food, is seldom brought to the table, on account of some antipathy which the people have to it.

The haunts of the eel are among the weeds, under roots, stumps of trees, in holes and clefts of the earth, both in the banks, and at the bottom in the plain mud, where they lie with only their heads out, watching for their prey; they are also to be found under great stones, old timber, about bridges, flood-gates, weirs, and old mills, except when the water is rendered thick by rains, for then they come out, and will bite eagerly. They are in best season from May until July: a running line should be used, which must be very strong, and the hook No. 3 or 4, with a plumb or pistol bullet upon it. They are to be angled for on the ground, and two or more rods may be employed: (if ground-bait be thought necessary, it should be the same as for the barbel:) the prime bait is the lob-worm, and they bite eagerly all day, in dark cloudy weather, after showers, attended with thunder and lightning, when the water is high and discoloured; but those who venture upon night angling, will have far greater success when the weather is warm and the night dark; they are then to be angled for upon the shallows, where there is a current, or by the side or tail of a stream, with a sandy or gravelly bottom, with the bait on the ground; they will be felt to tug sharply when they seize the bait; give time

(which is necessary both in day and night angling,) and there will be no doubt of sport from night-fall until day-break, when they directly flee to their hiding places.

The largest eels are caught by night-lines; it is of little consequence where they are laid, as they will succeed in streams (where the eels rove in search of prey) as well as in the still, deep holes of rivers; and they will take frogs, black snails, worms, roach, dace, gudgeons, minnows, (which two last are the best) loaches, bleaks, and miller's-thumbs. A sufficient quantity of links of twelve hairs should be doubled, and a hook tied to each link; these are to be noosed at proper distances to pieces of cord of fifteen feet long; bait the hooks by making an incision with the baiting-needle under the shoulder, and thrusting it out at the middle of the tail, drawing the link after it; the point of the hook should lie upright towards the back of the bait-fish; fasten one end to the bank or a stub, and cast the other into the water, but not to the extent of the line, (as eels will run a little before they gorge :) the lines should be taken up early in the morning; such of the lines as have eels at them will be drawn very tight. Dark nights in July, August, and September, are the best for this kind of fishing. Trimmers baited with a live gudgeon are sure to be taken by eels. The wire to which the hooks are fixed should be strong and well nealed, as the eel struggles hard to free himself. Lines, with from twelve to twenty hooks looped on at different distances, will do well in streams; but for standing waters, trimmers are greatly to be preferred.

Another method of taking eels when

the water is clear and low, is called snig-gling, and is performed with a stick about a yard long, with a cleft at each end, and a strong needle well whipped to a small whipcord line, from the eye down to the middle. In baiting, run the head of the needle quite up into the head of a lob-worm, letting the point come out about the middle; then put the point of the needle into the cleft at either end of the stick, and taking both stick and line together in one hand (some of the line being wrapped round the hand,) put the bait softly into holes under walls, stones, &c. where eels hide themselves; if there be an eel there, he will take the worm and needle out of the cleft; draw back the stick gently, (having slackened the line,) and give time for his swallowing the bait: then strike, and the needle will stick across his throat; let him tire himself with tugging, previous to any attempt to pull him out, for he lies folded in his den, and will fasten his tail round any thing for his defence. The largest eels are generally taken about the hollow stonework of old bridges, (the angler being in a boat) and are sometimes caught in considerable numbers.

A third plan for taking eels, is by what is termed bobbing, which see.

ELECAMPANE, a root formerly in much estimation for its efficacy in coughs and disorders of the breast and lungs; hence the reputation it has attained in pectoral compositions for the use of horses. The great difficulty, however, of procuring any thing like the genuine root in powder from the medical retail shops, must ever prevent any great gratification or expectation, to those who rely too much upon the properties it is said to retain.

**ELEPHANT.** Of all quadrupeds, this animal is the largest, as well as the strongest; and yet, in a state of nature, it is neither fierce nor formidable, if we except perhaps a certain periodical furor with which it is sometimes seized, when its inoffensive disposition seems, for a time, completely reversed. Mild, peaceful, and brave, it never abuses its power or its strength, and only uses its force for its own protection or that of its community. In its native deserts, the elephant is seldom seen alone, but appears to be a social friendly creature. The oldest of the company conduct the band; that which is next in seniority brings up the rear. The young, the weak, and the sickly, fall into the centre; while the females attend their young, and keep them from falling by means of their trunks. They maintain this order only in dangerous marches, or when they desire to feed in cultivated grounds: they move with less precaution in the forest and in solitudes: but without ever removing or separating so far asunder as

## E L E P H A N T

to be incapable of rendering each other any requisite assistance. Nothing can be more formidable than a drove of elephants as they appear at a distance in an African landscape ; wherever they march the forest seems to fall before them ; in their passage they bear down the branches upon which they feed ; and if they enter an enclosure they destroy all the labours of the husbandman in a very short time. Their invasions are the most disagreeable to the natives, as they possess no means of repelling them ; since it would require a small army to attack the whole drove when united. In their retreats, however, it now and then happens that one or two linger behind the rest, and it is against these that the art and force of the hunters are united ; but any attempt to molest the whole body would certainly be fatal. The Indians and Negroes, who are often incommoded by such visitants, do all they can to keep them away, make loud noises and large fires round their cultivated grounds ; but these precautions do not always succeed ; the elephants sometimes break through their fences, destroy their whole harvest, and even overturn their little habitations. When they have satisfied themselves, and trod down or devoured whatever lay in their way, they retreat into the woods in the same orderly manner in which they made their irruption. Should any one offer to impede their progress or molest them, they go forward against the intruder, strike him with their tusks, seize him with their trunks, fling him into the air, and then trample him to pieces under their feet. But they are thus dreadful only when offended, and seldom or ever offer the least personal violence when suffered to pass without interruption.

The Elephant is a native of Africa and Asia, but is found neither in Europe nor America. In Africa he still retains his natural liberty. The savage inhabitants of that part of the world, instead of attempting to subdue this powerful creature to their necessities, are happy in being able to protect themselves from its depredations. Yet they are taken in considerable numbers in some parts of this uncivilized part of the world, principally in pit-falls, for the sake of their teeth, which are regularly brought down to the coast and exchanged for European commodities. There, during the first journey of my much lamented friend, Mungo Park, into the interior of Africa, he remarked to some of the natives the domestication of this enormous quadruped, and the useful purposes to which his extraordinary powers were applied ; they laughed in his face, and exclaimed *tababo fonio* (a white man's lie). In Abyssinia elephant hunting is followed as a diversion, as well as for the animal's flesh, which is highly esteemed by the natives. Indeed the Africans in general are fond of the flesh of the elephant, the Hottentots regard it as one of the greatest dainties, with which, however, they are seldom gratified, as, of all the natives of this barbarous quarter of the globe, none are either so ignorant or so inactive as the Hottentots. At present there are no elephants found in the northern parts of Africa. It is beyond the river Senegal that they are to be met with in great numbers, and so down to the Cape of Good Hope, as well as in the heart of the country. In this extensive re-

## E L E P H A N T

gion they appear to be more numerous than in any other part of the world ; are less fearful of men, and appear as if conscious of the impotence and ignorance of the inhabitants which blacken this burning region of the world. The natives, however, take the elephant (as before observed) by means of pitfalls. Through the woody forests several paths are cut ; in which are dug deep and large holes, which are carefully covered over with branches and loose earth.

“ With slender poles, the wide capacious mouth,  
And hurdles light, they close ; o’er these is spread  
A floor of verdant turf, with all its flow’rs  
Smiling delusive, and from strictest search  
Concealing the deep grave that yawns below.  
Then boughs of trees they cut, with tempting fruit  
Of various kinds surcharged ; the downy peach,  
The clust’ring vine, and of bright golden rind  
The fragrant orange. Soon as ev’ning grey  
Advances, slow besprinkling all around  
With kind refreshing dews the thirsty glebe,  
The stately elephant, from the close shade,  
With step majestic, strides ; eager to taste  
The cooler breeze that from the sea-beat shore  
Delightful breathes, or in the limpid stream  
To lave his panting sides ; joyous he scents  
The rich repast, unweeting of the death  
That lurks within. And soon he sporting breaks  
The brittle boughs and greedily devours  
The fruit delicious.—Ah ! too dearly bought ;  
The price is life. For now the treacherous turf  
Trembling gives way ; and the unwieldy beast,  
Self-sinking, drops into the dark profound.”

But although these animals are most plentiful in Africa, it is in Asia that the largest elephants are found : in the former place, they seldom exceed ten feet in height, while in the latter they are frequently seen from twelve to fifteen.

The wild elephants of Ceylon live in troops or families, distinct and separate from all others, and seem to avoid the strange herds with particular care. When a family removes from one place to another, the largest tusked males put themselves at the head ; and, if they come to a river, are the first to pass it. On arriving at the opposite bank, they try whether the landing place is safe : if it is, they give a signal with their trunk, on which another division of the old elephants swim the river : the younger then follow, supporting each other by locking their trunks together ; and the rest of the old ones bring up the rear.

At Tepura, in the East Indies, elephant hunting is followed as a source of profit, or, in other words, many are here caught for the purpose of reducing them to obedience, and afterwards to employ them as beasts of burden or labour. As the hunters know the places where the elephants come out to feed, they advance towards them in the evening with four komkees, (the number of which each hunting party consists.) When the nights are dark, the male elephants are discovered by the noise they make in cleaning their food, which they

## E L E P H A N T

do by whisking and striking it against their fore legs ; and in moonlight nights may be seen distinctly at some distance. As soon as the hunters have determined on the animal they mean to secure, three of the komkees are conducted silently and slowly, at a little distance from each other, near to the place where he is feeding. The komkees (trained female elephants) advance very cautiously, feeding as they go along, and appear like wild elephants that have strayed from the forest. When the male perceives them approaching, if he takes the alarm and is viciously inclined, he beats the ground with his trunk and makes a noise, shewing evident marks of his displeasure, and that he will not allow them to approach nearer. In this case, if they persist, he will immediately attack and gore them with his tusks ; for which reason they take care to retreat in good time. He, however, generally allows them to approach, and sometimes even advances to meet them. The drivers now conduct two of the females, one on each side, close to him, and make them press themselves gently against his neck and shoulders ; the third female then comes up and places herself across his tail. In this situation, far from suspecting any design against his liberty, he begins to toy with the females and caress them with his trunk. While thus engaged the fourth female is brought near, attended by proper assistants, furnished with ropes, who immediately get under the belly of the animal at the tail, and put a small rope round his hind legs. If he takes no notice of this slight confinement, the hunters proceed to tie his legs with a stronger rope, which is passed alternately, by means of a forked stick and a kind of hook, from one leg to the other, in the form of a figure of 8. Six or eight of these ropes are generally employed one above another, and they are fastened at their intersections by another rope that is made to pass perpendicularly up and down. A strong cable with a running noose, sixty cubits long, is next put round each hind leg, above the other ropes ; and afterwards six or eight other ropes are crossed from leg to leg above the cable. Fixing these ropes generally occupies about twenty minutes, during which time the utmost silence is observed.

The komkees now retire to a little distance, and the animal attempting to follow them, and finding his legs tied, immediately becomes sensible of his danger, and makes, as fast as he can, towards the jungle. The hunters, mounted on the tame elephants, accompanied by a number of people, who till this time have been kept out of sight, follow him at a little distance, and as soon as he passes near a tree sufficiently stout to hold him, they take a few turns with the long cable, which trailed behind him, round its trunk. His progress being thus stopped, he becomes furious, and exerts his utmost efforts to disengage himself. The komkees dare not now come near him ; and in his fury he falls down on the earth, and tears it up with his tusks. In these exertions, he sometimes breaks the cables and escapes into the thick jungle. Hither the hunters dare not follow him for fear of the other wild elephants ; and are therefore obliged to leave him to his fate. This, however, seldom happens ; and when he has exhaust-

## E L E P H A N T

ed himself by his exertions, the komkees are again brought near and take their former positions, one on each side and the other behind. After getting him nearer the tree, he is more securely fastened :—his fore legs are now tied in the same manner as his hind legs were; and cables are made fast, one on each side, to trees, or stakes driven deep in the earth.

As soon as he has become more settled, and will eat a little food, the komkees are again brought near, and a strong rope is then put twice round his body, close to his fore legs like a girth, and tied behind his shoulder; the end is then carried backward close to his rump, and there fastened, after a couple of turns more have been made round his body. Another rope is next fastened to this, and thence carried under his tail like a crupper, and brought forward and fastened to each of the girths. A strong rope is now put round his buttocks, and fastened on each side to the girths and crupper, so as to confine the motion of his thighs and prevent him from taking a full step. A couple of large cables, with running nooses, are now put about his neck, there secured, and tied to the ropes on each side. Thus completely hampered, the cables round his neck are made fast to two komkees, one on each side.—Every thing being now ready and a passage cleared from the jungle, all the ropes are taken from his legs, except the strong one round his buttocks to confine the motion of his hind legs, which is still left. The komkees pull him forward; sometimes, however, not without much struggling and violence on his part. When brought to his proper station and made fast, he is treated with a mixture of severity and gentleness; and generally in a few months becomes tractable, and perfectly reconciled to his fate. It seems somewhat extraordinary, that though the animal uses his utmost force to disengage himself when taken, and would kill any person coming within his reach, yet he seldom or never attempts to hurt the females that have ensnared him; but, on the contrary, seems (as often as they are brought near in order to adjust his harnessing, or move or slacken those ropes which gall him) pleased, soothed, and consoled by them, as it were, for the loss of his liberty.

The mode of securing a herd of wild elephants is very different, as well as more tedious, than that adopted in the capture of a single male.

A herd of elephants generally consists of from forty to a hundred; and when it is intended to take a whole herd, as soon as it is discovered, about five hundred people are employed to surround it. By means of fire and noises, the hunters are, in the course of some days, able to drive them to the place where they are to be secured. This is called the Keddah. It consists of three inclosures, communicating with each other by means of narrow openings or gateways. The outer one is the largest, the middle the next in size, and the third or furthestmost the smallest. When the animals arrive near the first inclosure (the palisades and gates of which are as much as possible disguised with branches of trees and bamboos stuck in the ground, so as to give them the appearance of a natural jungle) great difficulty attends the business of getting them in. The leader always suspects

## E L E P H A N T

some snare, and it is not without the utmost hesitation that he passes ; but as soon as he enters all the rest implicitly follow. Immediately when they have passed the gateway, fires are lighted round the greater part of the inclosure, particularly at the entries, to prevent the elephants from returning. The hunters from without then make a terrible noise by shouting, beating of tomtoms (a kind of drum), firing blank cartridges, &c. to urge them on to the next inclosure. The elephants, finding themselves entrapped, scream and make other noises ; and discovering no opening except the entrance to the next inclosure, they at length, but not before they have many times traversed round their present situation, following their leader, enter it. The gate is instantly shut upon them, fires are lighted, and the same discordant noises made as before, till they have passed through another gateway into the last inclosure, where they are secured in a similar manner. Being now completely surrounded on all sides, and perceiving no outlet through which they can escape, they appear desperate, and in their fury advance frequently to the surrounding ditch in order to break down the palisade, inflating their trunks and screaming out aloud : but wherever they make an attack, they are opposed by lighted fires, and the noise and triumphant shout of the hunters. The ditch is then filled with water, and after a while they have recourse to it in order to quench their thirst and cool themselves, which they do by drawing the water into their trunks, and then squirting it over every part of their bodies.

After the elephants have continued in the inclosure a few days, where they are regularly, though scantily, fed from a scaffold on the outside, the door of the Roomie (an outlet of about sixty feet long and very narrow) is opened and one of the elephants is enticed to enter by having food thrown before it. When the animal has advanced far enough to allow it, the gate is shut and well secured on both sides. Finding his retreat now cut off, and the place so narrow that he cannot turn himself, he advances and exerts his utmost efforts to break down the bars in front of him, running against them, screaming and roaring most violently, and, battering them, like a ram, with repeated blows with his head, retreating and advancing with the utmost fury. In his rage he even rises up and leaps upon the bars with his fore feet, striving to break them down with his huge weight. When he becomes somewhat fatigued with these exertions, ropes are, by degrees, put round him ; and he is secured in a manner nearly similar to that adopted in taking the single males. And thus, in succession, they are all secured.

The newly-captured elephants are now separated, and each put under the care of a keeper, who is appointed to attend and instruct him. A variety of soothing and caressing arts are practised : sometimes the keeper threatens and even goads him with a long stick pointed with iron ; but more generally coaxes and flatters him, scratching his head and trunk with a long bamboo, split at one end into many pieces, and driving away the flies from his sores and bruises. In order to keep him cool, he likewise squirts water all over him ; carefully

## E L E P H A N T

standing out of the reach of his trunk. In a few days he advances cautiously to his side, and strokes and pats him with his hand, at the same time speaking to him in a soothing voice ; and, after a little, the animal acknowledges the authority of his keeper, and obeys his commands with a sagacity which cannot fail to astonish and please. While they are training in this manner, the tame elephants lead the others out alternately, for the sake of exercise, and likewise to ease their legs from the cords with which they are tied, and which are apt to gall them, unless they are regularly slackened and shifted.

In five or six weeks the elephant becomes completely obedient to his keeper, his fetters are taken off by degrees ; and in a little time he suffers himself to be conducted from one place to another.

Tavernier, in his travels in India, tells us that he was present at the taming of two of these animals :—“ After two hours’ travel, we came to a great village, where we saw the two elephants that had been lately taken ; each of these was placed between two tame ones. Round the wild elephants stood six men, each with a half pike in his hand, with a lighted torch fastened to the end of it, who talked to the animals, giving them meat, and calling to them in their own language ‘ *take it, take it.*’—If the wild elephants refused to do as they were bid, the men made signs to the tame ones to beat them, which they did thus :—one of them banged the refractory elephant about the head with his trunk, and if he offered to make any resistance the other thwacked him on the other side, so that the poor animal, not knowing what to do, was at length constrained to become obedient.”

It has been asserted that the sagacity of the elephant is so great, and his memory so retentive, that, when once he has received any injury, or been in bondage and afterwards escaped, it is not possible, by any art, again to entrap him. The following instances, however, recorded in the Philosophical Transactions of the Royal Society for 1799, will prove that such is not the case : A female elephant was first taken in the year 1765, by Rajah Kishun Maunnich ; who, about six months after gave her to Abdoor Rezah, a man of some rank and consequence in the district. In 1767, the Rajah sent a force against this Abdoor Rezah for some refractory conduct, who, in his retreat to the hills, turned the above-mentioned beast loose in the woods, after having used her two years as a riding elephant. She was afterwards re-taken, but broke loose in a stormy night, and again escaped. In the year 1782, about ten years after her second escape, she was driven by the elephant hunters belonging to Mr. Leek, of Longford Hall, in Shropshire, into the inclosure in which the elephants are secured ; and the day following, when Mr. Leek went to see the herd that had been taken, this elephant was pointed out to him by the hunters, who well recollected her. They frequently called to her by name, to which she seemed to pay some attention by immediately looking towards them when it was repeated ; nor did she appear like the wild elephants, which were constantly running about the inclosure in a rage, but seemed perfectly reconciled to her situation. For the space of eighteen days she never went near

## E L E P H A N T

enough the outlet to be secured—from a recollection perhaps of what she had twice before suffered. Mr. Leek at length went himself when there were only herself, another female, and eight young ones remaining in the inclosure. After the other female had been secured by means of the komkees, the hunters were ordered to call on her by name. She immediately came to the side of the ditch within the inclosure; on which some of the hunters were desired to carry in a plaintain tree, the leaves of which she not only took from their hands with her trunk, but opened her mouth for them to put a leaf into it, which they did, caressing her and calling her by name. One of the trained elephants was now ordered to be brought to her, and the driver to take her by the ear and order her to lie down. At first she did not like the komkee to go near her, and retired to a distance seeming angry: but when the drivers, who were on foot, called to her, she came immediately and allowed them to stroke and caress her as before; and in a few minutes after, permitted the trained elephants to be familiar. A driver from one of these then fastened a rope round her body, and instantly jumped on her back, which, at the moment she did not like, but was soon reconciled to it. A small cord was then put round her neck for the driver to put his feet in; who, seating himself on the neck in the usual manner, drove her about the inclosure in the same way as any of the tame elephants. In short she was so obedient, that, had there been more wild elephants in the inclosure, she would have been useful in securing them.

In June, 1787, a male elephant taken the year before, was travelling in company with some others, towards Chittigong, laden with baggage; and having come upon a tiger's track, which elephants readily discover by the smell, he took fright, and ran off to the woods, in spite of all the efforts of his driver. On entering the wood, the driver saved himself by springing from the animal and clinging to the branch of a tree under which he was passing. When the elephant had got rid of his driver, he soon contrived to shake off his load. As soon as he ran away, a trained female was despatched after him, but could not get up in time to prevent his escape. Eighteen months after this, when a herd of elephants had been taken, and had remained several days in the inclosure, one of the hunters, viewing a male elephant very attentively, declared he resembled the one which had run away. This excited the curiosity of every one to go and look at him; but when any person came near, the animal struck at him with his trunk, and in every respect appeared as wild and outrageous as any of the other elephants. An old hunter at length coming up and examining him, declared that he was the very elephant that had made his escape. Confident of this, he boldly rode up to him on a tame elephant, and ordered him to lie down, pulling him by the ear at the same time. The animal seemed taken by surprise, and instantly obeyed the word of command, uttering at the same time a peculiar shrill squeak through his trunk, as he had formerly been known to do; by which he was immediately recognised by every person acquainted with this peculiarity.

Elephants, when hunted, endeavour to avoid muddy rivers with the greatest care, probably that they may not stick fast in the ooze; while, on the other hand, they industriously seek out the larger rivers which they swim over with the greatest ease. For, notwithstanding that the elephant, from the form of his feet and the position of his limbs, does not seem to be adapted for swimming (when he is out of his depth in the water, his body and head being entirely sunk under the surface;) yet he is in much less danger of being drowned than many other land animals, as he carries his long trunk raised above the surface of the water in order to breathe, and can steer his course in it by means of this appendage. It has consequently been observed that when several elephants have swam over the river at the same time, they have all found the way very well; and have been able also to avoid running foul of each other, though their heads and eyes have been all the while under water.

The elephant, during the rutting season, is seized with a madness which makes him utterly untractable, and renders him so dangerous that it is often necessary to kill him. A wild elephant will sometimes stray from the herd, become solitary and mischievous, and will kill any person who happens to come in his way. On such occasions, the inhabitants of India go out against him in great numbers, well armed; but he seldom falls till he has received many bullets—sometimes an almost incredible number.

**EMBROCATION**, a name given to spirituous, volatile, or saturnine applications in a liquid form; either as corroborants, stimulants, repellents, &c. and in most cases they are doubly efficacious, if their use is preceded by sponges dipt in a hot decoction, prepared from those garden aromatics called “fomentation herbs.”

**EMOLLIENTS**, medicines which diminish the force of cohesion in simple solids, and therefore soften and diminish the hardness and rigidity of the parts to which they are applied. They not only relax and supple the solids, but also sheathe and soften the asperity of the fluids.

Emollient topics are formed of water, with oily and mucilaginous substances.—Water, particularly when assisted by a moderate heat, is plentifully absorbed from the whole surface of the body. It powerfully relaxes and dilutes, being miscible with almost every animal fluid. Oil relaxes and obtunds what is acrid; and mucilage also sheathes sharp humours.—In compositions of this kind, the aqueous part should be freely allowed, for the mucilages require to be largely diluted; gentle friction on the part increases their efficacy, and, as to the heat with which they are applied, it should not exceed

what produces a pleasing sensation.—From the relaxing quality of emollient topics, and their sheathing of acrimony, it is that they are good sedative applications, when pain from tension, or from irritation, is excited: from the sympathy of the nerves, their efficacy is conveyed also to distant and deep-seated parts; and thus it is that the warm bath proves so powerful a sedative.

**ENTRANCE OF HORSES**, is the ceremony of entering horses (at the particular places appointed) on a certain day previous to the races at any city, borough, or town, where the plates to be run for are given and advertised.

**ENTRANCE OF HOUNDS**, is the introduction of young hounds to the pack, with whom, at a proper age, they are incorporated, for their initiation in the kind of chase to which they are then to become appropriated.

**EPILEPSY**, a disease which occurs in various animals. A horse in the epilepsy reels and staggers, his eyes are fixed in his head, he has no sense of what he is doing, stales and dungs insensibly, runs round, and falls suddenly, sometimes immoveable, with his legs stretched out, as if he were dead, except only a very quick motion of his heart and lungs, which makes him work violently at his flanks,

and sometimes an involuntary motion and shaking of his limbs. At the going off of the fit, he generally foams at the mouth; the foam is white and dry, like that which comes from a healthy horse when he champs upon his bit.

It is common in the cure, first of all to bleed; but, if the horse be low in flesh, or has come off any hard journey, or is old, this should be sparingly done. Indeed, it is altogether improper in the majority of cases: as the epilepsy is usually a disease of debility, and not, as in the apoplexy, occasioned by plethora.

The following ball may be administered, with a proper drink to wash it down:

Take of Assafoetida, half an ounce,  
Castor, pounded, two drachms,  
Venice turpentine, the same quantity,  
Diapente, one ounce,  
make them into a ball with honey, adding

Oil of amber, one drachm.

The drink is to be made as follows:

Take of Pennyroyal,  
Mistletoe, of each a large handful,  
Valerian root, one ounce,  
Liquorice, half an ounce,

boil them in a quart of water; let it be poured off, and administered after the ball.

Let this be repeated, sometimes once, sometimes twice, a-day at first, and afterwards once in two or three days. Purges and clysters at proper intervals, to keep the body open, and prevent a relapse.

EQUERRY is an appointment in the home department of the king, under the sole direction of the master of the horse. There are five equerries, one of whom is called the first: of the other four, two are always in waiting to attend upon his majesty in every equestrian excursion, whether on the road, to the field, or in the chase.

EQUITATION. See HORSEMANSHIP.

ESCAPE. The name of a horse of great beauty, excellent symmetry, and much celebrity. He was bred by Mr. Franco, and got by Highflyer out of a Squirrel mare; he was foaled in 1785; and in the first spring meeting at Newmarket, 1789, he beat the Prince of Wales's Cantoo Baboo, over the Ditch-in, for 200 guineas. He was then purchased by his Royal Highness, and in the second spring meeting he received forfeit from Alexander and Clown, 100 guineas each. In the first October meeting of the same

year, he beat Nimble across the flat, 200 guineas. The Craven meeting, 1790, he beat Grey Diomed over the Beacon, 500 guineas; and won the great subscription purse at York, beating Actæon and Gustavus. The Craven meeting, 1791, he beat Skylark, Highlander, Glaucus, Hal-kin, Meteor, and Buffer, a subscription of 50 guineas each: two to one on Skylark. First October meeting the same year, he beat Grey Diomed over the Beacon course, 8st. 7lb. each, for 1000 guineas. Two days after, he beat him again for the renewed 140 guineas. In the second October meeting, he won a subscription purse (twelve subscribers) over the Beacon, beating Chanticleer, Skylark, Grey Diomed, Harpator, and Alderman, with the odds four and five to one against him. When taken out of training, he covered at Highflyer Hall at ten guineas a mare, and half-a-guinea the groom.

ESCHAR. A hard crust or scab upon the flesh, formed by the application of a red-hot iron, a caustic, or some sharp application to the body.

ESTRAY, OR STRAY. Any horse, or head of cattle, which having strayed from its own home into a strange manor, or lordship, and there found without an owner, is then called an estray, or stray: in which case it is an established custom, sanctioned by law, that such stray is proclaimed, and his or her marks described, by the common crier, in the three next nearest towns on the market-day; and if the stray is not claimed within a year and a day of the time on which it was publicly cried, and fully described, it then becomes the property of the lord of the manor where it was found. If the owner makes the claim within the time limited, he is liable to pay reasonable charges for finding, keeping, proclaiming, &c. An estray must be kept without labour, uninjured, and properly fed, till reclaimed, or the time above-mentioned is expired.

EVACUANTS. Such medicines as, by their stimulus, augment the excretions of the body. Thus purgatives, sudorifics, diuretics, &c. may be called evacuants.

EVACUATION. Any diminution of the animal fluids, whether it be by cathartics, blood-letting, or any other means.

EXERCISE. By exercise I mean only in regard to such horses as are allowed to stand too much at rest in the stable, and at the same time are full fed, and breathe constantly a hot foul stag-

nated air in close stables; the whole of what is here advanced being calculated to promote the health and soundness of horses, by recommending such precepts as may contribute to preserve them in a proper habit of body, and render them fit for active exercises, in order that they may perform them with ease and freedom to themselves, and with pleasure to their owners. At the same time, it will show how much it is the interest of those who keep horses, and wish to have them in health, &c. to attend particularly to this important article.

It will perhaps appear strange at first view, to assert that a much greater number of horses who are high fed, and stand much at rest in close warm stables, die of diseases which are brought on them from the want of regular exercise, especially in great towns, than from any other class of diseases to which they are liable.

Horses are formed for labour. Inactivity renders them unfit for it; and, at the same time, it is hurtful to their health, in a variety of respects.

Inactivity, with full feeding, renders the body dull and sluggish. The stomach is loaded with food, which it cannot properly digest. The food is detained too long in the bowels. Hence indigestion, costiveness, and flatulencies. The intestines, in this loaded state, press upon the surrounding viscera, and obstruct the circulation of the different fluids in them. The liver, mesentery, and spleen, are exposed to be injured from this cause; their natural functions are impeded; the animal economy is disturbed; and, when this is the case, the constitution must be injured, and diseases ensue. The natural secretions are not in due quantity; they, together with the perspiration, are retained in the body, and are absorbed or taken up again into the mass of humours. And hence arises another source of disease. The circulation of the blood, through the whole system, is slow and languid. Hence the humours or juices are not properly prepared; glandular obstructions are formed in different organs of the body; the sheath and legs swell; running sores take place in the latter, commonly called grease; and the whole mass of fluids are greatly disposed to putrefaction; diseases follow, and death frequently concludes the scene.

On the other hand, constant and habitual exercise renders the body strong and active, and, at the same time, fit for the most violent exercises. All animals,

when left to themselves, are directed by natural instinct to use exercise. Young animals, in particular, show a strong propensity to it; and the very nature and constitution of a horse requires a considerable proportion of exercise at all times of life.

Exercise acts as an assistant to the heart, in promoting a free circulation of the blood and juices through every part of the body. It creates an appetite, and promotes digestion, and thereby greatly assists in converting the food to nourishment. It promotes all the secretions and excretions, which enlivens the body, and gives room for fresh supplies of nourishment; it invigorates the whole system; it gives a flow of spirits, and adds firmness and strength to the muscles and sinews. In short, without a certain proportion of exercise, no animal body can enjoy health.

The motion of the body, or what is called muscular motion, causes the blood and juices to circulate freely through every part. As this motion continues or increases, the breathing becomes quicker and shorter, and the perspiration is forced out at the pores of the skin. The sweat then becomes visible on the surface of the body, in the form of steams, like smoke. The wetness on the skin sometimes resembles froth, and is sometimes thin and watery, according to the habit of body the horse is in at the time. The sweat of a fat horse is always clammy, and of a frothy appearance; that of a thin meagre habit, when in good condition for exercise, is thin and watery.

The constant and habitual use of exercise or labour increases the firmness of the muscular fibres, which, being thereby more closely compacted, the serous or watery parts of the fluids are more expressed from their interstices, by which they acquire a degree of rigidity, that causes, as it were, a dryness of the whole muscular parts. Hence the difference is very visible to the eye, between the firmness of the flesh of post, running, and hunting horses, and those that are fat, and little used to labour or exercise.

The effects of exercise to horses are not only beneficial to their health, but, at the same time, it keeps them in that condition which is necessary to preserve them in proper order for performing the various labours which may be required of them: besides, in many cases of beginning disorders, its good effects soon become visible, when it is used as a medi-

cine, in those horses who have swelled legs, &c. from standing idle in the stable. For, although such horses may have been declared full of humours, and that nothing could relieve them from these supposed humours, but purging, diuretic, or alterative medicines; yet it has been frequently found, that regular exercise, frequent rubbing of the legs, with a roomy stall to stretch their legs when they lie down, have removed these complaints, without any medicine whatever.

It has already been observed, that, in great towns, most horses that are kept there are much injured for want of regular exercise. They stand in the stable, pampered to the full with the richest food, for days, nay even for weeks, together, without going any farther than the water, and frequently even that is carried to them. Hence their stomachs are filled and over-loaded with gross food. This produces a crude indigested chyle, which vitiates the blood, and disposes it to disease. Rides, or covered shades, for exercising horses in all weathers are extremely useful; and no stable-yard, in large towns, should be without them; although, at the same time, the open air is preferable to too close shades, or riding houses.

I remember to have somewhere read of a fact that seemed to have all the marks of authenticity, and which is applicable to the present subject, the substance of which is as follows:—The governor of a fortress on the continent having been unexpectedly shut up in his garrison, by the enemy, at a time when he had admitted a considerable body of cavalry of his own party on their march. In such a situation, the cavalry were looked upon as lost; but, to the amazement of those who saw them when the siege was raised, they were not only in health, but in excellent order, and fit for the most active exercises. The method the governor ordered them to be treated was thus: As he had no room to exercise them but in the stable, which was bomb proof, he ordered three men at a time to each horse; one to get on his back, the other two were stationed on each side behind him, with long whips in their hands, they were ordered to make the horse stir about from side to side, till such time as he was covered with sweat; the men, when tired, were succeeded by others. Others again were ordered to rub the horse down till he was quite dry. This manœuvre was repeated every day; which afforded exercise both to men and horses,

and preserved both from those diseases which arise from inactivity.

From what has been said, it will appear how salutary, and even necessary, regular exercise is, in preserving horses in health. From the same reasoning, it likewise may be inferred, that they should be accustomed to labour and active exercises by degrees; for all sudden changes, whether from idleness to active exercises, or from those exercises to idleness, produce considerable changes in the system, and render both the solids and fluids liable to disease. This we experience from our feelings. When a man, who has not been accustomed to undergo much fatigue performs any violent exercise or labour of any kind, by which he has been overheated and fatigued, while he is warm he feels no complaints; but, when he cools, he will feel himself stiff, and all over pained in the muscular parts; but if he perseveres in the daily use of the same exercise or labour, it becomes at last familiar to him, so that he can perform these exercises with ease to himself, and at the same time he will be free from those pains in the muscular parts which were at first occasioned by exertions to which they had not been accustomed. It is the same with horses, on their being first set to hard labour, or violent exercises, although they cannot express their feelings; yet the stiff contracted steps, upon moving them about, after a hard day's work, fairly discover that this is the case with them. Accustom them regularly to the habitual practice of these exercises or labour, it then becomes easy to them, without any stiffness or difficulty of breathing following from it. Hence, when a horse has arrived at this state or habit of body, he is then said, in the stable phrase, to be in wind.

EXPEDiate implies the cutting out the central ball of the foot of a dog, or such claws as shall totally prevent his pursuit of game. In earlier times, when the forest laws were more rigidly enforced, the owner of any dog not expediated, living within the district, was liable to a fine for non-obedience.

EXTRAVASATION, applies only to such fluids as may, from any accidental cause, or injury sustained, escape from the tubes or vessels in which they were confined; when they, from such extravasation, become stagnant, laying the foundation of an obstruction terminating in an enlargement, probably disagreeable to the eye, and some impediment to action. Ex-

travasated lymph, oozing from ruptured fibres, lay almost invariably the foundation of almost every tumefaction to which we can advert.

**EYE.** The organ of vision, through the means of which objects are represented to the mind. The eye is retained in the cavity termed the orbit by a variety of appendages, all essential to its welfare and economy.

The eye-lids of the horse are composed of a mixture of membranous and cartilaginous substances, and these terminate on their edges in a firm cartilaginous body, called tarsus. The tarsus is extremely vascular, and its vessels are attached to what are denominated the ciliary ducts, secreting a fluid for the purpose of moistening and lubricating the surfaces of the tarsi, and thereby preventing such consequences as otherwise constant friction would be apt to produce. When the tarsi become diseased, matter or pus is discharged, instead of the usual healthy liquor: in this state, excoriations of the neighbouring parts, and temporary adhesions of the eye-lids, may be expected. Two muscles, the elevator palpebræ and the orbicularis, perform the offices of opening and closing the eye-lids. The eye-lids of the horse are not so plentifully furnished with hair, termed the lashes, as those of the human subject; they are few and scattered, yet they fully serve to protect the eye from insects or other extraneous particles. The internal part of the eye-lids is covered by a thin, fine, vascular membrane, the tunica conjunctiva. This coat is reflected over the whole of the front of the ocular globe; here it ceases to be vascular almost entirely, and acquires a high degree of transparency, particularly in the centre of the eye. This transparency, however, is diminished or destroyed when the conjunctiva is diseased. As the tears contain a considerable portion of salt, they would be constantly producing irritation on the tunica conjunctiva, did not this membrane secrete a mucus to defend it from such an effect.

The lachrymal gland is situated at the outer corner and superior part of the eye. It has five, and sometimes six, excretory ducts, which convey the tears over the surface of the eye, by the puncta lachrymalia; they enter the ductus ad nasum, and are thence carried to the nose. The puncta lachrymalia of the horse's eye are much larger in proportion than they are found in the human subject. The horse has no lachrymal sac; and the ductus ad

nasum is osseous as far as the tubernated bones, where it becomes membranous, and terminates near the extremity of the nostril.

The tears are designed to preserve the transparency of the eye, to wash off extraneous matter, and to prevent any ill consequences from the friction between the cornea and the palpebræ. The lachrymal gland of the horse differs from that of the human subject, in not possessing a voluntary power, or being subject to the emotions of the mind. In the human eye, the lachrymal gland is frequently diseased; it may have its action morbidly increased, as in the epiphora, or watery eye: this seldom occurs with the horse; when it does take place, however, it is occasioned by inflammation.

At the inner corner of the eye of the horse is placed a cartilaginous body, no resemblance to which is to be met with in the human subject. This is the membrana nictitans, vulgarly called the haw. In the eyes of many birds we find a similar appendage, and what may with more accuracy be denominated a membrane, for it is really so; whereas, in the horse, this part is entirely composed of cartilage. Birds have a muscle for the sole use of directing the motions of this substance, horses have none. Whenever the eye is inflamed, it is drawn into the orbit by the retractor muscle; and the haw, being prevented from accompanying it by the bones of the orbit, seems to pass over about one half of the surface. If, by any motion of the eye, it be drawn to the internal corner, the membrana nictitans will have the appearance of covering the whole.

The eye is composed of three coats and three humours: some veterinarians acknowledge the existence of four coats, by the cornea forming two, the transparent and the opaque, which may be separated by maceration. The transparent cornea of the horse is large in proportion to that of the human subject: this circumstance endues him with a superiority of vision in the night. On removing the transparent cornea, the aqueous humour escapes, and the iris appears. The iris is a muscular curtain of an annular figure, having a hole in the middle, termed the pupil, and dividing the anterior part of the globe of the eye into two chambers: these are occupied by the aqueous humour. The pupil in the human eye appears black; but in the horse's eye it is of a blueish cast. The aqueous humour gives a convexity to the eye, refracts the rays of light, and en-

ables the pupil to perform its office. The pupil of the horse is horizontal, of some other animals perpendicular, of the human subject it is circular. The iris regulates the quantity of light that should pass through the pupil; and, when the former contracts, the latter is enlarged, and *vice versa*. A peculiarity in the eye of the horse is, his having several small, black, glandular bodies; the office usually ascribed to which is, their more effectually excluding the admission of light.

On removing the iris, the second humour, viz. the chrySTALLINE lens, makes its appearance. This is retained in its situation by a coat called its capsule, between which and the lens, a quantity of fluid has been discovered, termed by anatomists the liquor Morgagni (from the anatomist who first made the discovery), and supposed to be intended to prevent an immediate contact of the parts. The chrySTALLINE lens, in health, is transparent: its structure is such that the outer parts are soft, and become more and more firm as we approach towards the centre.

The use of the chrySTALLINE lens is to afford, by the refraction of light, a focal point on the retina.

The ciliary processes are a continuation of the choroid coat. In order to embrace the chrySTALLINE lens, they are thrown into plaits or folds. Their use is to oblige all the rays of light to pass immediately through the lens. Some animals, as fish, have no ciliary processes.

The third humour of the eye is the vitreous. This fluid is not contained in one general bag or chamber, but in numerous minute cells, resembling those of the orange, and of an admirable transparency. This humour is of the consistence and appearance of the purest water.

The vitreous humour serves to produce a small degree of refraction in the rays of light, and occupies and distends the posterior part of the globe of the eye.

The caruncula lachrymalis of the horse differs from that of the human subject, it being much less vascular. Its situation is between the two puncta: it is vascular only where it comes in contact with the tears, which it directs into the puncta. It is partially covered by the conjunctiva.

The diseases of the eye of the horse, though not very numerous, are by no means easily removed. Their usual situations are the tunica conjunctiva and the transparent cornea. Inflammation very frequently makes a sudden attack on these

parts, attended with a partial and violent determination of blood, an overflowing of the tears and protusion of the membrana nictitans: the light produces an irritating and painful sensation. This state of disease is occasionally periodical, and it is then vulgarly termed moon-blindness.

1. *Ophthalmia, or Inflammation of the tunica conjunctiva.* This begins in the most vascular part of the conjunctiva, then extends to that portion covering the sclerotic coat, and from thence proceeds to the transparent cornea.

When this is the case, the animal's eye-lids drop, the tears run plentifully over the cheeks, and still more pass through the nasal duct, where drops of fluid may be seen at its extremity, which never are seen in the healthy state of the eye; the haw is drawn over the eye, in order to prevent the admission of the rays of light, which, in this state of the eye, would irritate it, and increase the disease. It is not unusual, however, to find the eye that was to-day very much diseased and inflamed, quite clear in the course of the next day. This phenomenon is owing to the power of restoration being in the horse so great in comparison to what is in the human subject.

Mr. Feron justly observes, that this disease is never found in unbroken horses, but always in those that are domesticated. It is neither found in colts nor in old horses, but takes place at the age of between five and six. The reason, he thinks, is, that, at a period when the animal has ceased to grow, and may be said to have arrived at maturity, he is much more subject to plethora, and consequently to inflammatory diseases, than at any other period.

The great cause of ophthalmia in horses is the change of temperature to which they are exposed; not to mention the air they breathe, vitiated by their dung and urine fermenting in the stable. Hence it is that we find more horses with diseased eyes in London than in any part of the country (the cavalry excepted). Unequal exercise also contributes to produce this and almost all other inflammatory diseases; for it is very frequent to see horses exercised and ridden very violently one day, and suffered for a whole week afterwards to remain at rest.

"We are not," says Mr. Feron, "to consider this complaint as local; for, when it is so, it is much easier of cure: but constitutional, and therefore also requiring constitutional remedies and treat-

ment: but, unfortunately, we have not yet discovered a specific of this nature. The animal seldom perspires in this disease; and, if he does, it is in excess, which shows that the constitution is affected; and there is also a slow lingering fever. If he is bled, purged, &c. the eye first affected soon becomes clear; but, at the end of five or six weeks, the other eye becomes inflamed: this gets also clear; and, about the same period afterwards, the eye that was originally inflamed, now again becomes affected, and so on periodically, till the patient is totally blind in one of them. The degree of inflammation is very various; sometimes it is so great that the iris becomes affected, and a little deposit of lymph may be observed at its edge, and also at the edges of the little glandular bodies. This does not take place in the human subject; for, though the iris is contracted, it is in consequence of sympathizing with the retina to prevent the admission of the rays of light. This deposit of lymph is most commonly at the inner angle of the iris, and at the edge of the superior glandular bodies, and it is a sure indication of a succeeding cataract and blindness; and, as it is a deposition on the iris, it is very difficult to get rid of. The cornea is sometimes as red as if it had been washed with venous blood, and neither the iris nor the pupil can at all be seen.

It frequently happens that the iris appears of a yellow colour: this, however, does not indicate any disease in it, but shews an incipient disease of the cornea, which now receives more serum into its vessels than they can make transparent, because they are too much distended and enlarged to produce that effect; just as any coloured fluid will not appear transparent if contained in a glass tube of an increased diameter. These circumstances will also apply to the disease going off, as well as in its incipient state."

Mr. Feron's idea, that "this disease may be considered as a gouty inflammation of the eyes, peculiar to the horse," appears to us somewhat speculative, since it seems to resemble the gout merely in being a *periodical* disease. It is not, he insists, of the same specific character in diseases that affect the eye of man, of the ox, the sheep, or even the ass, which so much resembles the horse in other things. "In a number of cases the inflammation is periodical, and blindness is sure to ensue, though not always in both eyes; for, when one eye becomes blind, the other

frequently remains well: and therefore farriers employ the cruel mode of taking out one eye to save the other, which is sometimes attended with success, by the inflammation that is produced acting in the same way that a rowel or seton would do."

The treatment of ophthalmia in the horse is confined entirely to bleeding, purging, and diuretics; fomentations of warm water, in order to diminish the irritation from the tears that run over the cheeks; wholesome diet, and moderate but continual exercise, to increase perspiration.

2. *The Cataract.* "The most common and general termination of this specific ophthalmia," Mr. Feron observes, "is in the cataract. This is nothing more than an opacity of the crystalline lens, which was before transparent; it generally becomes of a white or yellow colour, &c. and inclining to white in the circumference: sometimes the capsule of the lens becomes thickened, and even bony, &c. an example of this kind is kept in the museum of the Veterinary College.

At other times, the lens escapes from its capsule, and adheres to the iris, which comes in contact with the cornea; the vitreous humour becomes absorbed, and the posterior part of the eye filled with lymph, the size of the eye being diminished. But if there is no lymph thrown out, then the cavity of the vitreous humour remains, and a septum is formed between it and the lens.

When the lens or crystalline humour gets loose out of its capsule, if it does not adhere to the iris, it rolls about the eye like a marble, and produces absorption of the vitreous humour, retina," &c. See CATARACT.

3. *Matter formed by the iris* is another, and not unfrequent, disease of the horse's eyes. In this case the purulent fluid gravitates to the depending part of the anterior chamber of the eye, and has a semi-circular appearance, on account of the figure of the cornea, the pupil being always contracted. If this matter is not soon removed, it will, by pressing on the cornea and iris, produce blindness: we ought, therefore, as soon as it is perceived, to puncture the edge of the cornea, just below the matter, with the point of a lancet, so as to allow of its escape. This appearance is almost always the forerunner of a cataract.

4. *Gutta Serena.* This disease is vulgarly called "glass-eyes" by farriers, be-

cause the eyes, far from being dull or disfigured, generally appear very clear and glassy. It is a much more frequent affection of the human eye than of that of the horse. The pupil is very much enlarged and dilated, in consequence of the total loss of sensibility in the retina and optic nerve; which being no longer capable of stimulating it to action, the muscular fibres contract from the centre towards the circumference, enlarging the aperture as when the perfect eye is exerting its powers to view objects in the dark. The gutta serena is supposed generally to arise from an affection of that portion of the brain immediately connected with the optic nerve; but it is more likely that the deficiency is confined to the nerve itself. Some diseases of the brain, as the staggers, or a blow on the head, will produce it. When proceeding from any of these causes, we may attempt the cure by bleeding, purging, blistering the top of the head, and stimulating the nostrils (Mr. Feron says) with the vapour of vitriolic or marine acid.

5. *Watery Eyes.* This complaint, as its name indicates, proceeds from an increased secretion of tears, which flow down the cheeks, in consequence of the lachrymal ducts not being capable of carrying all the superfluous quantity away; or it may arise from an obstruction of the nasal duct.

If the secretions from the lachrymal glands become inordinate, either from this cause, or from mere debility, which may render them too obedient to common stimuli, bracing and sedative collyria, such as those prepared with saturnine or other metallic salts, seem to promise the greatest advantage, without having recourse to means calculated to act on the system. But, when the watery eye is found to proceed from an obstruction of the ductus ad nasum, "the passage must be opened by injecting a decoction of linseed, or any other glutinous injection: if this fail, the ductus ad nasum must be opened with an instrument, introduced with great dexterity from the eye down to the nose."

6. *External Injuries of the Eye.* An inflammation produced by wounds or contusions of the eye-lid may extend to the eye itself; though few such accidents will occasion a loss of sight, if properly treated. In such cases, there is often a complete opacity for a time; but, on removing the inflammation, the cornea generally recovers its transparency. In violent acci-

dents, indeed, where wounds have extensively divided the coats of the eye, or where the eye has been ruptured by a contusion, vision, of course, is completely and irretrievably destroyed.

Mr. Denny advises us, whether the inflammation arise in consequence of injuries to the eye itself, or to the eye-lids only, to observe the following treatment:

Take away four or five pints of blood from the neck-vein, and apply the following poultice to the eye:

Take of Bread, finely grated, a handful;

Lead-water, enough to make it of a proper consistence; add

Olive oil, one ounce;

mix them. Apply it cold; renew it several times daily; and give the following ball, with mashes of bran and warm water:

Take of Barbadoes aloes, one ounce;

Ginger, in powder, two drachms; form them into a ball with treacle.

A low diet being required, hay and corn must be sparingly allowed. If the inflammation does not subside by the third or fourth day, a rowel put under the jaw, and continued till the disease be removed, is a suitable remedy.

After the above ball has operated, Mr. Denny directs the following fever-ball to be given morning and night:

Take of Antimonial powder, one scruple;

Nitre, in powder, six drachms;

Aniseeds, half an ounce;

Treacle, sufficient to form the ball.

It is not uncommon, he observes, for small specks to remain on the cornea after the inflammation is removed. "In such cases, the best application is a few drops of the tincture of opium, on lint, introduced between the eye-lids once or twice in the day. This stimulates the lymphatics to absorb the lymph; which, being diffused between the coats of the eye, occasions imperfect vision."

The state of the eyes in every horse constitutes so much of the value and excellence in respect to their good or bad formation, that proper, nay, extreme, circumspection ought to be used in the examination previous to purchase. The best and most experienced judges of horses are sometimes seriously disappointed, and not unfrequently deceived, in a superficial survey, and too hasty decision: in fact, there is no point of the animal upon the merits of which (in a variety of instances) it is so difficult to form

an accurate, at least an infallible, opinion, as upon the parts before us. If at first sight you are attracted by their bright, bold, prominent appearance, and observe they are sufficiently clear and transparent to reflect your own figure in the eye as you stand before it, and the horse neither winks, blinks, or rolls the orbs of the eyes about, as if feeling for the light when brought out of the stable, there is then every well-founded reason to believe they are not only safe, but perfectly good. On the contrary, when the eye appears flat, as if sunk in its orbit, with a palpable vacuum round the orb, between it and the eye-lid, it is a very unfavourable indication; particularly if there should be no defluxion from the eye, to justify the idea

of a temporary injury having been sustained by a blow, bite, or some such accident, neither to be foreseen nor guarded against. If there is a palpable indentation above the orbs, and a wrinkled contraction of the eye-lids towards the forehead, they are invariable symptoms of something wrong.

A small pig-eye should be likewise carefully avoided, as they are seldom to be depended upon; the subject is frequently addicted to starting, and the future state of the eye in general doubtful. A cloudy muddiness within the outer humour of the eye, (giving it an opaque appearance) or a milky thickening of the surface, denote present defect, and great probability of approaching blindness.

## F

**FALCONER.** A falconer, whose province it was to tame, manage, and look after falcons, and other hawks, was formerly as great and conspicuous a character as the most celebrated huntsman of the present day. The influence of fashion, and the changes wrought by time, have, however, very much obscured both sport and sportsman.

**FALCONRY.** I cannot but lament that the noble, the royal, diversion of Hawking, should have so much declined, as to be known in this country by little more than the mere name. As a diversion, it was far superior to the net, which was practised at the same period; and it is doubtful even, if the pleasure of the fowling piece is equal to that which was derived from the flight of the well-trained hawk. In remote antiquity, the kings of Persia and other eastern monarchs, as well as noblemen, followed, if not the same diversion, at least something nearly allied to it. In these countries, the eagle was taught to fly at the antelope, the gazelle, and the stag; while in Europe, the stronger kinds of hawks were trained to strike the hare, and the lesser used for feathered game. In some parts of the East, I believe, it is still practised; but in England, if the science of Falconry is not altogether forgotten, the breed of hawks best calculated for the purpose is as nearly as possible extinct. An eyrie or two may still be found perhaps in Scotland, and one still remains, I believe, in some part of Northumberland; but as these birds are unwelcome visitors to the farmer, they are not likely to increase, as they are not, as formerly,

protected by law: it is true, the statutes for this purpose remain; but, as hawking has been almost laid aside, they can be regarded in no other light than as a dead letter. Immense sums were formerly given for a cast of hawks; and, in the reign of Edward III. it was made felony to steal one of these birds. To take its eggs, even in a person's own ground, was punishable with imprisonment for a year and a day, together with a fine at the king's pleasure.

Falconry constituted one of the principal amusements of our ancestors: and a person of rank scarcely ever went abroad without a hawk on his fist: indeed, in such estimation was the diversion of hawking held amongst the great all over Europe, that Frederic, one of the Emperors of Germany, condescended to write a treatise upon the subject.

The hawks chiefly used for this diversion were the gyr-falcon, the falcon, the lanner, the sacre, the hobby, and the merlin. These are called long-winged hawks, to distinguish them from the baser kinds, such as the kite, buzzard, &c. which are neither so swift, so bold, nor so susceptible of that attachment to their keeper which distinguish the generous kind before mentioned.

The gyr-falcon is the largest of this fierce tribe; and next to him the falcon properly so called, of which there seems to be some variety, principally distinguishable under the heads falcon-gentil and peregrine-falcon, both, however, about the size of the raven. Next follows the lanner, the sacre, the hobby, and last of all

the merlin. The last of these may be frequently seen in this country in winter : its plumage is very beautiful, the wings and back are ash-coloured blue, and the throat yellow spotted with black ; in size it scarcely equals the cuckoo ; but its courage is equal, if not superior, to the gyr-falcon itself. It retires, on the approach of spring, to the northern parts of the continent, where it breeds. All these birds, indeed, may be found on the continent, and the falcon, properly so called, is still to be met with in Scotland ; but is generally distinguished by the appellations of the falcon and the tassel ; these, in fact, are nothing more than the male and female of the same species : the tassel is the female, and is, at the same time, the larger and the fiercer, in direct opposition to the general rule, but which, however, is found to be the case throughout the hawk and eagle tribes, if it do not prevail uniformly in all the rapacious kinds of birds.

But, notwithstanding the pleasure to be derived from the amusement of hawking, one very weighty reason may be stated for its decline, independant of the general introduction of the fowling-piece, viz. the trouble and expence attached to the rearing, training, and keeping these birds in order. It is true, the office of king's falconer still exists, and with a salary of more than one thousand pounds per annum ; yet there is little probability of the nobleman who receives it being often called upon to produce such ensigns of his office.

Falconry began about A. D. 450, continued a favourite amusement, and was cultivated as a liberal art so late as the fifteenth and sixteenth centuries. The office of grand falconer of England is hereditary in the Duke of St. Alban's, as that of master of the game is in the Duke of Grafton. The salary attached to the office is 982*l.* 10*s.* per ann. and 30*l.* each lunar month, making together 1372*l.* 10*s.* but, from various deductions, it does not net above one thousand pounds a year. The consequence annexed about the year 942 to the falconer of Howel Dha, Prince of Wales, we gather from the rules of his household, and we have every reason for believing (with the exception of a few national peculiarities) that these regulations were formed upon the same model as those of England. Among the twenty-four great officers of the Welsh court, the fourth was the great falconer, and he was limited to three draughts only of strong liquor at the royal table, lest intoxication should make him neglect his hawks. When this cour-

tier succeeded in his sport, the prince rose to meet him, and sometimes held his stirrup.

The mode of training a hawk is, in the first place, to put a cap of leather, called a hood, on the hawk's head the moment he is taken. It is so constructed as to prevent him from seeing, but to allow him to feed.

Slips of light leather, seven or eight inches long, and a quarter of an inch wide, are to be made fast to each of his legs. These are called jesses, and are to be fastened to a small swivel, fixed to the end of a thong of leather, three or four feet long, called a leash, so as easily to be detached from the swivel when the hawk is required to fly.

He is also to be equipped with two light bells, fastened to his legs by pieces of soft leather ; by the sound of which, when he is lost, we may be assisted in recovering him.

The hawk is now to be taught to come to the lure ; it is a forked piece of wood, covered with the wings of birds, and heavy enough to prevent the hawk from flying away with it. Pieces of meat are tied to each side of the lure, and it is attached to a string three or four feet long, by which it may be swung round in the air, or thrown to a distance.

The hawk is to be fed upon the lure, being first made to come to it when held very near him, then, when held a little farther off ; it is to be next thrown upon the ground to a small distance, and thus he is to be brought by degrees to fly to it, and to seize it eagerly, however far it may be thrown.

An assistant is now to swing the lure at some distance from the falconer, who casts off the hawk.

It is to be thrown into the air when the hawk is flying towards it, but so that he cannot attain it until it falls to the ground, lest he should be hurt by striking it in its flight.

When this lesson has been repeated, until the hawk has become eager to take the lure, the assistant is to swing it as before, but is to take it into his hand when the hawk is coming ; he is then to swing it again as soon as the hawk has passed ; and finally, to throw it upon the ground, when the hawk is returning towards him.

In this way the hawk will soon be taught to fly round the falconer, bending his flight inwards when the lure is shown to him, or when he hears the call of the falconer, who should always halloo when he

is luring. He may thus be made to follow the falconer wherever he pleases; this is called waiting on.

When the hawk has alighted upon the lure, the falconer is to walk round him, whistle to him while he is feeding, and reward him with a good meal when he is taken up.

It is thus that hawks are made obedient to the lure, and that they are exercised when they cannot be flown at game, but they must not be kept too long upon wing, or they would acquire the habit of flying low; and it is the perfection of a slight falcon to soar as high as possible.

It is now time to enter him to his game. While the hawk is waiting on at a proper height, his head being turned inwards—a partridge tied to a creance is to be thrown up; and when the hawk has taken it, he must be allowed to eat it on the ground near the falconer, who is to walk round him, and whistle to him as usual.

When this lesson has been repeated three or four times, by throwing up partridges not confined by the creance, the education of the hawk may be considered as completed; and he may be taken into the field.

**FALLOW-DEER, THE.** No two animals can be more nearly allied than the stag and the fallow deer. Alike in form, alike in disposition, in the superb furniture of their heads, in their swiftness and timidity; and yet no two animals appear more distinct, or avoid each other with more fixed animosity. They are never seen to herd in the same place, they never engender together, or form a mixed breed: and even in those countries where the stag is common, the buck seems to be entirely a stranger; in short, they both form distinct families; which, though so seemingly near, are still remote: and although with the same habitudes, yet retain an unalterable aversion. The fallow-deer, as they are much smaller, so they seem of a nature less robust, and less savage, than those of the stag kind. They are found but rarely wild in the forests; they are in general bred up in parks, and kept for the purpose of hunting, or of luxury, their flesh being preferred to that of all other animals. It need scarce be mentioned, that the horns of the buck make its principal distinction, being broad and palmated; whereas those of the stag are in every part round. In the one, they are flattened, and spread like the palm of the hand; in the other, they grow like a tree, every branch being of the shape of the stem that bears it. The fallow-deer also has the tail longer, and the hair lighter than the stag; in other respects, they pretty nearly resemble one another.

The horns of the buck, as of all other animals of this kind, are shed every year, and take the usual time for repairing. The only difference between it and the stag is, that this change happens later in the buck; and its rutting time, consequently, falls more into the winter. It is not found so furious at this season as the former; nor does it so much exhaust itself by the violence of its ardour. It does not quit its natural pastures in quest of the female, nor does it attack other animals with indiscriminate ferocity: however, the males combat for the female among each other; and it is not without many contests, that one buck is seen to become master of the whole herd. It often happens also that a herd of fallow-deer is seen to divide into two parties, and engage each other with great ardour and obstinacy. They both seem desirous of gaining some favourite spot of the park for pasture, and of driving the vanquished party into the coarser and more disagreeable parts. Each of these factions has its

FALLOW DEER,

## F A L L O W - D E E R

particular chief; namely, the two oldest and strongest of the herd. These lead on to the engagement; and the rest follow under their direction. These combats are singular enough, from the disposition and conduct which seem to regulate their mutual efforts. They attack with order, and support the assault with courage; they come to each other's assistance, they retire, they rally, and never give up the victory upon a single defeat. The combat is renewed for several days together; until at length the most feeble side is obliged to give way, and is content to escape to the most disagreeable part of the park, where only they can find safety and protection.

The fallow-deer is easily tamed, and feeds upon many things which the stag will refuse. By this means it preserves its venison better: and even after rutting, it does not appear entirely exhausted. It continues almost in the same state through the whole year, although there are particular seasons when the flesh is chiefly in esteem. This animal also browses closer than the stag; for which reason it is more prejudicial among young trees, which it often strips too close for recovery. The young deer eat much faster and more greedily than the old; they seek the female at their second year, and, like the stag, are fond of variety. The doe goes with young about eight months, like the hind; and commonly brings forth one at a time: but they differ in this, that the buck comes to perfection at three, and lives till sixteen; whereas the stag does not come to perfection till seven, and lives till forty.

As this animal is a beast of chase, like the stag, so the sportsmen of the old school have invented a number of names relative to him. The buck is the first year called a fawn; the second, a pricket; the third, a sorel; the fourth, a sore; the fifth, a buck of the first head; and the sixth, a great buck: the female is called a doe; the first year a fawn; and the second, a tegg. The manner of hunting the buck is pretty much the same as that of stag-hunting, except that less skill is required than in the latter. The buck is more easily roused; it is sufficient to judge by the view, and mark what grove or covert it enters, as it is not known to wander far from thence; nor, like the stag, to change its layer, or place of repose. When hard hunted, it takes to some strong hold, or covert, with which it is acquainted, in the more gloomy part of the wood, or the steep of the mountain; not like the stag, flying before the hounds, nor crossing, nor doubling, nor using any of the subtleties which the stag is accustomed to. It will take the water when sorely pressed, but seldom a great river; nor can it swim so long, nor so swiftly, as the former. In general, the strength, the cunning, and the courage of this animal, are inferior to those of the stag; and consequently it affords neither so long, so various, nor so obstinate a chase.

As the buck is a more delicate animal than the stag, so also it is subject to greater varieties. We have in England two varieties of the fallow-deer, which are said to be of foreign origin. The beautiful spotted kind, which is supposed to have been brought from Bengal; and the very deep-brown sort, that are now so common in several parts of the kingdom. These were introduced by king James I.

from Norway; for having observed their hardiness, and that they could endure the winter, even in that severe climate, without fodder, he brought over some of them into Scotland, and disposed of them amongst his chases. Since that time they have multiplied in many parts of the British empire; and England is now become more famous for its venison, than any other country in the world. Whatever pains the French have taken to rival us in this particular, the flesh of their fallow-deer, of which they keep but a few, has neither the fatness nor the flavour of that fed upon English pasture.

However, there is scarce a country in Europe, except far to the northward, in which this animal is a stranger. The Spanish fallow-deer are as large as stags, but of a darker colour, and more slender neck: their tails are longer than those of ours, they are black above, and white below. The Virginian deer are larger and stronger than ours, with great necks, and their colour inclinable to grey. Other kinds have the hoof of their hind legs marked outwardly with a white spot; and their ears and tails much longer than the common. One of these has been seen full of white spots, with a black list down the middle of his back. In Guiana, a country of South America, according to Labat, there are deer without horns, which are much less than those of Europe, but resembling them in every other particular. They are very lively, light of course, and excessively fearful; their hair is of a reddish fallow, their heads are small and lean, their ears little, their necks long and arched, the tail short, and the sight piercing. When pursued, they fly into places where no other animal can follow them. The Negroes stand to watch for them in narrow paths which lead to the brook where they drink, or the meadow where they feed; there waiting in the utmost silence (for the slightest noise will drive them away) the Negro, when he perceives the animal within reach, shoots, and is happy if he can bring down his game. Their flesh, though seldom fat, is considered as a great delicacy, and the hunter is well rewarded for his trouble.

**FALSE QUARTER**—is a defect in the hoof of a horse, originally sustained by some injury, producing a destruction of parts; as quittor, canker, wounds, treads, bruises, or such formation of matter, by which a part of the hoof has been unavoidably destroyed, or necessarily taken away. In the regeneration of parts, the incarnation (from the rigid and horny nature of the hoof) is irregular and imperfect, forming a sort of cleft (or artificial union) with the sound part upon the surface, productive of a sensible weakness underneath. This imperfect and defective junction renders such quarter, as it is called, inadequate to the weight it is destined to bear; in which case much judgment is required, and may be exerted, in the palliation, as perfect cure is not to be expected. Care must be taken in forming the shoe to relieve the tender part from

pressure, by hollowing it at that particular spot, and letting the bearing be fixed entirely upon the sound parts. By constant attention in reducing the prominent edges of the irregular projection with the fine side of the rasp, and a few occasional impregnations with fine spermaceti oil, the hoof may be sometimes restored to its original formation.

**FAR**, in the manege, a term used to denote any part of the horse's right side: thus the far foot, far shoulder, &c. is the right foot, right shoulder, &c.

**FARCY** is a chronical disorder, which takes place in consequence of a relaxation and obstruction in the absorbent vessels, which are very numerous and large in the posterior extremities of the horse, consequently produces swellings in the legs, belly, and other parts of the body. When these swellings are large, they are known

by the name of water-farcy; but as the disease takes root, the lymphatic veins also swell, and will soon appear like knotted cords; these knots are produced by the valves with which these kind of vessels are particularly supplied; the knotting obstructions taking place at each valve, occasions them to burst, and produce ulcers of a bad nature, and difficult to cure, which, in a very short time, spread all over the body; this state of the disease is termed the corded and button farcy.

If the disorder has been neglected or ill-treated, the swellings of the legs and other places increase; the horse falls off his food, he grows lean, a consumptive fever comes on, and a running at the nose takes place, which, in its further progress, often announces, that the farcy has degenerated into the glanders. The causes that produce this disorder, may be general debility, foul feeding, a want of proper exercise, a schirrous state of the mesenteric glands, or from an affection of the secretory organs, or from an impurity of the serum; and, whatever diminishes the vital heat. The strangles greatly exalt the malignity of this disorder.

At the beginning of the disease a considerable enlargement and pain are perceived in the affected absorbents. Glandular tumours begin to spring up, at first extremely sensible, but soon becoming schirrous; and if these symptoms are permitted to increase, those little tumours soon discharge a foul and corroding sanies, which gives the disorder a very ugly appearance, by spreading themselves with a considerable rapidity all over the body. When the disorder attacks the head first, it may be expected it will proceed with greater violence, and will terminate with more pernicious consequences, than at any other part of the body, as this last symptom frequently announces it will finish in the glanders. Another case equally fatal, is, when the farcy retreats from the outward parts of the body, and falls upon some internal viscera, such as the lungs, intestines, &c.

The cure. When the animal is fleshy, or in high condition, bleeding, and a little mild purging physic, cooling diet, and a great deal of gentle exercise, will be required.

But should the animal be low in condition, his hide bound, his coat staring, it cannot but be obvious, that medicines, having a tendency to reduce the system, must be avoided, which symptoms announce, that the constitution of the ani-

mal has become vitiated by the absorption of the poison produced by farcy; the buds will be numerous, the absorbent vessels, and sometimes the veins accompanying them, will be hard and distended; painful swellings will probably attack the extremities, and the whole frame will soon wear a haggard and distressing appearance.

At such a period, and indeed in every degree of farcy, we may give the following balls, gradually increasing the proportion of the active material, until it has arrived at three or four times its original quantity. Particular care must be taken the horse is not exposed to cold air, his cloathing warm, and a moderate gentle exercise twice a day.

Should the animal feel sore about the mouth or throat, purge or stale too much, from the use of those balls, in this case, the use of medicines should be discontinued until these effects disappear, and the horse recovers his appetite, viz. take of muriate of quick-silver, (corrosive sublimate), an ounce; antimony, four ounces; flowers of sulphur, eight ounces; anisated balsam of sulphur, a sufficient quantity to form sixteen balls. One of these, or of the following, may be given every day.

Take arsenic an ounce, antimony, four ounces, flowers of sulphur, eight ounces, anisated balsam of sulphur, a sufficient quantity to form sixteen balls. The use of these medicines must be continued some time after the disease is removed. If any of these balls cause irritation upon the intestines and kidneys, their use must be discontinued; or, it will be adviseable to add half a drachm of opium to each ball.

The diet must be scalded oats and bran, mixed together, with a handful of split beans, at each feed: the cloathing must be warm, his drink made warm also, and white with bran or meal.

The local treatment of farcy must be attempted by frequent application of blisters, as well as the application of actual cautery, which must be repeated as often as necessity requires, being certainly the best local applications, particularly when there are ulcers. Their effect is to diminish the inflammation of the absorbents, by creating an irritation of the skin; while, by stimulating the external absorbents, the action of the internal are also increased. Moreover, the parts that have been blistered, and those cauterized with the hot iron, must be well fomented with a solution of blue vitriol; the parts being previously washed with warm water.

**FARRIER**, sometimes written **FERRIER**. A person or smith who forges horses' shoes and fixes them on. As the notorious errors committed by ignorant persons in this occupation were the cause of many diseases in the foot, it naturally followed that the same practitioners were resorted to for the cure of the latter. Hence every morbid affection in the horse came at last to be treated by farriers, whose miserable blunders, however, have at length awakened the community to a sense of the evils which that most useful animal has been exposed to for so long a period; and the term *farrier* will henceforth be exclusively applied to the mechanic who fashions and fixes the horse's shoe, under the direction of the veterinary surgeon. In the farrier, too, some degree of sagacity and discrimination is necessary in the application of the new principles which should direct him in the exercise of his art.

**FEATHER**. The central division, and different directions, of the surrounding hair in a horse's forehead is so called: they are also frequently seen upon the neck on one or both sides the mane, and sometimes upon the hind quarters.

**FEATHER WEIGHT**. The lightest weight that can be put upon the back of a horse, in whatever match he may be engaged, and totally depends upon the will of the owner; who is not under the necessity of bringing his rider to the scale either before or after the race, in an engagement where "feather weight" is particularly expressed.

**FEBRUARY**. Shooting continues during this month as far as relates to the snipe and the wood-cock, and perhaps wild fowl, though such of these birds as breed in this country ought to be no longer pursued.

Coursing continues, and hares generally run well, unless the females in a state of gestation,—a circumstance not uncommon in the month of February.

Hares still pursued by hounds; and when the male happens to be found some distance from home, he will afford an excellent run, and that too in a direct line, which renders the pursuit something like that of a fox.

Foxes frequently afford capital runs during this month.

**FEEDER**. A person appointed to prepare, boil, and mix the provision for hounds.

**FEEL**, in the manege. To feel a horse in the hand is to observe that the

will of the horse is in the rider's hand, that he takes the bridle, and has a good appui in obeying the bit. To feel a horse upon the haunches is to observe that he plies or bends them, which is contrary to leaning or throwing upon the shoulders.

**FEET**. The feet of horses being the very basis of support upon which the safety and expedition of the frame entirely depend, they are entitled to every possible degree of care and attention; more particularly in the winter season, when, from neglect, so many ills and inconveniences are known to arise. As the injuries, accidents, and diseases, to which the feet are constantly liable, will be found individually enlarged upon under distinct and separate heads, it becomes only necessary here to lay down general rules for the management of the feet.

The feet of different horses vary exceedingly in what may be termed the texture or property of the hoof; and this is, in general, regulated by the colour of the legs and feet. There are few horses with white heels, but what have white hoofs also, and these are supposed to be more liable to defects and weakness, than those of an opposite description. To preserve feet perfectly sound, cleanliness is the leading principle. After exercise or use, so soon as the body is drest, the dirt or gravel should be carefully taken from under the shoes with a picker, the feet well washed, and legs and heels rubbed dry. Horses left with wet legs and heels, after a severe run, or long journey, particularly in sharp easterly winds, or during frost and snow, will be very liable to cracks or scratches. So severe a rigidity is occasioned in the very texture of the integument, that it becomes partially ruptured or broken in various places, upon being brought into expeditious action; which, with the friction and irritation then occasioned by the sharp particles of gravel in dirty roads, soon produce lacerations of the most painful description.

The state of the shoes should be constantly attended to. Permitted to continue too long upon the feet, the growth of the hoof brings the shoe forward, rendering it too short at the heel, when it begins to indent, and sinking upon the foot, soon presses upon the outer sole, constituting pain or disquietude in some horses, and laying the foundation of corns in others. Horses, in moderate work, require new shoes once a month, upon an average, never varying more than two or three

days from that time : indeed, it is not right they should go longer. The penurious plan of removing shoes half worn is truly ridiculous ; they never render service adequate to the expense, and the practice only tends to a more frequent destruction of the hoof. Thrushes should be counteracted upon their first appearance, without being permitted to acquire a corroding virulence. Swelled legs are hardly ever seen in stables where a proper course of discipline, and regular routine of business, is observed ; they proceed from a viscid, sizey state of the blood, a languor in the circulation, a want of exercise out of the stable, or a sufficiency of friction, leg-rubbing, care, and attention within.

FEN BIRDS. The progressions of nature from one class of beings to another, are always by slow and almost imperceptible degrees. She has peopled the woods and the fields with a variety of the most beautiful birds ; and, to leave no part of her extensive territories untenanted, she has stocked the waters with its feathered inhabitants also : she has taken the same care in providing for the wants of her animals in this element, as she has done with respect to those of the other ; she has used as much precaution to render water-fowl fit for swimming, as she did in forming land-fowl for flight ; she has defended their feathers with a natural oil, and united their toes by a webbed membrane ; by which contrivances they have at once security and motion. But between the classes of land-birds that shun the water, and water-fowl that are made for swimming and living on it, she has formed a very numerous tribe of birds, that seem to partake of a middle nature ; that, with divided toes, seemingly fitted to live on land, are at the same time furnished with appetites that chiefly attach them to the waters. These can properly be called neither land birds nor water-fowl, as they chiefly derive their sustenance from watery places, and yet are unqualified to seek it in those depths where it is often found in greatest plenty.

This class of birds, of the crane kind, are to be distinguished from others rather by their appetites than their conformation. Yet even in this respect they seem to be sufficiently discriminated by nature : as they are to live among the waters, yet are incapable of swimming in them, most of them have long legs, fitted for wading in shallow waters, or long bills proper for groping in them.

Every bird of this kind, habituated to marshy places, may be known, if not by the length of its legs, at least by the scaly surface of them. Those who have observed the legs of a snipe or a woodcock, will easily perceive my meaning ; and how different the surface of the skin that covers them is from that of the pigeon or the partridge. Most birds of this kind also, are bare of feathers half way up their thighs ; at least, in all of them, above the knee.—Their long habits of wading in the waters, and having their legs continually in moisture, prevents the growth of feathers on those parts ; so that there is a surprising difference between the leg of a crane, naked of feathers almost up to the body, and the falcon, booted almost to the very toes.

The bill also is very distinguishable in most of this class. It is, in general, longer than that of other birds, and in some finely fluted on every side ; while at the point it is possessed of extreme sensibility, and furnished with nerves, for the better feeling their food at the bottom of marshes, where it cannot be seen. Some birds of this class are thus fitted with every convenience : they have long legs, for wading ; long necks, for stooping ; long bills, for searching ; and nervous points, for feeling. Others are not so amply provided for ; as some have long bills, but legs of no great length ; and others have long necks, but very short legs. It is a rule which universally holds, that where the bird's legs are long, the neck is also long in proportion. It would indeed be an incurable defect in the bird's conformation, to be lifted upon stilts above its food, without being furnished with an instrument to reach it.

If we consider the natural power of this class, in a comparative view, they will seem rather inferior to those of every other tribe. Their nests are more simple than those of the sparrow ; and their methods of obtaining food less ingenious than those of the falcon ; the pie exceeds them in cunning ; and though they have all the voraciousness of the poultry tribe, they want their fecundity. None of this kind, therefore, have been taken into man's society, or under his protection ; they are neither caged like the nightingale, nor kept tame like the turkey, but lead a life of precarious liberty in fens and marshes, at the edges of lakes and along the sea-shore. They all live upon fish or insects, one or two only excepted.

All this class, therefore, that are fed

upon insects, their food being easily digestible, are good to be eaten; while those which live entirely upon fish, abounding in oil, acquire in their flesh the rancidity of their diet, and are, in general, unfit for our tables. To savages, indeed, and sailors on a long voyage, every thing that has life would appear good to be eaten; and we often find them recommending those animals as dainties, which they themselves would spurn at after a course of good living. Nothing is more common in their journals than such accounts as these—"this day we shot a fox—pretty good eating; and this day we shot a heron—pretty good eating: and this day we killed a turtle"—which they rank with the heron and the fox, as "pretty good eating." Their accounts, therefore, of the flesh of these birds, are not to be depended upon; and when they cry up the heron or the stork of other countries as luxurious food, we must always attend to the state of their appetites who give the character.

**FERME**, in the manege, signifies to exercise in the same spot, without stirring or parting.

**FERRET**. A well-known useful little animal. The ferret is of great spirit, strength, and courage, is an inveterate enemy to rabbits, rats, and poultry; in the pursuit of which, it will encounter any difficulty or danger, when once put upon the scent. The body is longer in proportion to its height, than almost any other animal, the weasel and stoat excepted. The colour frequently varies, even in the young of the same dam and the same litter; some being black, with white under the belly; some are of a faint straw-colour, yellow, and others of a light sandy red. The eyes are small, fiery, having the appearance of red-hot iron, and can distinguish objects in the dark. It has a natural and instinctive propensity to burrowing, and wherever the head can enter, the rest of the body can easily follow. Whenever the ferret has secured the prey he is in pursuit of, he extracts the blood with extreme pleasure by suction, but is totally indifferent to the flesh; with the exception of the head of either rabbit or rat, the skull of which he directly destroys with his teeth, the better to enjoy an instantaneous and luxurious feast upon the brains.

The ferret usually produces five or six young at each litter, after a gestation of forty days: the offspring continue blind for thirty days. When used in warrens,

they are hunted with muzzles, or their mouths sewed up, that they may alarm the rabbits and drive them from their burrows to the nets, without having the power to injure them; for if they were enabled to seize them under ground they could never be prevailed upon to leave the earths.

**FETLOCK**. A tuft of hair growing behind the pastern joint of a horse. Hence the joint itself is called the fetlock or pastern joint.

**FEVER**. An augmented velocity of the blood. The almost infinite varieties of causes of this distemper in the human species does so diversify its appearances, and indicate so many ways of cure, that authors who have written upon it are very voluminous and intricate. But the fevers to which brute animals are obnoxious have not the same character by any means, all their diseases being exceedingly simple.

Simple or idiopathic fever, the most usual species that occurs in the horse, is a preternatural acceleration of the blood's motion, and consequent heat. The compound species of this disease, or the associated and symptomatic, result from some morbid matter thrown upon the circulation, which acts with a virulence exactly commensurate with its proper qualities, and pre-existing state of the body. Fever, in brute animals, is associated with a vast variety of diseases, of which catarrh may be mentioned as a familiar instance. It is also a consequence of all violent accidents, as blows, fractures, &c. in which cases it has been named general inflammation. Fever, however, properly such, arises from spasm of the extreme vessels.

The customary symptoms of fever in the horse are, great heat and dryness of the skin, jaws and tongue, a strong breath, the pulse (which, in health, is from thirty-six to forty beats in a minute) quicker than natural or intermitting, dullness and inflammation of the eyes, heaving at the flanks, impeded respiration, the nostrils dilated, the ears and lower extremities hot, restlessness, fickle appetite both to meat and drink, sometimes avidity of drink, frequent casting out of dung balls, and difficulty of staling, high-coloured turbid urine. These signs, at their commencement, Mr. Lawrence observes, may indicate no more than simple fever; but, if neglected, as is too common, either from want of care, or on the plea of necessity, the disease may become dangerous. We accordingly find, that some cases of fever will require the earli-

est assistance of our art to check the symptoms. The removal of fever in these cases must be attempted.

1st. By lessening the force of the circulation by venesection.

2nd. By relaxing the intestines, and expelling any irritating matters, which otherwise would increase the disease.

3rd. By administering such remedies as have a tendency to remove spasm from the extreme vessels, and thus restoring them to the healthy standard of action.

4th. By regulating the horse's treatment in the stable, viz. his diet, exercise, grooming, &c.

Lessening the force of circulation by bleeding is the first object towards the removal of fever. And here, as the state of the blood is to be attended to as a guide in employing phlebotomy, it may be proper shortly to notice the component parts of the blood, in order that the practitioner may be assisted in forming his opinion respecting the quantity necessary to be taken away.

When blood is fresh drawn from a vein, it appears to be homogeneous, and of a red colour; but, when suffered to stand in the vessel, it soon coagulates, and divides into two parts, which are distinguished by the names of crassamentum and serum. The crassamentum is the red cake, and the serum the amber-coloured water in which it floats.

The crassamentum itself, indeed, consists of two different kinds of matter, namely, the red particles and the coagulable lymph; and these, when the animal is in a healthy state, are so intimately blended as to appear, when cold, a red uniform mass.

But, in cases of inflammation and fever, where the action of the heart and arteries is increased, the blood is longer in coagulating; and the red particles being heavier than the coagulable lymph, which should suspend them, separate and fall to the bottom. This causes the yellow or buffy coat which is seen on the surface of coagulated blood in these diseases; and as the mass of crassamentum is greater or less in proportion to the serum, and more or less covered with a thick yellow matter, so are we to estimate the degree of inflammation existing in the system, and the necessity for farther bleeding.

An attack of simple fever, taken in time, will commonly submit, in two or three days, to a course of medicine and treatment nearly similar to that recommended in a slight case of catarrh (see

CATARRH). Mr. Lawrence proposes to bleed at discretion as to quantity, and give the following drink:

Take of Nitre, from one to two ounces;  
Cream of tartar,

Honey, of each a like quantity.

Give in three pints of a warm decoction of bran, or oatmeal-gruel, twice a-day; plying the horse, in the interim, with as much of the latter as he will take, or, if necessary, drenching him with it.

If the inflammatory symptoms are augmented, and attended with violent pulsation, and throbbing in the arteries, so as to indicate the use of the lancet, Mr. Denny says, from three to six pints of blood may be taken away, and the operation repeated in a few hours, if the symptoms or state of blood require it. He observes, that the greatest chance of success depends on early bleeding; for, "in the horse, the progress of disease is much more rapid than in man." After abating the force of the arterial system by bleeding, we are advised to give the following ball:

Take of Calomel,

Antimonial powder, of each  
one drachm;

Nitre, in powder, one ounce;

Treacle enough to form a ball.

This should be washed down with two or three pints of warm oatmeal-gruel, or bran-water.

The large intestines should be emptied by means of clysters administered occasionally. For this purpose,

Take of Oatmeal-gruel, three quarts;

Common salt, two ounces;

Olive oil half a pint.

Mix them.

Eight hours after giving the ball, let the horse have the following powder, dissolved in two pints of thin gruel, sweetened with honey, and repeated every six hours, until the febrile symptoms are abated.

Take of Camphor, in powder, half a  
drachm;

Antimonial powder, one scruple;

Nitre,

Aniseed, of each, in powder,  
one ounce.

Mix them.

The horse should have warm mashies of bran, with a small quantity of oatmeal or corn mixed in them. Hay is to be given in small quantities. The water given for drink should not be quite cold. If the mashies, &c. are refused, he must be sup-

ported by oatmeal-gruel, given three or four times daily, until his appetite returns.

If there be much cough, and without any mucous discharge from the nose, it would be more proper to give the mash in a common nose-bag than put into the manger. The powder may be given in the following, instead of gruel:

Take of Decoction of linseed, two pints;  
Honey, three ounces;  
Tincture of opium, two drachms.  
Mix them.

When the symptoms are abated, it will only be necessary to have the grooming part well attended to, and allow of walking exercise daily. Malt, and small quantities of the best oats, should be mixed with the mash, to recruit the animal's strength; and give the following ball every morning for ten or twelve days:

Take of Coriander seeds,  
Caraway seeds, of each, in powder, half an ounce;  
Peruvian bark, half an ounce;  
Ginger, in powder, two drachms;  
Honey, enough to form the ball."

Whenever fever assumes an alarming appearance, the advice of a skilful Veterinarian should be procured.

FIDGET won as many capital stakes as most horses of his time. He was bred by Mr. Vernon; was got by Florizel; dam by Matchem, out of an own sister to Sweetbrier. In the possession of the Duke of

Bedford, he became a stallion at Wooburn, and was sire of Augusta, Cub, Victor, Frisky, Hamadryad, Nestler, Fantail, Zemise, Granadillo, Lady Sarah, St Vitus; all winners; as well as a great number of colts and fillies, who won large stakes at three and four years old, but ran without a name.

FIGGING. This is done by introducing a piece of ginger, previously bitten, within the sphincter of the anus, where it so irritates the animal, that he seems, by the cocking of his tail, the instantaneous erection of his ears, and the deceptive spirit he displays in action, to be a horse of very superior appearance and value.

FIRING, the application of the firing-iron, red hot, to some preternatural swelling, &c. of the horse, in order to discuss it. This is oftentimes done by clapping the firing iron to the skin without piercing it.

The firing instrument or knife ought to be somewhat rounded on the edge, and gradually thicker to the back, sufficient to keep the heat of the fire for some time. It should be rubbed clean, that no dirt or ashes may stick to it; and not used until the flaming redness is in part gone off.

Firing is frequently adopted in strains of the back sinews, where the subject is said to have broken down; likewise for bone and blood spavins, curbs, splents, and partially to prevent a renewal of sand-cracks, as well as for ring-bones, and lameness in the round-bone.

FISHES. Were we acquainted with no other animals than those which inhabit the land, and breathe the air of our atmosphere, it would appear absurd to be told that any race of beings could exist only in the waters; we should naturally conclude from the effect produced on our own bodies, when plunged into that element, that the powers of life could not there be sustained. But we find from experience that the very depths of the ocean are crowded with inhabitants, that in their construction, modes of life, and general design, are as truly wonderful as those of the land. Their history, however, must always remain very imperfect, since the element in which they live is beyond human access, and of such vast dimensions as to throw by far the greater part of them altogether out of the reach of man.

That they are in every respect, both of exterior and interior conformation, well adapted to their element and modes of life, we are not permitted to doubt. Their shape is not unlike that of the lower part of a vessel. The body is in general slender, flattened on the sides, and always somewhat pointed at the head. This enables them with great ease to cut through the resisting medium which they inhabit. Some of them are endowed with such extraordinary powers

# IMPLEMENTS FOR FISHING.

## F I S H E S

of progressive motion, that they are able not only to overtake the fastest sailing vessels, but, during their swiftest course, to play round them without any apparently extraordinary efforts.

Their bodies are in general covered with a kind of horny scales, to keep them from being injured by the pressure of the water. Several are enveloped with a fat or oily substance, to preserve them from putrefaction, and to guard them from extreme cold.

They breathe by means of those comb-like organs placed on each side of the neck, called gills. In doing this they fill their mouth with water, then drive it backwards with so much force as to lift open the great flap, and force it out behind. And in the passage of this, among the feather-like processes of the gills, all, or at least the greater part, of the air contained in it, is left behind, and carried into the body to perform its part in the animal economy. In proof of this fact, it has been ascertained that, if the air is by any means extracted from the water into which fish are put, they immediately come to the surface and gasp for air. Distilled water is to fish what the vacuum formed by an air-pump is to most other animals. This is the reason why in winter, when a fish-pond is entirely frozen over, it is necessary to break holes in the ice, not that the fish may come to feed, but that they may come to breathe. Without this precaution, if the pond is small and they are numerous, they will die from the corruption of the water. If a string be tied round a fish in such a manner that the free play of his gills is obstructed, the animal will immediately become convulsed, and will not survive more than a few minutes.

Fishes are nearly of the same specific gravity with water, and swim by means of their fins and tail. The muscular force of the latter is very great. Their direct motion is obtained by moving the tail from one side to the other, with a vibrating motion. When about to move itself, the fish turns the end obliquely to the water, and moves it through in that position. The water re-acts obliquely against the tail, and moves him partly forward, and partly laterally. The lateral motion is corrected by the next stroke the contrary way, while the progressive motion is continued. Assisted by their tail, they turn sideways : striking strongly with it on that side, and keeping it bent, it acts like the rudder of a ship. The fins of a fish keep it upright, especially the belly fins, which act like two feet : without these he would swim with his belly upwards, as the centre of gravity lies near the back. By contracting or expanding the fins, these also assist him in ascending and descending : by inclining his tail obliquely, and turning it a little from an erect position to one side, it helps him to rise and fall.

In addition to the fins and tail, the air-bladder is of material assistance to the fish in swimming, as it is by means of this that they increase or diminish the specific gravity of their bodies. When by their abdominal muscles they press the air contained in it, the bulk of their body is diminished, their weight, compared with that of water, is increased, and they consequently sink. If they want to rise, they relax the pressure of the muscles, the air-bladder again acquires

## F I S H E S

its natural size, the body is rendered more bulky, and they ascend towards the surface. This bladder lies in the abdomen, along the course of the back-bone : in some fish it is single, and in others double : but in the latter case the two parts communicate by a small canal. The air appears to be conveyed into it from the blood, by means of vessels appropriated to the purpose, and it can be discharged thence either into the stomach or the mouth.

Those fish that are without air-bladders have much less facility in elevating themselves in the water. The greater part of them remain at the bottom, unless the form of their body enables them to strike the water downwards with great force. This the rays do with their large pectoral fins, which are sometimes, and not improperly, called wings, since the means which these fishes use in elevating themselves are precisely the same as those employed by birds in flying. When the bladder of a fish is burst it is never afterwards able to rise. From a knowledge of this fact, the fishermen, after taking a quantity of cod-fish, are able to keep them alive for a considerable time in their well boats. They perforate the sound or air-bladder with a needle, disengage the enclosed air, and then throw them into the well, where they immediately sink to the bottom. Without this operation, they would not be able to keep them under water.

The teeth of fishes are usually situated in their jaws : sometimes, however, they are found on the tongue or palate, and even in the throat. They are generally sharp-pointed and immoveable ; but in the carp they are obtuse, and in the pike so moveable as to appear fixed only to the skin.—The tongue is in general motionless, obtuse, and fleshy ; and in the herring, and some other species, this is set with teeth, to enable them the better to retain their food.-- Being furnished with nostrils and olfactory nerves, there can be little doubt of fish possessing the sense of smelling.

The bones are formed of a kind of intermediate substance, between true bones and cartilages. The back-bone extends through the whole length of the body, and consists of vertebræ, strong and thick towards the head, but weaker and more slender as they approach the tail. Each species has a determinate number of vertebræ, which increase in size with the body. The ribs are attached to the processes of the vertebræ, and enclose the breast and abdomen. Several fish, as the rays, have no ribs ; and others, as the eel and sturgeon, have very short ones. Between the pointed processes of the vertebræ lie the bones that support the anal and dorsal fins, which are connected with the processes by a ligament. At the breast lie the sternum, the clavicles, and the scapulæ, on which the pectoral fins are placed ; the bones that support the ventral fins are called the *os sa pelvis*. Besides these, there are often other small bones between the muscles to assist their motion.

The sight of fishes is perhaps the most perfect of all their senses.

The eye, in the greater part of them, is covered with the same transparent skin that covers the rest of the head. The use of this is, probably, to defend it in the water, since there are no eyelids.—The globe is somewhat depressed in front, and is furnished behind

## F I S H E S

with a muscle, which serves to lengthen or flatten it, according to the animal's necessities. The crystalline humour, which in quadrupeds is flattened, is in fishes nearly globular. The eyes are usually thought to be immoveable, but gold fish have been observed apparently to turn their eyes in their sockets, as their occasions require. These fish take little notice of a lighted candle, though applied close to their heads; but on any sudden stroke against the stand, on which the bowl containing them is placed, they flounce about, and seem much frightened. This is more particularly the case when they have been motionless, and are perhaps asleep; from their eyes being always open, it is not, however, easy to discover when they are sleeping and when not.

In fishes, the organ of hearing is placed on the sides of the skull, or the cavity that contains the brain; but, differing in this respect from that in quadrupeds and birds, it is entirely distinct and detached from the skull. In some fishes, as those of the ray kind, the organ of hearing is wholly surrounded by the parts containing the cavity of the skull: in others, as in the salmon and cod, it is in part within the skull. In structure it is by no means so complicated as in the quadrupeds and other animals that live in the air. Some genera, as the rays, have the external orifice very small, and placed on the upper surface of the head; but in others there is no external opening whatever.

The food of these animals is almost universal in their own element. Insects, worms, or the spawn of other fish, sustain the smaller tribes; which, in their turn, are pursued by larger foes. Some feed on mud and aquatic plants, but by far the greater part subsist on animal food alone; and they are so ravenous as often not to spare those of their own kind. Those that have the most capacious mouths pursue nearly every thing that falls in their way, and frequently meet in fierce opposition. The fish with the widest mouth is usually victorious, and he has no sooner conquered than he devours his antagonist. Innumerable shoals of some species pursue those of another through vast tracts of the ocean; from the vicinity of the pole sometimes even to the equator. In these conflicts, and in this scene of universal rapine, many species must have become extinct, had not nature, accurately proportioned their means of escape, their production, and their numbers, to the extent and variety of the dangers to which they are exposed. The smaller species are consequently not only more numerous and prolific than the larger, but their instinct impels them to seek food and protection near the shore, where, from the shallowness of the water, many of their foes are unable to pursue them.

Fishes are in general oviparous: some few, however, as the eel, and one of the species of blenny, produce their young alive. The males have the *milt*, and the females the *roe*, but some individuals of the cod and sturgeon tribes are said to contain both. The spawn of the greater number is deposited in the sand and gravel: many of the fish, however, which reside in the ocean, attach their ova to sea weeds. The fecundity of these tribes far surpasses that of any other

race of animals. In the spawn of a single cod upwards of nine millions of eggs have been ascertained, and near a million and a half have been taken from the belly of a flounder. Many other fish are endowed with a fertility but little inferior. Such an astonishing progeny, were it to arrive at maturity, would soon overstock the waters. But the numbers are so lessened, that perhaps not one in a thousand survives the host of foes by which they are beset.

The longevity of fish is far superior to that of other creatures; and there is reason to suppose that they are, in a great measure, exempted from diseases. Instead of suffering from the rigidity of age, which is the cause of decay in land animals, their bodies still continue increasing with fresh supplies; and, as the body grows, the conduits of life furnish their stores in greater abundance. How long they continue to live has not yet been ascertained. The age of man seems not equal to the life of the most minute species. In the royal ponds at Marli, in France, there are some fishes that have been preserved tame since the time, it is said, of Francis I. and which have been individually known to the persons who have succeeded to the charge of them ever since that period. The Rev. Mr. White, of Selborne, observed the manner in which fishes die. As soon as a fish sickens, the head sinks lower and lower, and the animal stands, as it were, upon it; till, becoming weaker, and losing all poise, the tail turns over, and at last it swims on the surface of the water with its belly upwards. The reason why fishes, when dead, float in that manner is obvious, because, when the body is no longer balanced by the fins of the belly, the broad muscular back preponderates by its own gravity, and turns the belly uppermost, as lighter, from its being a cavity.

Fish, like the land animals, are either solitary or gregarious.—Some, as trout, salmon, &c. migrate to deposit their spawn. Of the sea-fish, the cod, the herring, and many others, assemble in immense shoals, and migrate in these shoals through vast tracts of the ocean.

In the Gmelinian edition of the *Systema Naturæ*, the fishes are divided into six orders:

1. *Apodal*; with bony gills, and no ventral fins.
2. *Jugular*; with bony gills, and ventral fins before the pectoral ones.
3. *Thoracic*; with bony gills, and ventral fins placed directly under the thorax.
4. *Abdominal*; with bony gills, and ventral fins placed behind the thorax.
5. *Branchiostegous*; with gills destitute of bony rays.
6. *Chondropterigious*; with cartilaginous gills.

**FISTULA.** This disease may be denominated a sinuous ulcer, differing from the true sinus in being of a much longer duration, in having its internal surface and external aperture indurated, and discharging from the opening a fluid of a sanious nature.

All fleshy parts of animals are liable

to fistula: in treating of the horse, however, we are more particularly to attend to that of the parts called the withers and the poll, as being the most frequently met with; and as a knowledge of the method to be pursued with these will afford us a tolerable conception how to act with the rest.

Fistula is produced by blows, bruises from the saddle, or by whatever may cause inflammation. Suppuration taking place, and the matter finding no proper outlet, it insinuates itself gradually into the cellular membrane, where, occupying the interstices of the muscles, and taking various directions, it forms what are termed fistulæ, or pipes, conveying a constant sanious discharge, as has been observed. Injuries of the bones will also produce fistulæ; and to these causes may also be added, the presence of extraneous bodies.

When we undertake the cure of a fistula, it will be requisite, in the first instance, to ascertain the direction it pursues, and whether it materially interferes with any of the larger blood vessels, so as to render a full incision into the parts a matter of too much hazard to be attempted. Finding ourselves secure from any danger of this description, we believe the most effectual practice is, to lay the fistula, or fistulæ, if more than one, so thoroughly open, that we can have a complete view of their internal surfaces. We are not, under this article, attempting to point out a remedy for a simple sinus, where the matter is in a healthy state, and requires only a sufficient passage; but for a disease, which, the discharge having been long detained, assumes a new power, indurating and corroding the contiguous parts. The means that might be found fully adequate to the removal of the former will avail little in the radical or absolute cure of the latter; a more severe system must of necessity be enforced.

When the cavities of fistulæ have been sufficiently exposed by the aid of the knife, they should be dressed with powerfully caustic compositions, until the unsound parts slough away, and the wound presents a healthy aspect. Cleanliness and the milder applications are now to be substituted, taking care that the wound is not closed before the cavities are uniformly healed.

For farther particulars on the nature and treatment of fistulæ in different parts of horses, we refer the reader to their respective heads, as POLL-EVIL, &c.

**FLANK** of a HORSE is the part lying between the last rib and the hind quarter, reaching from the part of the loins nearest the hip bone, to the bottom of the belly nearest the stifle.

**FLEAM.** A well-known instrument used for bleeding horses. Lancets are preferred by some with thin-skinned and

blood-horses. Different kinds of spring-fleams have been invented also; but no one has been produced of sufficient merit to supersede the old and generally established custom.

**FLESHY-FOOTED.** A horse is said to be fleshy footed, when that part of the bottom of the foot on each side the frog, (called the outer sole) is preternaturally prominent, constituting a convexity above the wall or crust of the hoof. In feet of this description, the outer sole, from repeated bruising and battering in constant work upon hard roads, or from an injudicious and destructive paring away with the drawing knife, is so exceedingly thin as to indent with the slightest impression, and being too weak to resist the membranous expansion within, compulsively submits to the internal propulsion, and is thrown into the projecting form already described. Great care is required in shoeing horses with this defect: the inner part of the web of the shoe should be so completely hollowed as not to admit the least chance of bearing upon the prominent part; if it does, tenderness and disquietude (if not lameness) must inevitably follow.

**FLORIZEL.** A bay horse, foaled in 1768, bred by Sir John Moore, Bart. sold to Christopher Blake, Esq. and afterwards passed into the hands of Richard Vernon, Esq. of Newmarket.

Florizel was got by King Herod, out of the Cygnet Mare, dam of Flimnap, King Pepin, Bourdeaux, Sting, &c. At Newmarket First Spring Meeting, 1772, (Tuesday) Florizel, 7st. 13lb. in a Sweepstakes of 300gs. each, h. ft. D. C. received forfeit from Mr. Foley's Flippanta, 7st. 10lb.; and Lord Ossory's Circe, 8st. 3lb. And on Friday, at 7st. he beat Mr. Ogilvy's Pincher, 6 years old, 8st. 7lb. B. C. 1000gs:—Even betting. In the Second Spring Meeting, (Tuesday) he won a Sweepstakes of 200gs. each, h. ft. 8st. 7lb. B. C. beating Mr. Pratt's Florist:—Lord Grosvenor's Mungo, Sir L. Dundas's Ancaster, Lord Bolingbroke's Forsett, and the Duke of Ancaster's Achates, paid:—3 to 1 on Florizel. On Saturday, he beat Mr. Fox's Valentine, aged, 8st. each, B. C. 500gs:—7 to 4 on Florizel. He also, on the same day, at 7st. received 100gs. compromise from Lord Claremont's La Signora, 5 years old, 7st. 10lb. across the Flat, 500gs. h. ft. Florizel was sold to Mr. Vernon; and in the Craven Meeting, 1773, at 8st. he received 75gs. from Mr. Fox's Zamora, 8st. 5lb. R. M. 300gs, h.

ft. In the First Spring Meeting, Lord Rockingham was to start one of two Sampson colts, against either Florizel or Bluff, by Mr. Gibson's Arabian, 8st. 7lb. each, B. C. 500gs. h. ft.—Lord Rockingham paid 138gs. compromise. In the same meeting, at 8st. 4lb. he beat Mr. Fox's Zamora, 8st. Ditch-in, 300gs.:—6 and 7 to 4 on Florizel. In the Second Spring Meeting, he walked over for the Claremont Cup, value 125gs. and 100gs. each, for horses, &c. B. C.—Lord Grosvenor's Mambrino, 5 years old; and Mr. Fox's Zamora, 5 years old, paid 50gs. each, forfeit:—Lord Farnham's Sempronius, 4 years old, was drawn by consent. In the Houghton Meeting, he won the Grosvenor Plate of 100gs. for three-year olds, 6st. 7lb. four-year olds, 7st. 9lb. five-year olds, 8st. 5lb. and six-year olds, 8st. 9lb. Ditch-in, beating Mr. Foley's Fire-tail, 4 years old; Mr. Ogilvy's Consul, 6 years old; Mr. Fox's Pastor, 3 years old; the Duke of Ancaster's Cynthius, 3 years old; Lord Farnham's Flirt, 3 years old; Mr Strode's Rantipole, 4 years old; and Mr. Burlton's Slouch, 3 years old:—6 to 4 against Florizel, and 7 to 4 against Firetail. In the Craven Meeting, 1774, he was second to Sweetwilliam, for the Craven Stakes, beating 23 others. In the First Spring Meeting (Monday) Florizel, 9st. 7lb. beat Mr. Pigott's Shark, 2 years old, 6st. 12lb. Ditch-in, 300gs.:—7 to 4 on Florizel. And on Saturday, at 10st. he beat Lord Abingdon's Myrtilla, 3 years old, 8st. Ditch-in, 200gs.:—5 to 2 on Florizel. In the Second Spring Meeting, at 9st. 2lb. he won a Sweepstakes of 100gs. each, h. ft. B. C. beating Mr. Strode's Britannicus, aged, 8st. 3lb.; Mr. Foley's Pastor, 5 years old, 6st. 12lb.; and Sir F. Evelyn's Miranda, 6 years old, 7st. 10lb.—Lord Grosvenor's Stoic, 6 years old, 8st. 8lb.; and Sir C. Bunbury's Langham, 5 years old, 7st. 12lb. paid:—6 to 4 against Florizel. In the Second October Meeting, he won a Subscription of 10gs. each, (18 subscribers) for four-year olds, 7st. 11lb. five-year olds, 8st. 8lb. and six-year olds, 9st. D. C. beating Lord Grosvenor's Sweetwilliam, 6 years old; the Duke of Grafton's Lamplighter, 5 years old; Mr. Strode's Ranger, 6 years old; Mr. Foley's Enterprize, 4 years old; and Lord Clermont's Ainderby, 5 years old:—3 to 1 on Sweetwilliam, 4 to one against Florizel, 20 to 1 against Ranger, and the same against Enterprize. In the Houghton Meeting, he won the Subscription-Purse

of 100gs. for three-year olds, 6st. 9lb. four-year olds, 8st. 3lb. five-year olds, 8st. 13lb. and six-year olds, 9st. 4lb. the last three miles of B. C. beating Mr. H. Vernon's Jack of Hilton, 3 years old; Lord Grosvenor's Morwick, 5 years old; Sir C. Bunbury's Wolsey, 4 years old; Mr. Walker's Bedfellow, 3 years old; the Duke of Ancaster's Hephrestion, 3 years old; Lord March's Slim, 3 years old; Lord Bolingbroke's Tom Thumb, 3 years old; Lord Farnham's Pierrot, 3 years old; Lord Milsintoun's Desdemona, 4 years old; Mr. Douglas's Tyrant, 5 years old; and Lord Clermont's Merrylass, 3 years old:—Even betting on Florizel.

Florizel was beat eight times.—He paid four forfeits, viz. at three years old, 100gs. in a stakes won by Ramjam, who was to have allowed him only 6lb. for two years; at five years old, 250gs. in a stakes won by Mambrino, (same age) to whom he was to have allowed 8lb.; at six years old, 100gs. in a stakes won by Firetail, to whom he was to have allowed 12lb. for his year;—and when aged, 100gs. compromise to Transit, which was his last engagement.

Florizel was a stallion at Hunstanton, near Docketing, Norfolk, at 10gs. and 10s. 6d.;—except in 1781, when he was stinted to 40 mares, (besides those of his owner) at 20gs. and 10s. 6d. but the mares were allowed half a peck of corn per day, and two months keep, *gratis*;—and in 1789, he was a private stallion, except for 20 mares at 21gs.—He again covered at 10gs. and 10s. 6d. until the time of his death, which happened in the latter end of the year 1791, being then aged 23.

FLY-FISHING. Fishing with an artificial fly is an interesting method of angling; yet fly fishing is not without its disadvantages, for there are many kinds of fish that will not rise at a fly, whereas, all the different species which the fresh waters produce will take a bait at bottom at some season of the year; and it is also worthy of notice, that the angler who fishes at bottom, has many months and days in the year when fish will so feed, consequently he has frequent opportunities of enjoying his amusement when the fly fisher is entirely deprived of the chance of sport by very cold, or wet weather, the winter season, &c. Fly fishing partakes more of science than bottom fishing, and of course requires time, study, and practice, before the angler can become any thing like an adept at making or casting a

fly. The young angler would gain much more information on the subject by attending a fly fisher while he is casting or making an artificial fly; if he cannot avail himself of such knowledge, he must persevere and strictly follow the directions offered to his notice. There are many excellent fly fishers who never trouble themselves to make a fly, yet kill trout in every trout stream they fish, with flies bought at the London tackle shops, where the angler may get a fly made to any colour, pattern, or shape he may want; indeed, flies are now made so well at those shops, that it is scarcely worth the angler's trouble to make them. I should recommend the young fly fisher, in the first instance, to purchase his artificial flies; but, after some experience in the art, to make his own. In purchasing artificial flies the following will be proper to select: red and black palmers, red and black hackles, grouse, red and black ant-flies, the yellow May fly or green drake, stone fly, small black gnat flies, the red spinner, and the white moth. Having purchased the above assortment of flies, the angler should make himself well acquainted with their several forms, the number of wings, and every other particular, that he may be able to know every difference between the several kinds, thereby guarding against having flies imposed on him of a species different to what he may think proper to order.—The flies above enumerated are all of established credit; their respective merits, the way and materials of which they are made, will be found under their different names. In many places certain flies are preferred; the bean or thistle fly has been considered a secret in some parts of Wales and much valued. There is a fly used very much at Watford, in Herts, called Harding's fly, or the Coachman's; of the merits of such flies experience will teach how to appreciate. Note, make it an invariable rule to try a red or black palmer, first in the morning and last in the evening, when whipping for trout; the other part of the day winged flies.

*Concise Directions how to make an Artificial Fly.*—Take some fine silk, of the proper colour, and wax it well with bees' wax, then hold the bend of the hook between the fore-finger and thumb of the left hand, and with the right give the silk two or three turns round the shank, and fasten it; then take a small feather, of the colour you intend the fly should be, strip off some of the fibres towards the quill, and leave a sufficient quantity for

the wings, holding the point of the feather between your finger and thumb, turn back most of the remaining fibres, and laying the point end of the feather upon the hook, give a few more laps round it with your silk, and fasten; then twirl the feather round the hook till all the fibres are wrapped upon it, which done, fasten and cut off the two ends of the feather; then, with dubbing of the proper colour twisted round the remaining silk, warp from the wings towards the bend of the hook, till the fly is the size required. Before the young artist tries his skill at dressing or making a fly, he should take an artificial one to pieces, and observe well how it is formed.

The knowledge how to make the May flies is first requisite to be understood; for these flies are of so much value to the angler, that every one who wishes to excel in fly-fishing, should learn how to make them as soon as possible.

*The Artificial Green Drake or Yellow May Fly and others.*—Make the body of seal's fur, or yellow mohair, a little cub fox down, or hog's wool, or camel's, and bear's hair mixed; warp with pale yellow and green silk, waxed to imitate the joints of the fly's body under the wings; the wings to be made of a mallard's or wild drake's feather, dyed yellow, (put a handful of horse radish leaves into a pint of water, to which add a piece of alum the size of a small walnut; simmer the whole for some time, and it will then dye feathers, silk, &c. a yellow of any shade and fast colour;) three whisks for the tail from a sable muff, or the whiskers of a black cat, or hairs from a dog's tail. When this green drake is made small, it is then generally denominated the yellow May fly.

*Grey Drake.*—Make the body from a white ostrich's feather; the end of the body next the tail, peacock's herl; warping of ash-colour, with silver twist, and black hackle; wings of a dark grey feather of a mallard,

*Stone Fly.*—To form the body of this fly, take bear's dun, and a little brown and yellow camlet well mixed, but so placed that the fly may be more yellow on the belly, towards the tail underneath, than in any other part; place two or three hairs of a black cat or dog, beard or whiskers, or the fibres of a dark hackle, or the bristles that grow under the chin of horses, on the top of your hook, in the arming, so as to be turned up when you warp on your dubbing, and to stand almost upright,

branching one from the other; rib with yellow silk, make the wings large and long, of the dark grey feather of a mallard.

The formation of these artificial May-flies will be rendered easier, by an intimate acquaintance with the natural ones.

*Natural May Flies, Ephemera, Vulgate May Fly, or Green Drake.*—This May-fly is bred from the cad-worm, and is found in numbers beside most small gravelly rivers, near the banks where bushes grow and over-hang the water, to which places they fly when they change from their chrysalis state: its wings (which are single) stand high on the back, like the butterfly.

The body of this fly is a yellow, ribbed across with green; the tail consists of three small whisks, quite dark, and turned upwards to the back, like the tail of a drake or mallard; from the green stripes on the body, and its turned up tail, this May fly receives the name of green drake; in some places it is also called the cock-up or tilt-up tail, so is the grey drake.

*Grey Drake.*—The grey drake, in shape and size, is like the green drake, but different in colour, being a lighter yellow, and striped with black down its body; the wings are glossy black, and thin like a cob-web.

*Stone Fly: called the Water Cricket or Creeper while in the state or form of a maggot.*—The stone-fly escapes from the husk or case before the wings are sufficiently grown to enable him to fly, and creeps to the crevices of stones, from which circumstance the name is derived: they are found in almost all trout streams, or stony rivers, and are known by the angler for trout as a killing bait. The body of the stone-fly is long and thick, of a brown colour, ribbed with yellow, and has whisks at the tail, and two small horns on his head: when full grown, the wings are double, and of a dusky dark-brown colour. This fly has several legs, and uses them more than his wings, as you may often find them paddling on the top of the water, only moving their legs. The three flies just described, namely, the green-drake, the grey-drake, and the stone-fly, are all known by the name of the May-fly. Although the green drake, the grey drake, and the stone fly, are all termed May-flies, yet the young fly fisher should be apprised, that when the May fly is spoken of among anglers, they generally mean the green drake, or as some call it, the yellow May fly, from the colour of its wings, and it

certainly is the most general killing May fly.

*Plain Palmer or Hackle.*—First provide a short length of gut, about fifteen inches long, and a hook, No. 7, or 8, some red silk well waxed with red wax, a fine red hackle, and some ostrich feathers: hold the hook by the bend, between the fore-finger and thumb of the left hand, with the shank towards the right hand, and with the point and beard of your hook nearly parallel with the tops of your fingers, then take the length of silk about the middle, and lay the one half along the inside of the hook towards your left hand, the other to the right, then take that part of the silk that lies towards your right hand, between the fore-finger and thumb of that hand, and holding that part towards your left tight along the inside of the hook, whip that to the right, three or four times round the shank of the hook, to the right hand; after which, take the gut, and lay one end of it along the inside of the shank of the hook till it comes near to the bend, then hold the hook, silk, and gut tight between the fore-finger and thumb of your left hand, and afterwards give that part of the silk to your right hand three or four whips more over the hook and gut, till it comes nearly to the end of the shank; make a loop and fasten it tight; then whip it neatly again over silk, gut, and hook, till it comes near the bend of it, after which, make another loop, and fasten it again; then if the gut reaches farther than the bend, cut it off, and your hook will be whipped on, and the parts of the silk will hang from the bend of it: then wax the longest ends of the silk again, and take three or four strands of an ostrich's feather, and holding them and the hook as in the first position, the feathers to the left hand, and the roots of them in the bend of the hook, with the silk you waxed last, whip them three or four times round, make a loop, and fasten them tight; then turning the strands to the right hand, and twisting them and the silk together, with the fore-finger and thumb of the right hand wind them round the shank of the hook till you come to the place where you fastened, then make a loop and fasten them again: if the strands should not be long enough to wind as far as it is necessary round the shank, when the silk gets bare, you must twist others on it; after which, take a pair of small-pointed sharp scissors, and cut the palmer's body to an oval form. Both ends of the silk being separated at the bend and shank end of the hook, wax

them both again; then take the hackle, hold the small end between the fore-finger and thumb of your left hand, and stroke the fibres of it with your right contrarywise to which they are formed; keep your hold as in the first position, and place the point of the hackle in its bend with that side which grows nearest the cock upward, then whip it tight to the hook—in fastening it, avoid tying in the fibres as much as possible: the hackle being fastened, take it by the large end, and keeping the side nearest the cock to the left hand, begin with your right hand to wind it up the shank upon the dubbing, stopping every second turn, and holding what you have wound tight with your left fingers, whilst with a needle you pick what fibres may have been taken in: proceed in this manner until you come to the place where you first fastened, and where an end of the silk is, then clip those fibres off the hackle which you hold between your fore-finger and thumb, close to the stem, and hold the stem close to the hook; afterwards take the silk in your right hand, and whip the stem quite fast to it, then make a loop and fasten it tight. Take a sharp knife, and if that part of the stem next the shank of the hook, is as long as the part of the hook which is bare, pare it fine; wax your silk, and bind neatly over the bare part of the hook, then fasten the silk tight, and spread some shoe-maker's wax lightly on the last binding; then clip off the end of the remaining silk at the shank and bend of the hook, also any fibres that may stand amiss.

*Directions for making a Golden or Silver Palmer.*—The dubbing the same as the palmer, ribbed with gold or silver twist, with a red hackle over all. When you whip the end of the hackle to the bend of the hook, you must do the same to the gold or silver twist, first winding either of them on the dubbing, observing that they lie flat on it, and then fasten off, then proceed as before directed with the hackle.

Small light coloured flies are most proper for clear shallow water, during a bright sky, and the larger sort for dark weather, and thicker or deeper waters.

*Materials for making Artificial Flies.*—Get seals' and moles', squirrels' and water rats' furs; also mohairs, black, blue, purple, white, and violet; camlets, of every hue and colour; and fur from the neck and ears of hares, hogs' down, and bears' hair; hackle feathers; get them of the following colours, but not too large: red, dun, yellowish, white, and perfect

black. Feathers to form wings, &c. of flies, are got from the mallard and partridge, especially those red ones in the tail; feathers from a cock pheasant's breast, and tail, the wings from the blackbird, the brown hen, the starling, the jay, the land-rail, the thrush, the field-fare, the swallow, and the water coot; the feathers from the crown of a plover, green and copper-coloured; peacock's and black ostrich's herl, and feathers from the heron's neck and wings. You must also be provided with marking silk, fine, strong, and of all colours; floss silk, gold and silver flattened wire or twist, a sharp knife, hooks of all sizes, shoe-maker's wax, a large needle to raise your dubbing when flattened, and a pair of sharp pointed scissors. A little portable vice is necessary to fix on the table, to which you may occasionally fasten your hook while dressing a fly.

*A List of Flies for every Month during the Season, commencing with April.*—Artificial flies are called dub flies when the body is principally made of wool or mohair, when chiefly made of feathers they are called hackle flies. If the body is like a palmer to which is added wings, then it is properly called a palmer fly.

There are upwards of a hundred different kinds of flies made for fly fishing, suitable for every month during the season, and which may be purchased at a small expense at the tackle shops, should the angler decline making them himself.

*April.*—The cow-dung fly may be used from the first of this month, and is a killing fly to the end. The brown or dun drake is a good fly in the middle of the day, particularly if the weather proves gloomy.

*May.*—The stone-fly may be used all this month with much success, but more particularly in the mornings. The yellow May fly will answer, especially in the evenings, during the whole month. The black caterpillar fly is a good fly, and so is the black-thorn fly this month, in small rivers and trout streams; it kills best in those days that succeed very hot mornings. The fly called the camlet, may be used all day till the middle of June, for small fish.

*June.*—The lady-fly is now a good one, particularly when the water begins to brighten after a flood. The black gnat-fly in an evening, especially if the weather has been warm and showery. The blue gnat is only used when the water is very fine and low. The red spinner is an excellent fly, but most killing when the water is dark, and late in the evening.

*July.*—The orange-fly is an excellent bait, particularly if this month proves close, hot, and gloomy. The large red ant-fly is killing for some hours in the middle of the day.

The badger-fly is good in the early part of this month, and in the coolest days.

*August.*—The small red and black ant flies are good killers for three or four hours in the afternoon, and sometimes till sun-set, if the sky is occasionally obscured. The small fly, called the light-blue fly, is known to most fly-fishers to be a killing bait from morning till afternoon.

*September.*—The willow fly is most to be depended on this month, and for the remainder of the season: any of those noticed for July or August may also be used occasionally. All the flies I have enumerated are for killing trout, but you may also take chub and dace with them, and perchance a salmon. For making these flies, mohair of various colours, is used; also seal's wool, bear's and camel's hair, sheep's wool, badger's hair, hog's down, camlets of all colours, the fur of hares, squirrels and foxes, feathers from the neck of the game cock, called hackles; likewise feathers from the peacock, &c. and pass your hook through them, under their wings.

Natural fly-fishing is generally termed dapping or dapping, and is practised with a stoutish rod, having a light stiff top, running tackle, strong gut or hair line, and No. 7 or 8 hook, for trout or chub. When dapping with a May fly, put two or three on the hook, which should be carried through the thick part of the fly's body under the wings, with their heads standing different ways, and take care that your fingers are always dry when baiting, or you will soon kill or spoil the bait. Bait the same way with the black ant fly in June, in July use the wasp fly, in August the hazel, or button fly, in September the badger fly, in March and April the thorn fly, yellow dun, and stone flies. The stone fly, when in the state of a maggot, is called the water cricket or creeper, and is to be found in most small stoney rivers or trout streams in April, lying under hollow stones. In those waters where this cricket is found, it will prove an excellent bait the latter end of April; put two or three on a No. 9 hook, and use it as a tripping bait in the middle of the stream. This cricket is a good bait to dap with about noon in the said month.

In this mode of fishing, it is absolutely necessary to kneel down or stand behind a tree, bush, high weeds, or something to

hide your person, or the fish will not rise to your fly or bait. You must draw out as much line as will just let your baited hook reach the surface of the water; then with the top of your rod a little raised, keep the bait in motion, and if you see several fish, cautiously guide your bait to the largest, play it a little an inch or two above the water, by gently shaking the rod, then let it drop just before the fish. When a fish takes your bait, after a moment, strike smartly, and if not too large to endanger breaking, lift him out immediately, for by playing them while dapping, you are very likely to scare away the others by exposing yourself to their sight; but if the wind is brisk, and you stand sufficiently high on a bank or bridge, you may let several yards of line out. The angler may play his bait on the top of the water in streams whose water is nearly level with the bank with success, because he may keep far from the water and yet see arise.

The best bait in June, July, and August, for chub, is the humble-bee during the day; late in the evening, a large white moth, bred in willow trees. When you bait with a live bee, it is necessary first to extract its sting.

They will also take the cock-chaffer or May bug, (but before you put this insect on the hook, take away its upper horny wings) grass-hoppers, the fly called father long-legs, all kinds of moths and small butterflies, also large blue flies, bees, and wasps, generally preferring the largest.

*For Dace* the best bait is the common house fly; you may put two on a No. 10 hook. The time, the last three hours before it is dark, you may use two or three hooks at a time, tied on about three inches of hair or fine gut, and fastened on the line about fourteen inches apart.

*For Bleak.*—One common flesh or house fly on a No. 11 or 12 hook. Dace and bleak are also caught by whipping with an artificial fly.

In casting or throwing a fly while yet a novice, observe the following rules: having fixed the winch on the butt of your rod, draw the line through all the rings of the rod to the top, and then again as much more as will reach within a yard of your butt-end from the top, the line will then of course be nearly as long as the rod, which will be quite as much as is necessary for a learner to throw; indeed, when you have attained the art of throwing a fly thirty yards to any given spot, you may use line *ad libitum*. Having fastened your

bottom with the line, hold the hook by the bend in the left hand between your thumb and finger; the rod in the right hand pointing to the left; bring the top of the rod gently round to the right, making a sweep over your right shoulder, casting forward the fly, which you let go the moment you are in the act of throwing; practise this with a moderate wind at your back, either on land or in water till you have gained the art.

The lighter your fly and line descends on the water, the greater the chance of a bite. Never use more than one hook on your line at a time, till you feel fully confident you can throw your line with one, to any given distance or place: when you commence fishing any water, endeavour to keep the wind at your back, as it enables you to stand farther out of the fish's sight, and you have the additional advantage of fishing both sides of the stream, if not very broad. In small streams, where the middle is shallow, you will always find a rippling on the surface in the shallow part: when you cast in your bait, always take care to throw it in on the opposite side, and draw it slowly to the rippling, letting it float down some distance, and if the fish like your fly, they will certainly take it; or if you see a fish rise in any part of the water, immediately throw your bait just above it, draw the fly gently over the spot where the fish rose, and you will generally take the fish.

**FOAL** is the produce of Horse and Mare in a general sense, including both male and female; but when a more particular description is required, it is customary to say either a colt, or a filly foal.

**FOIL.** A term used in hare hunting. When, during the chase, a hare, after a head or double, runs over the ground she has ran before, she is then said to be running the foil. Old hares, who have speed enough to break away, and get considerably a-head, almost invariably throw themselves out to the right or left, double, and quat; particularly if a hedge-row, hedge, fern, furze, or any kind of covert presents itself favourably for the purpose. The hounds continuing to run the scent to the spot where she made her head, over-run the hare, and having no continuance of scent, are of course at fault; during which delay of trying forward, trying back, making a cast to the right, then a cast to the left, the hare slips into her foil; by repeatedly running of which with the same instinctive sagacity, she as repeatedly saves her life; without which,

and many similar innate shifts to avoid their numerous enemies, there would not long be a hare left in the country.

**FOMENTATION** is, perhaps, the most generally useful of all external applications, and cannot be too much encouraged. In all inflammatory tumours and enlargements arising from strains, blows, bruises, and various other injuries, the efficacy of hot and persevering fomentation is well known. Its properties are twofold, inasmuch as it assists nature in whichever is her most predominant effort, either for absorption or suppuration.

Fomentations are prepared by boiling three or four double handfuls of the different kinds of aromatic garden herbs in six quarts or two gallons of water, occasionally stirring them for a quarter of an hour; then let the part affected be patiently fomented with sponges or flannels, alternately dipped in the decoction, as hot as it can be consistently used without injury to the hair. If the tumour, or enlargement, does not threaten suppuration, the absorption may be assisted by a gentle persevering friction in hand-rubbing, previous to the application of such repellent as may be thought applicable to the case: on the contrary, should a formation of matter have evidently taken place, the intention of nature cannot be too expeditiously promoted; an emollient poultice should instantly follow the fomentation, and both be repeated once or twice a-day, according to the magnitude of the emergency.

The herbs chiefly in use for fomentations (and from which any three or four may be selected) are Roman and common wormwood, mallows and marshmallows, lavender leaves and flowers, rosemary leaves, camomile flowers, elder flowers, and bay leaves.

**FOOT.** The foot of a horse extends from the fetlock-joint to the outer sole at the bottom of the hoof: it includes the coronary-bone, the nut-bone, and the inner sole, in which it is deposited; as well as the frog and the wall or hoof surrounding and supporting the whole.

**FOREHAND** of a horse. That part of the animal which is before the rider. See the articles Conformation, &c.

**FOREHEAD** of a horse. This should be somewhat broad: some would have it a little raised; but a flat one is most beautiful. A horse should have in his forehead what is called a feather. It is also to be desired that he should have a star or blaze in his forehead.

**FORE-LEGS.** The fore-legs of a horse are generally considered to begin at the lower extremity of the shoulder-blade: they consist of what are termed the arms, (or fore-thighs,) which extend to each knee; the shank-bone from the knee to the fetlock-joint; the fetlock-bone is continued from thence to the coronary-bone, into which it is inserted; the coronary-bone in part fills the cavity, or box of the hoof, being lodged in the coffin-bone, supported by the nut-bone behind; these last are deposited in the membranous mass denominated the inner sole; the whole being terminated by the bottom of the hoof, the frog, and the outer sole. The fore-legs, to be uniform, (in a front view,) should be wide at the upper part next the breast, strong and broad in the arm, bony below the knee, free from splents, a broad sound hoof, firm sole, and a frog without thrushes.

**FOREST.** A forest is a large tract of land in pasture, many miles in extent and circumference, the property of the crown, mostly well stocked with timber, (from whence the navy is supplied,) as well as with a variety of underwood, furze, fern, &c. for the breeding and preservation of both venison and game. Forests are of great antiquity, and their immunities are protected by laws peculiarly and solely adapted to their preservation; the execution of which are lodged in principal officers, and their subordinates, justices in eyre, chief wardens, verderers, regarders, foresters, woodwards, agistors, rangers, beadles, and keepers.

A forest has its foundation under a commission bearing the great seal of England, and when proclaimed through the county in which the land so appropriated lies, "that it is a forest, and to be governed by the laws of a forest," it then becomes a forest upon record, and the officers before mentioned are appointed. A forest has its "boundaries," its "purlieus," its "properties," its "courts," with a variety of regulations equally uninteresting and unentertaining.

There were sixty-nine forests in England, of which the New Forest, Windsor Forest, Sherwood Forest, Charnwood Forest, Whittlebury Forest, and the Forest of Dean, have always been considered the principal.

The beasts of forest, in all ancient records, were denominated "beasts of venery," and consisted of the hart, hind, hare, boar and wolf: the complete extinction of the two latter has, however,

long since rendered the term unnecessary.

**FOREST COURTS** are the courts occasionally held for executing the forest laws. The principal of which is, the court of the chief justice in eyre; this is a court of record, and is only held once in three years. The court of swainmote consists of the verderers, who, in some degree, are the judges; as they receive presentments, and hear evidence, as well as enquire of offences to convict, but cannot pass judgment, that power being reserved to the court of the chief justice (called "justice seat") alone. The court of swainmote can only be held three times a year. The court of attachment is likewise a meeting of the verderers, and held once in six weeks, being called the "forty days court."

**FOREST LAWS** are the laws framed for the protection of vert and venison within the precincts of a forest. It is the business, and the duty, of all subordinate officers, to apprehend offenders of whatever description, and present them to the forest courts, in order to their being punished according to the magnitude of the offence they may have committed.

**FORKED HEADS.** All deer heads that bear two croches on the top, or that have their croches doubled.

**FORMICA.** A distemper so called, which commonly seizes upon the horn of of a hawk's beak, which it will eat away, and generally supposed to be occasioned by a worm. It may be perceived by the beak becoming rugged, and it will ultimately separate from the head. Old falconers inform us, that to remedy this malady the gall of a bull must be broke into a dish, to which must be added the powder of succotrine aloes; these must be well mingled together, and the diseased part anointed therewith twice a day (care being taken not to touch the eyes or nares) till the hawk be perfectly cured.

A disease called the *formica* sometimes appears in the ears of dogs, particularly in the ears of spaniels and pointers. In this disease the ears become scabbed either from being torn with thorns or something of this sort, and the irritation thence arising, frequently induces the animal to scratch the affected part till the sore spreads, and a disgusting mangy appearance presents itself. For the cure of this disorder, sportsmen of the old school prescribe the following:—Infuse four ounces of gum dragon in the strongest vinegar that can be procured, for the space of

eight days, and afterwards bruise it on a marble stone, as painters do their colours; then add two ounces of roach alum and galls; mix all well together, and apply it to the affected part. Now, this may be all very well in its way, and might appear highly scientific at the time it was originally prescribed; but as the indispensable period of its preparation was *eight days*, the ears of a dog thus affected would frequently present a dreadful appearance owing to the ravages of the disorder. Therefore, putting aside this antiquated system altogether, the writer can very confidently recommend a little mercurial ointment for the purpose, the application of which he knows from experiment many times repeated, to be a very effectual and a very speedy cure. If the affected parts are rubbed with mercurial ointment as soon as the disease is observed, one application will often be sufficient: let it be repeated, however, according to the virulence of the disease.

FORM is a spot in which the hare takes her seat at the dawn of day. When found sitting she is said to be in her *form*. Hares vary their sitting according to the season, the sun, and the wind. Soon after harvest, they are found in wheat, barley, and oat stubbles, as well as in rushy, grassy moors; after these become bare, they retire to coverts, banks, hedges and hedge-rows. After Christmas, and in the spring months, dry fallows, particularly those lying towards the sun with an ascent; though the buck hare, as the season advances, will frequently sit in splashes and moist situations.

FOUL FEEDERS. Appetite, if good, in either man or beast, ought to be, and in most cases is, a clear criterion and proof of health. However, instances are not wanting, where a rule so seemingly just is sometimes subject to exceptions. The quantity of good and healthy food taken into the frame, is by no means an infallible proof of strength, or of what work the subject is, or ought to be, equal to: some horses are the greatest slugs in nature, though always feeding; while others, who undergo thrice their labour, do not consume even a moderate share of what is placed before them.

When the appetite of a horse is seemingly never satisfied; when he displays an immoderate and impatient desire for food at all times; when, in failure of repeated supplies of hay and corn, he is constantly consuming his litter, such a horse is generally, and with strict justice, denominat-

ed a coarse and foul feeder; the result of which frequently is, that he soon becomes as foul in his blood, his coat, and condition, as he has previously proved himself in his inclination. The ready road to relief in a case of this kind, is to unload the frame of its accumulated rubbish by a course of physic; the rack rein and the muzzle are then such easy alternatives, that those who do not choose, or are too indolent, to adopt them must sit down easy under the defect.

Some there are who attribute the voracious dispositions, and strong digestive powers, of such horses to their being affected with worms.

Horses of a contrary description, who labour occasionally under a loss of appetite, is no such matter of ambiguity as what has been just described; but may with certainty be ascribed to its proper cause, by minutely attending to such signs, and predominant symptoms, as present themselves to the eye, and to the touch, of the diligent enquirer. A loss of appetite in horses whose constitutions are generally good, and who have not been remarked for refusing their corn, or being off their feed, sufficiently indicates some tendency to either slight and temporary indisposition, or impending disease; as cold, cough, febrile heat from the fatigue of a long journey on the road, or exertion in the field; intestinal disquietude, from flatulent affection, or pain in the kidneys; as well as a stricture upon the neck of the bladder, proceeding from a preternatural retention of urine, in having travelled too far "without drawing bit." This defect, proceeding from whatever cause, cannot be too soon properly attended to: early and attentive investigation should be made as the first and most necessary step to the acquisition of relief. Admitting it to have originated in any of those causes already described, there is very little doubt to be entertained, but a moderate bleeding, a cordial ball, a mash of ground malt and bran, equal parts, with warm soft water, and a little nursing, if expeditiously proceeded upon, will soon set all to rights again.

Not so with those whose defect is constitutional, proceeding from an inexplicable degree of irritability, so generally and palpably evident in both attitude and action; in the stable, or out, they never appear perfectly at ease; the eye, the ear, seeming alarmed with every sound, as if in perpetual search of new causes to keep up the unceasing spirit of discontent and

eternal disquietude. Upon the road in company, or in the field with hounds, they invariably and impatiently court competition, making the most violent exertions to prove their great, passionate, and ill-tempered desire for superiority, so that horses of this description, after a journey of some length, or chase of severe duration, are not only off their appetites for two or three days, but hardly fit to be seen again for a week. They are mostly light, and what is termed thin in the carcase; carry no flesh, with or without work; and for that reason, do no credit in appearance to their master. Yet, strange as it may appear to those unacquainted with the fact, horses or mares of this restless, unsettled disposition, are almost so invariably good and persevering in nature, that they will continue to exert themselves, till, becoming totally exhausted, they must sink under fatigue, rather than permit themselves to be restrained; a palpable contrast in spirit to those voracious, gummy-legged gluttons, who, after an insatiate series of gormandizing and rest, absolutely tire (or "knock up") in the second stage, or first twenty miles, of a journey.

This defect, (or more properly deficiency in appetite and disinclination of food,) whether proceeding from the fiery volatility of temper impatient of restraint, or a peculiar laxity of the parts necessary to strong digestion, is so clearly inherent, so truly constitutional, that a well-founded expectation of permanent relief, or total eradication, is not to be formed upon any change that can be made in food, or improvement in attention. Such horses, however, if their paces are good, and they are desirable in other respects, should not be too hastily disposed of; instances having been very frequent, where horses of such irritable habit, and fretful disposition, when young, have, when accustomed to the same stable, gentle usage, and to one rider only, become as settled feeders, good goers, round carcased, and firm fleshed horses, as any in the kingdom. Some inducement to feed after the fatigues (or frettings) just recited, may be attempted by the means before described; few occasions will occur where the malt mashes will be refused; the novel fragrantcy attracts attention, and, when once taken, its invigorating property soon appears. In cases where the stomach continues weak, the carcase thin, and appetite not restored, an occasional use of the pectoral cordial balls, once or even twice a day, is the proper substitute for aliment, and will

seldom or ever fail to produce the desired effect.

**FOUNDER.** A disease to which horses are subject, after being ridden violently, and afterwards exposed to sudden cold, or washed with cold water. Two kinds of founder have been described; namely, chest-founder, and founder in the feet. There is, however, no good reason for this distinction, as will appear from the following account, given by Mr. Clark, of the symptoms that take place in the different stages of this disorder, together with the circumstances that have appeared on dissecting those horses that have died of it.

The founder, he says, always proceeds from cold too suddenly applied to the body, and whether it be from a current of cold air, or from plunging the body into cold water, when over-heated, the effects are the same. The symptoms at first are these: when the horse begins to cool, he appears very stiff and feeble in his fore-quarters, and, when forced to move forwards, he collects his body, as it were, into a heap, and brings his hind feet as far forward under his body as he possibly can, in order to remove the pressure of the weight of his body from the fore legs and feet; at the same time, he sets his fore feet to the ground with seeming great pain; his fore parts are extremely hot, the legs considerably swelled, and evidently painful to the animal when touched; a violent fever succeeds, which, if not properly treated, terminates in death, or, if the horse survives the shock, in incurable lameness. On dissecting the legs and shoulders of those horses that have died, after a few days' illness, of this disorder, the blood is generally found extravasated, the parts having a black appearance, especially between the skin and the flesh. The same blackness is likewise observed in the cellular membrane, between the interstices of the muscles and tendons; the texture of the vessels too is destroyed, and their substance mortified.

The following case was communicated to Mr. Clark by a very judicious farrier in London. A gentleman, being eighteen miles distant from London, was anxious to be in town before it was dark. He rode his horse very hard through a deep snow, during a severe frost. When the horse was suppered up, after being well rubbed over, he lay down, and was found in the same situation next morning, but unable to rise, or stand when up. On the third day, both his fore hoofs fell off. This was a founder of the very worst kind.

The excessive coldness of the snow, to which his hoofs and legs had been so long exposed, when they were overheated, produced the effects above related in the case of founder. The violence of the inflammation that had taken place within the hoof had destroyed the texture of the vessels, &c. Hence all manner of connection between the hoof and internal parts of the foot being destroyed, they became loose, and fell off.

This fact, and the reasoning upon it, may, perhaps, serve to explain a remarkable circumstance which happened to a horse in one of the mail-coaches. It took place at the time when there was much ice and snow on the ground. This very spirited animal lost both fore hoofs in the performance of his task, and yet went through to the end of the stage, till which time this cruel circumstance was not discovered, nor any thing beyond a slight degree of lameness in his gait observed by the coachman. The poor animal was, of course, destroyed.

In hunting, when horses are over-heated, and go through deep water, especially if they are obliged to swim, they soon after become faint, jaded, and tired.

FOWLING is a term scarcely known among modern sportsmen: it was formerly used to express the taking of birds by the net; and at present it may not be altogether obsolete in those places where WILD FOWL SHOOTING is much followed, to which article the reader is referred.

FOWLING BAG, OR NET. A bag carried by shooters for the purpose of receiving such game as they may be able to kill—it is too well known to need further description.

FOWLING-PIECE. This extraordinary engine, so essential to the sportsman, has undergone so many alterations, and has experienced so many improvements, as to be scarcely any longer recognizable as the offspring of the original hand-gun, as, in fact, the descendant of that clumsy instrument, which it is supposed was introduced into this kingdom by Edward IV. in the year 1471. We may trace the parent, however, still further back; and in order that this article may be rendered as complete as possible, we will trace the progress of the projectile engine now under consideration, from the earliest period to the present time.

There are writers, who carry the invention of artillery back to very remote antiquity; and, though it does not seem possible to fix upon the precise period of

its introduction, yet, there is every reason to believe it quickly followed the discovery of that extraordinary combustible, gunpowder (see GUNPOWDER). The ingenious translator of the Gentoo Laws, finds fire-arms, gunpowder, and *cannon*, mentioned in that code, supposed at least coeval with Moses. “It will, no doubt, (says he) strike the reader with wonder to be informed of a prohibition of *fire-arms* discovered in records of such unfathomable antiquity; and he will probably hence renew the suspicion which has long been deemed absurd, that Alexander the Great did absolutely meet with some weapons of that kind in India, as a passage in Quintus Curtius seems to ascertain.” There is also, (says Mr. Grose) the following antient testimony to this point in Grey’s Gunnery, printed in 1731. In the life of Appolonius Tyanæus, written by Philostratus, about fifteen hundred years ago, there is the following passage concerning a people of India, called Oxydracæ:—“These truly wise men dwelt between the rivers Hyphasis and Ganges; their country Alexander the Great never entered, deterred not by the fear of the inhabitants, but, as I suppose, by religious considerations; for, had he passed the Hyphasis, he might doubtless have made himself master of the country all round them; but their cities he could never have taken, though he had led a thousand as brave as Achilles, or three thousand such as Ajax, to the assault: for they come not out into the field to fight those who attack them, but these holy men, beloved by the gods, overthrow their enemies with tempests, and thunderbolts, shot from their walls. It is said, that the Egyptian Hercules and Bacchus, when they overran India, invaded this people also; and, having prepared warlike engines, attempted to conquer them: they made no shew of resistance; but, upon the enemy’s near approach to their cities, they were repulsed with storms of lightning and thunderbolts, hurled upon them from above.”

In a work, entitled the *Gunner*, by Robert Norton, and printed in London in the year 1664, the author states that the Uffano reporteth, that the invention and use of *ordnance* (and consequently of gunpowder) took place in the fifty-eighth year of our Lord, and was practised in the “great and ingenious kingdom of China; and that in the maretime provinces thereof, there yet remain certaine peaces of ordnance, both of iron and

brasse, with the memory of their yeares of founding engraved upon them, and the armes of king Vitey, who, he says, was the inventor."

The preceding quotations, however, it must be allowed, are extremely vague, to say the least of them; and may perhaps be regarded rather as the wanderings of a restless imagination than as the sober data of truth. The following extracts may, in all probability, be relied on.

Polydore Vergil, who died in 1555, after noticing the discovery of gunpowder, informs us, that an obscure German invented an *iron tube*, and taught the Venetians the use of *guns* in the year 1380.

The battle of Cressy was fought in the year 1346, and an historian who lived at that time is quoted by Spondanus as affirming that the English greatly increased the confusion the French had been thrown into, by discharging upon them from their *cannon*, hot iron bullets. Three years before the battle of Cressy, the Moors were besieged by the Spaniards in the city of Algeziras; and we learn from Mariana, the Spanish historian, that "the besieged did great harm among the Christians with *iron bullets* which they shot." The same author adds, "this is the *first time* we find any mention of *gunpowder* and *ball* in our histories."—The Earls of Derby and Salisbury are mentioned by Mariana as having assisted at the siege of Algeziras; and as they returned to England in the latter end of the year 1343, it is not an improbable conjecture, that, having been witnesses of the havoc occasioned by the Moorish firearms, they brought the secret into England, and introduced the use of artillery into the English army at the battle of Cressy.

If we are to believe father Daniel, the French had *cannon* in the year 1338; though it does not appear they made any use of it in the battle of Cressy, which did not take place till eight years afterwards. But there is reason to believe that *guns* or *cannon* were known in Germany forty years prior to this period, as in the armoury of Amberg, in the Palatinate of Bavaria, there is a piece of ordnance, on which is inscribed the year 1303.

The Danes are said to have used *guns* as early as 1280, but the account seems more than doubtful. There are passages in the history of English wars, which assert the employment of *artillery* antecedent to the above periods; for instance, if we are to credit John Barbour, Arch-

deacon of Aberdeen, Edward III. had *artillery* in his campaign against the Scots in the year 1327.

In 1339, the Scots used *battering cannon* at the siege of Stirling, which cannon had no doubt been sent them by their French allies. At the siege of Calais in 1347, "*gunners* and *artillers* appear in a manuscript list of the English troops in the Harleian collection. The Earl of Pembroke, who commanded a British fleet in the year 1372, was taken prisoner by a Spanish squadron superior in numbers, and which were (perhaps for the first time) provided with *cannon*. However, half a century afterwards, the English ships of war were provided with very few guns, seldom more than two, and those not mounted so as to be altered occasionally in their direction, a circumstance, the motion of the sea considered, which must have rendered them of little service.

In 1378, Richard II. sent to Brest "two greater and two lesser engines, called *cannons*, and 6000 stone bullets. John of Gaunt, who had the command of the army, attempted to take St. Maloes, but was baffled by the skill of the great Du Gueschin, although, it is said, he had a train of 400 *battering cannon* playing upon the town.

According to Froissart, the Flemings had, in 1382, a tremendous piece of ordnance:—"it was (says he) fifty feet long, and threw wonderfully large stones. Its report was heard five leagues by day and ten by night."

In 1418 iron balls were used for *cannon* in England, since in Rymer there is an order from king Henry V. to the clerk of the ordnance, and John Bonet, a mason in Kent, to cut 7000 stone shot in the stone quarries in that county; but there is reason to believe that the French made use of iron shot prior to this period, since at the attack of Cherbourg, towards the close of the year 1418, the besiegers, commanded by the Duke of Gloucester, were much annoyed by *red-hot balls* fired from the town.

The valiant Earl of Salisbury fell by a *cannon* shot at the siege of Orleans in the year 1428; and was, according to Camden, the first English gentleman "ever slain thereby." The Earl was reconnoitring the town from a high tower on the bridge, when the son of the master gunner of Orleans pointed a cannon at the window and slew him; the ball carried away one of his eyes and his cheek,

and mortally wounded Sir Thomas Gargrave.

The Turks were repulsed at the siege of Belgrade in the year 1437, by the use of artillery, then used for the first time, it is said, in that part of Europe. But the Turks themselves, in the early part of the 15th century, attempted the use of artillery, as we find Mahomet II. employed it in the siege of Constantinople. Gibbon remarks, "Among the implements of destruction, Mahomet II. studied with peculiar care the recent and tremendous discovery of the Latins; and his artillery surpassed whatever had yet appeared in the world. A founder of cannon, a Dane or Hungarian, who had been almost starved in the Greek service, deserted to the Moslems, and was liberally entertained by the Turkish Sultan. Mahomet was satisfied with his answer to his first question, which he eagerly pressed on the artist. 'Am I able to cast a cannon capable of throwing a ball or stone of sufficient size to batter the walls of Constantinople?' 'I am not ignorant of their strength; but, were they more solid than those of Babylon, I could oppose an engine of superior power: the position and management of that engine must be left to your engineers.' On this full assurance, a foundry was established at Adrianople: the metal was prepared; and, at the end of three months, Urban produced a piece of brass ordnance of stupendous and almost incredible magnitude; a measure of twelve palms is assigned to the bore; and the stone bullet weighed above six hundred pounds. A vacant place before the new palace was chosen for the first experiment; but to prevent the sudden and mischievous effects of astonishment and fear, a proclamation was issued that the cannon would be discharged the ensuing day. The explosion was felt or heard in the circuit of an hundred furlongs; the ball, by the force of the gunpowder, was driven above a mile; and, on the spot where it fell, it buried itself a fathom deep in the ground. For the conveyance of this destructive engine, a frame or carriage of thirty waggons was linked together, and drawn along by a team of sixty oxen: two hundred men on both sides were stationed to poise and support the rolling weight; two hundred and fifty workmen marched before to smooth the way and repair the bridges; and nearly two months were employed in a laborious journey of one hundred and fifty miles. A lively philosopher derides

on this occasion the credulity of the Greeks, and observes with much reason that we should always distrust the exaggerations of a vanquished people. He calculates that a ball, even of two hundred pounds, would require a charge of one hundred and fifty pounds of powder; and that the stroke would be feeble and impotent, since not a fifteenth part of the mass could be inflamed at the same moment. "Yet I dare not (says Gibbon) reject the positive and unanimous evidence of contemporary writers; nor can it seem improbable that the first artists, in their rude and ambitious efforts, should have transgressed the standard of moderation. A Turkish cannon, more enormous than that of Mahomet still guards the entrance of the Dardanelles: and if the use be convenient, it has been found on a late trial that the effect was far from contemptible. A stone bullet, of *eleven hundred* pounds weight was once discharged with three hundred and thirty pounds of powder: at the distance of six hundred yards, it shivered into three rocky fragments, traversed the streight, and, leaving the waters in a foam, again rose and bounded against the opposite hill." Mahomet's enormous cannon, however, could only be discharged seven times in one day; it was not long before it burst, killing several of the workmen by the unfortunate explosion.

Two pieces of artillery used at Dieppe, 1442, as represented by Pere Montfaucon, seem ill calculated for service; nor does there appear throughout the century any contrivance to elevate or depress the pieces; a deficiency which must have rendered them comparatively useless. But it was certainly not for want of bulk that the artillery of the age failed in becoming respectable; as in addition to what has been already mentioned, we are told by Monstretel of a piece of ordnance which sent a ball, weighing 500lbs. from the Bastille at Paris to Charenton, in 1477.

Edward IV. had *field-pieces*, when he defeated Sir Robert Wells at Stamford in 1469. "The king (says Leland) sparkled the enemy with his ordnance, slew many of the commons, and thereby gained the victory."

At the battle of Flodden in 1513, the Scots were much superior in ordnance: Borthwic, an engineer of eminence, had the direction of it. Louis of France had sent him to James with a large present of brass cannon, on each side of which

was inscribed “*Machina sum Scoto Borthwic fabricata Roberto.*” This valuable train of artillery fell into the hands of the Earl of Surrey after the battle of Flodden, together with seven “*faire culverines,*” called the Seven Sisters.

In process of time, a kind of light cannon, called a *culverin*, sometimes carried by two men, and sometimes by only one, was introduced. These were used by the Switzers at the battle of Maorat, where 10,000 of them were so armed. This weapon seems to have been the immediate parent of the musket, and was placed on a rest to be discharged.

Dr. Watson says, that “Artillery was used from the time of Edward III. and purchased from abroad by all our successive kings; it seems, however, extremely strange, that none of our workmen attempted to cast cannon till the reign of Henry VIII. when, in 1521, according to Stowe (Camden says 1535) great brass ordnance, as *cannon* and *culverines*, were first cast in England by one John Owen, they formerly having been made in other countries. Whether this man did not succeed, or died before 1543, is not mentioned; but in that year Stowe remarks, the king employed two aliens as his *gun-founders*, viz. Peter Bawd, a Frenchman, and a maker of great ordnance; and Peter Van Collen, a gunsmith. It has been remarked of Queen Elizabeth, that she left more brass ordnance at her death than she found of iron at her accession to the throne. This must not be understood as if gun-metal was in her time chiefly made of brass; for the term brass was sometimes used to denote copper; and sometimes a composition of iron, copper, and calamine, was called brass; and we at this day commonly speak of *brass cannon*, though *brass* does not enter into the composition used for the casting of cannon. Aldrovandus informs us, that one hundred pounds weight of copper, with twelve of tin, made gun metal; that if, instead of twelve, twenty pounds weight of tin were used, it made bell metal. The workmen were accustomed to call this composition metal or bronze, according as a greater or a less proportion of tin had been employed: some individuals, he says, for the sake of cheapness, used brass or lead in the room of tin, and thus formed a kind of bronze for various works. The metal of which the ancients cast their statues was by Pliny said to be composed in the following manner:—They first melted a quantity of copper;

into this melted copper they put a third of its weight of old copper, which had been long in use; and to every hundred pounds weight they added twelve pounds and a half of a mixture of equal parts of lead and tin.

“Brass cannon are much dearer than those made of iron, and have this disadvantage, that at the time of explosion the report is so much louder as to occasion a tingling in the ears of persons on ship-board, which for a time takes away the faculty of hearing. Cannon might be cast of copper alone, but the mixture of tin and copper is harder and denser, and less liable to rust than pure copper, and upon these accounts it is preferable to copper. Tin melts with a small degree of heat; copper requires a very great heat to melt it: copper and tin mixed melts much easier than pure copper; and upon this account also a mixture of copper and tin is preferred to pure copper, not only for the casting of cannon, but for statues, &c. for pure copper, in running through the various parts of the moulds, would lose so much of its heat as to set before it ought to do.”

The musket or hand-gun, as we have already observed, was evidently the immediate forerunner of the fowling-piece; and Edward IV. may be justly considered as the first who introduced hand-guns into England. This monarch landed at Ravenspurgh in Yorkshire in the year 1471, bringing with him, among other forces, three hundred Flemings, armed with “*Hange Gunnes.*” This is fifty years before the date generally assigned for their introduction; Mr. Anderson, the Rev. Mr. Lamb, and divers other writers placing that event in 1521 at the siege of Berwick, where they were called *hand-cannon*. The hand-gun used in England was a short piece, as appears from the statute of thirty-third of Henry VIII. whereby it was enacted, that “no hand-gun should be used of less dimensions than one yard in length, gun and stock included.” The haque-but or hag-but was a still shorter piece; by the above statute, it might not be under three-quarters of a yard long, gun and stock included as before. This piece is supposed by some writers to have been called a haque-but, from its butt end being hooked or bent, like those now used; the stock of the hand-gun being nearly straight. There were also guns, called demi-haques, either from being less in size, or from having the butts less curved, and likewise

a sort of pistol named a *dag*. The harquebuss is by Fauchet derived from the Italian *arca bouza*, or the bow with the hole ; and is the most ancient arm mounted on a stock. It does not appear that harquebusses were originally of any particular length or bore. All the kinds of fire-arms were first fired with a match, and afterwards some of them with the wheel lock. The former, by a spring, let down a burning match upon the priming in the pan ; and the latter was a contrivance for exciting sparks of fire by the friction of a notched wheel of steel which grated against a flint ; these wheels were wound up with an instrument called a spanner. The balls were carried in a bag or purse, the powder in a horn or flask, and the priming, which was of a finer sort of mealed powder, in a touch-box : this powder was termed serpentine, from the part of the matchlock which contained the match being denominated the serpent. The petronel or poitronel was, according to Fauchet, the medium between the harquebuss and the pistol. Nicot, in his dictionary, defines it as a species of harquebuss shorter than the musket, but of a greater calibre, which, on account of its weight, was carried on a large bauldrick worn across the shoulders like a sash, and when fired was rested on the breast or the shoulder of the person who used it.

The musket was a heavier kind of harquebuss, carrying also a larger ball, and probably introduced owing to the trivial execution done by pieces of small calibre. Sir Thomas Kellie, in his *Art Militaire*, published in the year 1621, says the barrel of a musket should be four feet in length, the bore capable of receiving bullets twelve of which weigh one pound. Muskets were so heavy as to require a fork, called a rest, to support them when presented in order to fire. These rests were of different lengths, according to the heights of the men who were to use them ; they were shod with sharp iron ferrules, for sticking them in the ground ; and, even on the march, when the musket was shouldered, carried in the right hand, or hung upon it by means of a string or loop tied under the head. Sometimes these rests were armed with a contrivance called a *swine's feather*, which was a sort of sword blade or tuck that issued from the staff of the rest at the head ; this being placed before the musketeers when loading, served, like the stakes placed before the archers, to keep off the cavalry : these

preceded the use of the bayonet, the invention of which, originated in the soldiers sticking the handles of their daggers into the muzzles of their pieces when they had discharged all their ammunition. Father Daniel says the regular introduction of bayonets took place in France about the year 1671, and that the first corps armed with them was the first regiment of fusileers raised that year. The term bayonet was derived from these weapons being first made at Bayonne ; they were called by the French bayonets *à manche*, or bayonets with handles. There are many of them in the small armoury of the Tower of London. The modern implements were termed bayonets *à douille*, or bayonets with sockets.

If Brantome is to be credited, it was the Duke d'Alva who first brought muskets into use in the armies, when, during the reign of Philip II. he went to take upon him the government of the Low Countries, in the year 1567 ; but that only means he brought them more into fashion than they were prior to that period, and that, until then, they were rarely used, at least in the field. The Spaniards in the time of Philip II. caused their muskets to be made of a very great calibre, and such as a strong and vigorous foot-soldier might carry ; but they were so heavy that they could not be presented without the aid of staves shod with iron, with a fork at the top, as a prop to sustain the end of the musket. Muskets were fired with matchlocks ; and musketeers, of the reigns of James and Charles I. carried their powder in little wooden, tin, or leather cylindrical boxes, each containing one charge. Twelve of these were fixed to a belt across the shoulders, and were called *bandeleers*.—This contrivance seems to have been borrowed from the Dutch or Walloons.—To prevent the matches from being seen in the night, small tubes of tin or copper, pierced full of holes, were invented, it is said, by a Prince of Orange, probably Prince Maurice.

The *caliver* was a lighter kind of musket with a match lock, and was made to be fired without a rest. Pecke, in his *Desiderata Curiosa*, gives the price of a caliver and its accoutrements, as paid in Queen Elizabeth's time by the Sheriff of Lancashire in 1584, for the use of recruits raised for the Irish service—which was, the caliver, furnished with flaske, touch-box, laces and moulds, thirteen shillings and sixpence.

Charles I. in 1629 adopted measures for bringing about an uniformity in the size and fashion of the armour and arms, a circumstance which had hitherto been neglected.

In the reign of James II. the first step was taken towards the abolition of the use of pikes in England by the practice of sticking the dagger into the muzzle of the musket in order to protect the musketeers from being charged by the cavalry immediately after they had fired. This manœuvre, which was adopted by the French in 1671, and taken from them into our service some years after, was confined to the grenadiers only, and was the origin of the bayonet. In a book of Exercise for Horse, Dragoons, and Foot, printed by authority in the year 1728, the bayonet of the present fashion is described.

The following anecdote respecting that weapon is mentioned to have happened in one of the campaigns of king William III. in Flanders. In an engagement, where there were three French regiments, whose bayonets were made to fix after the present method (a contrivance then unknown in the British Army) one of them advanced against the 25th regiment with fixed bayonets: Lieutenant Colonel Maxwell, who commanded it, ordered his men to screw their bayonets into the muzzles to receive them, thinking they meant to decide the affair point to point; but, to his great surprise, when they came within a proper distance, the French threw in a heavy fire, which, for a moment, staggered his people, who by no means expected such a greeting, not conceiving it possible they could fire with fixed bayonets: the British regiment, however, recovered itself, charged, and drove the enemy out of the line. Notwithstanding this instance of the utility of the *socket* bayonet, it seems that the old bayonets underwent a mutation or two before they arrived at their present form: one of them was a couple of rings, fixed into their handle, for the purpose of receiving the muzzle of the piece, like the socket now in use, by which means the soldier was enabled both to fire and load his musket without unfixing his bayonet.

Thus the bayonet superseded the pike, the match-lock was exchanged for the *snap-lance*, the original name of the present lock; or, at least, the application of the flint-lock to the musket (after the invention of the bayonet) gave it the name of the snap-lance, as applied to the whole.

This improvement took place in the reign of William III. but the change does not appear to have been sudden; it was accomplished by degrees, and therefore an exact period for it cannot be positively assigned.

Hence we perceive the origin of that essential article to the sportsman—the *fowling-piece*; and as the changes in the form and make of the musket have been progressive, the fowling-piece has experienced still greater improvements, and has perhaps nearly, if not altogether, reached the acmé of perfection.

There are few persons, sportsmen or others, who have not heard of the superior excellence of *Spanish barrels*; but whether they ever deserved the character they acquired, and the preference given them, is somewhat doubtful. Spanish guns always were, and still continue to be, very awkward looking instruments; and from the circumstance of the same person manufacturing the whole gun, barrel, lock, stock, &c. it is not likely that the same perfection can be attained, as the English fowling-pieces display, the manufacture of which is judiciously subdivided among several persons. The Spanish iron, especially that of Biscay, was supposed to be the best in Europe; and the Spaniards formerly possessed the reputation of forging and boring their barrels with more care than other nations.

The barrels made at Madrid were said to be composed of the old shoes of mules and horses collected for the purpose, and we are gravely told, that “some idea may be formed of the very great purity to which the iron was brought in the course of the operation, when it is known, that, to make a barrel which, rough from the forge, weighs only six or seven pounds, they employ a mass of mule shoe iron weighing from forty to forty-five pounds, so that, from thirty-four to thirty-eight pounds are lost in the heatings and hammerings it undergoes before it is forged into a barrel.” However, of the Spanish barrels, those only that were made in Madrid were accounted truly valuable; and in consequence of this predilection, numbers were manufactured in various parts of Spain and also in other countries, and the marks of the Madrid gunsmiths surreptitiously put upon them: nor have I the least doubt, that most of the barrels, of late years sold in this country as the workmanship of Spain, were manufactured in Birmingham. There are, however, many persons still to be found who en-

ertain a very high opinion of the Spanish barrels ; and those made by men who have been dead many years are held in the greatest estimation. A writer, speaking of Spanish barrels, says the true ones are made of iron worn and beaten for a long time, as heads of nails in the shoes of mules, which travel with a slow and incessant pace along the hard roads ; but that a very small proportion of the great quantity of Spanish barrels sold in all parts of Europe can have this advantage. He adds, that the Corsican iron possesses a toughness nearly equal to that of the prepared iron in Spain ; and the metal of the Corsican barrels, well made, is little inferior to the generality of Spanish ones.

At all events, whatever may be the material from which the barrel is manufactured, whether from Spanish mule shoe iron or otherwise, the first object in the choice of a fowling-piece ought to be *safety* ; and, whatever might be the weight of the barrel, the metal should be so disposed as to prevent even the remote probability of bursting. In double guns, the stoutness of the barrel is indispensable, if the shooter has any regard to his own safety ; for, in light double-barrel pieces, the firing of one will frequently loosen the charge of the other barrel ; and should the shot be so shaken as to leave the powder a few inches, and the second barrel fired with the muzzle pointing downwards, it will most likely burst. The lower or breech end of all barrels should be very strong ; it is of little consequence how thin the muzzle end may be : it is the instantaneous explosion which ensues on the ignition of the powder which puts the barrel to the test ; and the moment the charge commences its progress up the barrel, as it were, all danger of bursting has passed away.

It has been supposed that barrels forged from steel are lighter and safer, and shoot stronger, than any others ; but it has been satisfactorily ascertained that, where steel was used, the barrel neither welded nor bored so perfectly, as when iron alone was employed. There are various kinds of barrels, which pass under different denominations, such as twisted-stub barrels, wire-twisted barrels, Damascus barrels, and common barrels. Twisted stubs are old horse-shoe nails twisted together ; there are also iron-twisted, inferior to the former. Wire-twisted are stubs drawn into wire, and then twisted and formed into the barrel. Damascus barrels are iron and steel curled together,

which gives the barrel a beautiful appearance. And “ I have reason to believe (adds a writer on the subject) not only from experience, but also from the opinion of an excellent gunsmith, that wire-twisted stub barrels are to be preferred to all other.” Damascus barrels are inferior even to common twisted stubs ; though, as they bear a foreign name, and as the peculiar curling of the iron and steel gives them a pleasing, and indeed a beautiful, appearance, they have of late been in request : the English gun-makers found it inconvenient to import a sufficient number ; in fact, it was impossible, and they therefore did not hesitate to manufacture Damascus barrels, and not more than one real barrel of this sort out of a hundred, perhaps a thousand, is to be met with. It is well known that the temper of the Damascus scimitars is superior to any other ; and there is every reason to believe that the originals of what are called Damascus barrels were absolutely manufactured at the place, the name of which they bear : a real Damascus barrel occasionally reaches this country, generally through Russia ; and the few which have fallen under the observation of the writer, are certainly much superior to those manufactured in England, and distinguished by the same appellation.

In continuation of this subject, it may be observed that no fowling-piece should be put into the hands of a sportsman which has not undergone the most incontestible scrutiny or proof. Many barrels have burst, after having gone through the Company's or Tower proving house, and received the customary mark as a guarantee of their safety ; and in all probability the only mode of ascertaining the indisputable safety of a barrel is by water-proof.

The old mode of proving barrels, as used in the king's proving house, was to load the barrel with powder equal to the weight of the ball which fitted the bore ; but this has been altered by an act of parliament obtained by the Birmingham Proof Company ; and also at the Company of Gun-makers' Proof-house in London ; by which the proof is reduced to nearly one third less of powder. To say nothing of any indefinite satisfaction thus to be derived, all fowling-pieces should be submitted to the test of water-proof ; that is, water should be forced into the barrel with the proper apparatus. This process will discover the slightest defect, by the

oozing through of the water which is forced down the barrel. Some idea may be formed of the nature of this proof from the following :—That water is the most fluid penetrating body next to fire, and the most difficult to confine, has been satisfactorily proved by a variety of experiments. A vessel through which water cannot pass may be said to be capable of retaining any thing. It may be objected, indeed, that syrups, oils, and honey, leak from some vessels through which water will not pass; but this is far from being the result of the greater tenuity or fineness of their parts; it is owing to the resin with which the wood of such vessels abounds, which oils and syrups have a power of dissolving; so, that these fluids, instead of finding their way, may be more properly said to *eat* their way through the vessels in question. However, water will at last find its way even through these; for it is known to escape through vessels of every substance, glass only excepted. Other bodies may be found to make their way out more readily indeed; as air, when it finds a vent, will escape at once; and quicksilver, because of its weight, will quickly penetrate through whatever chinky vessel confines it: but water, though it operates more slowly, yet always finds a more certain issue. As, for instance, it is well known that air will not pass through leather, which water will readily penetrate. Air also may be retained in a bladder, which water will readily ooze through. And those who go to the greatest degree of precision pretend to say that it will pass through pores ten times smaller than air can do.—Be this as it may, we are very certain, that its parts are so small that they have been actually driven through the pores of gold. This has been proved by the famous Florentine experiment, in which a quantity of water was shut in a hollow ball of gold, and then pressed by a huge force with screws, during which the fluid was seen to ooze through the pores of the metal, and to stand like a dew upon its surface.

By the old method of proving, a barrel was obliged to stand three days after proof before it was examined as to its safety; but proof with water is infinitely more efficacious, and consequently more satisfactory.

Amongst others who have expressed their opinions on the subject under consideration is one Ezekiel Baker, whose “Remarks on Rifle Guns” deserve particu-

lar notice, not on account of any new or extraordinary light they throw on the matter, but from a quaintness or affectation of peculiarity which pervade them throughout. On the subject of proving he observes, “I proved a pair of double barrels on the percussion (see the article PERCUSSION LOCK) principle; and although they had been proved at the Company of Gun-makers’ Proof house, both in their single and double state, had stood the proof and were marked as sound barrels—had been afterwards proved by me in the usual manner, both regular and water-proof, yet, when I proved them by the percussion principle, both barrels bulged, were much shivered, and were consequently spoiled.

Another pair (continues Baker) had undergone the strictest proof at my proof-house, and such as would be generally considered sufficient to justify the strongest recommendation for safety; yet, on trying them by the detonating principle, the result was the same—both barrels were seriously injured.

February 22, 1823.—I have this day tried another pair of barrels (says Baker) which had undergone the regular proof, and which I had absolutely fitted to the stock for sale, by specific order—both barrels failed.

These barrels (continues Baker) had stood every proof which is usually considered safe; and yet, from the suddenness with which the powder is ignited by the detonating principle, all the barrels failed. Consequently, the result of these experiments convinces me, beyond any theoretical views entertained by others, that the proof of double-barrels with percussion locks can only be satisfactorily proved by the detonating principle. Every other proof, however it may appear to pass the ordeal of safety, is not a sufficient guarantee.”

These observations, if they amount to any thing, merely go to prove the extraordinary efficacy of the percussion principle—they prove indeed (in the first place perhaps the ignorance of Baker himself, in making use of a much larger quantity of gun-powder than was any way requisite) that a much smaller quantity of gunpowder than usual is amply sufficient for the charge of a fowling-piece fitted up on the percussion principle; and they prove also, that when the customary quantity of gunpowder used in proving is ignited by means of the percussion plan, that it thus acquires force sufficient

to injure, if not to burst, barrels, which have endured the severity of water-proof; but they by no means shew that the proof by water is not sufficient to answer, and that fully too, all the purposes of safety in the use of the fowling-piece. There is nothing equal to the proof by water, and no other mode which can give such complete satisfaction. The fact is, the rapidity of ignition by percussion increases the elastic force of the gun-powder to such a degree that no gun barrels are able to resist it.—Again we refer the reader to the article PERCUSSION LOCK.

Among the many improvements that have been made in the fowling-piece, we must notice the *length of the barrel*. At a period not very remote, it was considered that a great length of barrel was indispensable, if the shot was to be driven any considerable distance; and, pursuing this train of ideas it was taken for granted that the longer the barrel of the gun, the further the shot would be thrown; and hence we see in many ancient halls and farm houses gun barrels of such a length that it is not without great difficulty they can be presented from the shoulder; some, in fact, require a rest, after the manner of the old harquebusses, when they are to be pointed at any object. The subject is scrupulously investigated in Johnson's Shooter's Companion, the author of which remarks—"The length of the barrel is a matter which is involved in doubt, though abundant evidence has been obtained to prove that the antiquated notion of long barrels carrying the farthest is completely erroneous. After a great number of experiments I have found, that a barrel twenty-eight inches long, of the common fowling-piece calibre (five eighths of an inch diameter) shoots fully as strong, if not stronger, than any other greater length; though the difference between twenty-six and twenty-eight or even thirty inches, is not very great; but for any increase of length beyond thirty inches, the difference, or the decrease of force, would very much surprise any person who had never witnessed the experiment. I have shortened five different barrels (says he) gradually, inch by inch, for instance, and the result has invariably been the same; and, in these experiments, great pains were taken in regulating the charge, so that, in this respect, no perceptible variation could take place. Nevertheless, though a barrel twenty-six inches long (I never tried one shorter) may impel the charge with more force

than a greater length, yet I prefer a barrel somewhat longer, as it is pleasanter to load, and the aim may be much better taken with it; yet, for my own choice, I would never exceed thirty inches.

At first sight it may be asked, how it happens that a long eighteen-pounder carries farther than a shorter cannon?—To which it may be answered, that it is possible an increase of length may be added with advantage, to the longest eighteen pounder in the service; since, on comparison, taking into consideration the difference of the calibre, a fowling-piece barrel twenty-six inches in length, is proportionably longer than any cannon whatever.

If the bore, or calibre, of the fowling-piece be made extremely wide, it will require a greater charge, and will, of course, admit of a greater length of barrel."

According to Mr. Robins, gunpowder fired in any space acts nearly in the same manner as a quantity of air would do, which was condensed a thousand times more than the common air we breathe; and which, in that condensed state, filled the same space that was taken up by the unfired powder. Hence it follows, that the pressure of the powder on the shot becomes weaker and weaker, as the shot is impelled before it; for, as the shot is impelled forward, the inflamed powder occupies more space, and consequently its elasticity is lessened. In short, it is quite clear, if we reason upon the subject, that, in order to attain the greatest possible force, the shot should leave the muzzle of the gun the moment that the elastic fluid, generated by the explosion of the powder, has acquired its greatest elastic force, or power of impulsion; if, after this precise instant, the shot has still to move farther up the barrel, it will have to contend against the lateral action, or friction, of the inner surface, as well as be directly opposed to the atmospheric air in front; and therefore a length of barrel beyond that already stated cannot accelerate, but must necessarily retard, the flight or force of the shot. But, to ascertain the precise point of perfection in this respect will be found a very difficult matter, if it be not altogether impossible; as a variety of causes will be found to operate against what—in the absence of a better term—may be called mathematical demonstration; amongst the most prominent of which may be mentioned the quality of the powder, its great sus-

ceptibility of variation from the influence of the weather, and the state of the atmosphere at the time of making the experiment. Sufficient, however, has been satisfactorily shewn to prove that long barrels are detrimental to the force of the shot; and that they consequently produce the very reverse of what they were intended to effect.

*Boring of Barrels.*—I shall not attempt to describe the process of boring gun barrels, as this work is intended not for the mechanic, but the sportsman; besides, in every thing of this sort, five minutes' inspection would do more than a volume of words; yet, as the well shooting of a fowling-piece materially depends upon the boring of the barrel, we shall state what kind of bore or cylinder we have found to throw the shot with the greatest force, as well as with the greatest regularity. However, thus much may be stated at the outset, viz. that the boring of barrels is very imperfectly understood, and it is no uncommon occurrence for a gun upon which every possible care and pains have been bestowed in the boring not to shoot so well as an ordinary or common barrel. Those makers, however, who are careful of their reputation, will seldom turn out a gun with the shooting of which they have not been previously satisfied; though it often happens that this is not accomplished without considerable trouble. The difficulty arises from the want of a positive rule for boring, which, however, is perhaps unattainable, as the method by which one indifferent shooting gun is rendered unobjectionable or excellent will very often fail when applied to another:—hence, the gun maker, in order to attain his object, is under the necessity of first trying one method and then another till he ultimately succeeds. It is true, gun makers, when speaking on the subject of boring barrels, assume an air of mysterious importance, and, by significant shakes of the head and broken sentences, give you to understand that the true and correct method of boring gun barrels, is a secret which remains with them and them only.

The bore which has given the writer the most satisfaction, and that which he now uses, is, for a very short distance from the breech, a trifle wider than the remainder of the barrel; this increase of width should be sufficient merely to be perceived when forcing down the wadding, which will of course slide easier in the widened part. Many prefer a perfect cylinder.

The *Breeching* of the fowling-piece has been, and very justly too, considered of essential importance; this must always be the case with the flint-lock; but is, we are inclined to think, of less consequence where the percussion principle is used, particularly when the gun is fired by a copper cap, placed upon a pin or touch hole, screwed into the upper part of the breech, or even when this is screwed into a collar laterally, which forms, as it were, part of the breech; but where percussion plans are used, which force the flame produced by the explosion of the priming into the ordinary touch-hole, as used in the flint lock, the proper or best form of the breech must be as essential in the one as the other. As to the best form of the breech many opinions will be found to exist: there are few gunsmiths, who will not tell you they have made some improvements in this part of the fowling-piece; and, of course, every one of these breech-improvers will recommend his own plan. It would perhaps be difficult to ascertain which is the best form of the breech, as a number of trifling variations have been effected without any perceptible difference.

The *Elevated Breech* is an invention of a recent date; and consists of a sort of broad rib, which runs along the top of the barrel, thicker at the breech end and tapering to the muzzle: by this contrivance the muzzle acquires an elevation, and the shot is consequently thrown higher; for those, therefore, who are apt to shoot under or below the object, the elevated breech is to be recommended.

For the *Touch Hole* platina is to be preferred—it resists the action of fire better than gold.

Of the *Lock* little need be said. There are various trifling alterations in this essential article, according to the notions of different makers, which are perhaps equally entitled to consideration; yet, let the principle be what it may, the workmanship should always be of undoubted goodness or excellence; and a perfectly good lock will not only give the most unqualified satisfaction, but will be found at the end of twenty years (with proper care) as good as the first day it was used; while an indifferent lock will be constantly out of repair, and very unsatisfactory to the owner; and, by the end of the first season, it will have cost as much, in all probability, as the price of a lock of superior workmanship.

The *Stock* of the fowling-piece next

presents itself, and is perhaps an object which demands more consideration than is generally bestowed upon it. Supposing the piece to be of superior workmanship, and to shoot in the best possible manner, it will be found extremely unsatisfactory, if it be not stocked to suit the person who uses it: the fowling-piece, therefore, should be stocked the exact bend and length to suit the owner; at the same time, it should be properly *laid off*, a circumstance to which many gunsmiths pay not the least attention: many indeed will be found who are altogether ignorant of the subject. The Birmingham gun-makers never pay the slightest attention to this particular; and the immense number of fowling pieces which are annually vomited forth from this great and general manufactory, and spread all over the kingdom by means of spurious auctioneers, and professed swindlers, are never to be depended on: they are got up in such a manner as to appear well to the eye of a superficial observer, and are sold uncommonly cheap; yet they should be received with caution; it is true, a tolerable article may be sometimes met with amongst the many thousands which are yearly sent forth; but they are always to be suspected, and are utterly unworthy of the attention of the sportsman. What is meant by the term *laid off* is that peculiar form or method of mounting the stock, so as to bring the upper surface of the barrel in a direct line with the eye of the shooter. We would strongly advise sportsmen never to purchase a fowling-piece which they have not tried, and with the shooting of which they are not perfectly satisfied. However, in the trial of the fowling-piece, and indeed in its general use, particular attention should be paid, in the first instance, to ascertain the quantity of powder and shot with which it shoots the best, and afterwards in making a point of using these well ascertained proportions. On trial, it will be found that all guns shoot strongest the first discharge; or, in other words, when they are perfectly clean; and that the force decreases in exact proportion to the piece becoming foul; hence the necessity of occasionally wiping out the barrel during a long day's shooting. There is also (as already observed) a certain proportion of powder and shot which will exactly suit every fowling-piece: if a piece be over-loaded with powder, the shot will scatter very much, and but few pellets will strike the object; whereas, if

an insufficient quantity of powder be used, the shot will not be driven with sufficient force. Yet, it is more than probable that a trifling variation will be found in all guns; or, to speak more plainly, it will be a difficult matter to find two pieces, though of the same length and calibre, which require precisely the same charge. A very good method of ascertaining the load for the fowling-piece is by firing at sheets of paper at given distances, and the progressive result will guide the shooter in the increase or decrease of either the powder or shot, or both.

On investigation it will probably be found that the general error in loading the fowling-piece, is in using too much powder, which not only very much scatters the shot, but renders the recoil almost insupportable:—it is quite a mistaken notion to suppose that a distant object will be better reached by a large load of powder, or that the force of the shot is thus increased; as it will be found, on experiment, that those pellets which strike the mark are not so strongly driven, as when a reduced, but a correct, proportion of powder is used, to say nothing of the scattering of the shot, by which a small object will generally be missed.

In the choice of a fowling-piece, the sportsman should, in the first place, consider the weight he can conveniently carry, strength being a most essential point to shooting as well as to the safety of barrels. After the weight of the barrel has been fixed upon, the bore and the length should be regulated accordingly; and perhaps a narrow, is preferable to a wide, bore.—If the bore be wide, and the weight limited, the barrel must be weakened in consequence. The bore or calibre which takes seventeen balls to the pound is perhaps the best calculated for general use; but, supposing the weight of the barrels be confined (we are speaking of double guns) to four pounds or four pounds and a half, (which is a good and proper weight for barrels,) the bore of which takes seventeen balls to the pound, if barrels of the same weight are made three fourths of an inch in the bore, they are then, not only much reduced in strength and rendered unsafe, but do not shoot so well for want of a due proportion of metal according to the size of the bore; besides, a wide bored double gun, unless made excessively heavy, is very unpleasant to use, as it must be loaded according to its bore, and, for want of sufficient metal, it recoils violently; when, on the

contrary, barrels of a less bore (seventeen or eighteen balls to the pound, for instance) the same weight as the wide bored ones, will shoot very well and be perfectly safe. *Strength* is essential to barrels; yet, a fowling-piece unnecessarily heavy is by no means to be recommended; that is, heavier than the sportsman can conveniently manage; since, if he becomes overpowered with weight and consequent fatigue, the pleasure otherwise arising from the charming diversion of shooting is supplanted by vexation and disappointment. If the weight be limited, the shorter the gun is, of course, the stronger it will be; and there is no weight, at least that a sportsman would choose to carry, that can improve the shooting of barrels above two feet four, or two feet six inches long. There are many sportsmen, particularly of the old school, who cannot prevail upon themselves to think that a short gun (two feet two, or two feet four for instance) will shoot as strong as one of a greater length (two feet eight, or two feet ten); yet such, on repeated trials, has been found to be the case.

For the safety and also for the satisfaction of sportsmen, it may be necessary here to remark, that where the *copper cap* is employed for the purpose of priming, the pin or touch hole should be examined once or twice during the season, I was not aware (observes the author of the *Shooter's Companion*) of the imperious necessity for this examination till some months ago: a brother sportsman informed me his pin or touch hole peg had blown out, and struck him on the forehead. This circumstance appeared somewhat alarming; and I immediately unscrewed the

touch-hole of the fowling-piece which I had used, without alteration, for two successive seasons. To my surprise, I found the bottom or screw part of them much worn by the action of the fire of the percussion priming, and in time, there is little doubt, they would have blown out. A supply of these touch-holes, therefore, should accompany every percussion gun, and the old ones should be removed as often as occasion may require, which will, of course, depend on the quantity of shots fired.

Let it be impressed on the mind of the sportsman, that cleanliness in the fowling-piece is an object of the first importance. The bursting of barrels arises, in nineteen instances out of twenty, from the piece having been kept in a filthy state. Scarcely any gun, however inferior the materials may be of which it is composed, if properly loaded and kept clean, will burst; but, whenever the inner surface of the barrel is suffered to become corroded, so as to form specks of rust, the gun is never afterwards to be depended on. Superficial rust amounts to nothing; but when a speck of rust is allowed to eat away the inner surface, moisture will always lodge in that particular spot when the gun is cleaned: thus corrosion continues to weaken the already injured part, till bursting becomes the inevitable consequence. Shot getting loose, as before noticed, may produce the same effect; and the same remark will apply should the muzzle become stopped with dirt or snow; so that, on every view of the case, too much attention cannot be bestowed on an instrument so indispensable to the delightful recreation of shooting.

**FOX.** This animal is a native of every quarter of the globe, and is of so wild and savage a nature that it is almost impossible fully to tame him. He is esteemed the most sagacious and most crafty of all beasts of prey. The former quality he shows in his mode of providing himself an asylum, where he retires from pressing dangers, dwells, and brings up his young; and his craftiness is evident from his schemes to catch geese, hens, pheasants, partridges, and all kinds of small birds. The fox, when it is possible, fixes his abode on the border of a wood, where he can listen to the crowing of the neighbouring village cocks, and the cries of the poultry. He scents them at a distance; he chooses his time with judgment; he conceals his road as well as his design; he slips forward with caution, sometimes even trailing his body; and seldom makes a fruitless expedition. If he can leap the wall, or creep in underneath, he ravages the court yard, puts more to death than he can eat, and retires slowly with his prey, which he either hides in the immediate vicinity, or carries off to his kennel.

Lanius borealis drawn by Mr. B. F. Edwards

## F O X

In a very short time, he returns for more, which he disposes of in the same manner, though perhaps in a different place. In this way he proceeds till the progress of the sun, or some movements perceived in the house, warn him that it is time to suspend his operations and to retire to his den. He hunts the young hares; seizes old ones on their seats; digs out the rabbit from its hole; discovers the nests of pheasants, &c. and will seize the sitting bird;—the Fox will draw up to and set a partridge or a pheasant as steadily as a well trained pointer; though he will not keep his point so long, as the moment he conceives he has ascertained the situation of the bird by his nose, he endeavours to seize it:—in fact, he will destroy a very considerable quantity of winged game, where rabbits are not plentiful. He is exceedingly voracious, and when other food fails him, he will seize and devour rats, mice, serpents, lizards and toads; of these he destroys great numbers, as well as great quantities of the chafer beetle. When urged by hunger, he will eat roots, insects and vegetables; and the foxes near the coast will devour crabs, shrimps, shell fish, as well as dead fish, and other marine substances which the tide occasionally throws upon the shore. In France and Italy they do incredible mischief by feeding upon the grapes, of which they are said to be excessively fond.

Buffon informs us that the fox sometimes attacks bee-hives, and the nests of wasps, for the sake of what he can find to eat, and that he frequently meets with so rough a reception as to force him to retire that he may roll on the ground and crush those that are stinging him; but having thus rid himself of his troublesome companions, he instantly returns to the charge, and obliges them at length to forsake their combs, and leave them to him as the reward of his victory. When pressed by necessity, he will devour carrion. Buffon one evening suspended on a tree, at the height of nine feet, some meat, bread and bones. The foxes had been at severe exercise during the night; for next morning the earth all round was beaten, by their jumping and running, as smooth as a barn floor.

The first year, the fox is called *a cub*; the second, *a fox*; the third, *an old fox*. His tail is called the *brush*, and his excrement the *billiting*. The female has from three to six at a litter: the cubs are produced in April and May.

As the fox makes war upon all animals, so all others seem to make war upon him. The dog hunts him with peculiar acrimony; the wolf is still a greater and more necessitous enemy, which pursues him to his very retreat. But the fox is not hunted by quadrupeds alone; for the birds, who know him to be their mortal enemy, attend him in his excursions, and give each other notice of the approaching danger. The crow, the magpie, &c. attend him as he proceeds, hovering and chattering, and thus the sportsman sometimes recovers the chase, which, but for these signals, would have been inevitably lost. So that it is the fate of this petty plunderer to be detested by every rank of animals: all the weaker classes shun, and many of the stronger pursue, him.

## F O X

The fox, of all wild animals, is most subject to the influence of climate. The generality of foxes are of a brown red colour, but in the colder countries round the pole, the foxes are of all colours, black, blue, grey, iron-grey, silver-grey, and white; these variations, however, proceed from the season of the year, as, for instance on the coast of Labrador, the fox, which is grey in summer, will become white in winter, thus accommodating itself to the state of the country, as it were, and assuming the colour of the snow by which it is surrounded. The common kind, however, is more universally diffused than any of the others, being found in Europe, in the temperate climates of Asia, and also in America; they are seldom met with in Africa. There are three varieties of this animal in Great Britain; and these are established rather upon a difference of size than of colour or form. The greyhound-fox is the largest, the tallest, and the boldest; and is chiefly found in the mountainous districts and the hills of the north. The mastiff-fox is less, but more strongly built; the cur-fox is the least of the three: but generally affords the best diversion.

The fox prepares for himself a den, under ground, to which he retreats in cases of danger; but he frequently prefers forming himself a place of repose above ground, which is called a *kennel*, and in which he spends the day, if undisturbed. Foxes grow till they are eighteen months old, and live thirteen or fourteen years.

Of all animals the fox has the most significant eye; by which is expressed every passion of love, fear, hatred, &c. He is remarkably playful; but, like all savage creatures, half reclaimed, will, on the least offence, bite even those with whom he is the most familiar. He languishes when deprived of liberty; and if kept too long in a state of confinement, will frequently die of melancholy. When abroad, he is often seen to amuse himself with his fine bushy tail, running occasionally for a considerable time in circles to catch it. In cold weather, he wraps it round his nose. The fox has a broad head, a sharp snout, a flat forehead, erect ears, eyes obliquely seated. He has a great resemblance to the dog, especially in his internal parts; his head, however, is larger in proportion to his body, his ears shorter, and his eyes differently placed.

In Japan, where the fox is very common, the natives believe him to be animated by the devil; and their historical and sacred writings are filled with strange accounts respecting him.

The smell of the fox is proverbially offensive; and is supposed to proceed, as in many other quadrupeds, from glands situated near the tail. The rank or general smell of the fox so exactly resembles the *root of Crown Imperial* as not to be distinguished from it. He has a yelping kind of bark, which consists of a quick succession of similar tones, at the end of which he generally raises his voice like the cry of the peacock. In winter, and particularly during frost and snow, and when he goes to clicket, he yelps much; but in summer he is almost entirely silent, and during this season he casts his hair. Like the wolf, he allows himself to be killed with a bludgeon without

## F O X

complaining, and he always defends himself to the last with the utmost bravery: his bite is dangerous, and the severest blows will not induce him to quit his hold; he fights in silence until torn to pieces, nor has he scarcely ever been known to cry out when seized by the hounds.

The following instance is a striking proof of the fox's instinctive sagacity: The old Duke of Grafton, who had his hounds at Croydon, occasionally had foxes taken in Whittlebury forest, and sent up in the venison cart to London, for the purpose of being turned down the next morning before the hounds. In the course of these proceedings, a fox was taken from a particular coppice in the forest, and forwarded in the usual manner. The fox made his escape when hunted, and, some time after, a fox was caught in the identical coppice, the appearance of which was so strikingly like the one obtained a little time before in the same place, that the keeper entertained a strong suspicion it was the fox which had before fallen into his hands. The fox was again sent to Croydon, again hunted and again escaped. Some time after, a fox was taken in the same coppice, which those engaged in the business were well assured they had captured twice before. Under these circumstances, he had one ear slit, and some holes punched through the other, in order thus to place the matter beyond dispute should the fox again make his way back. Thus distinguished, he was again despatched to the hunting ground, and again eluded the hounds; and in the course of a few weeks was retaken in the same place. After having thus beaten his pursuers three times, and regained as often his old and favourite asylum, he ought to have been spared; but he was turned down a fourth time; and, after a very severe chase, was killed.

In 1793, a fox in the neighbourhood of Imber, Wilts, being hard run, took shelter under the covering of a well, and by the endeavours used to extricate him thence, was precipitated to the bottom, a depth of one hundred feet: the basket was let down; he laid hold of it, and was drawn up some way, when he again fell; the bucket being let down a second time, he was drawn up safe; after which he was turned off, and beat the hounds.

Dr. Goldsmith asserts, that a bitch fox, which it appears had but one cub, was unkennelled by the hounds, near Chelmsford, in Essex, when the animal, braving every danger, took the cub in her mouth and ran with it for some miles. At length being driven through a farm-yard, she was attacked by a mastiff, and obliged to drop her cub, which was taken up by the farmer. She, however, beat her pursuers, and got clear off.

In the year 1785, the hounds of Mr. B. Dudley frequently had a good drag on the banks of the Crouch river in Essex, but without finding their fox. As, however, they were one morning drawing the remote church-yard of Crickseth, which was overgrown with thick bushes, a labouring man informed the huntsman that he was too late, as renard had crept off when he heard the hounds challenge about a quarter of an hour ago. In consequence of this information the

## F O X

hounds chopped in different spots for several miles; but a fall of sleet prevented their reaching the fox that day. A week or two afterwards he was found in an adjoining copse, and after a lingering run of upwards of two hours he shaped his course to the churchyard in question. The hounds reached the place and came to a check; upon which a bitch, named Gaylass, raised herself against an old buttress of the church, and gave tongue. The master of the hounds dismounted, and, with another of the gentlemen, ascended the buttress up to the roof of the church, which was very low, and thickly covered with ivy, amongst which they found several fresh kennels. Some of the sportsmen below lifted several of the hounds upon the roof, where they were instantly in full cry, and where the fox was immediately killed.

The late Mr. Selby had a tame fox that used to run with his fox hounds; and this circumstance had not the effect of preventing the dogs from pursuing their chase in the fields, in which, it would appear, the tame fox eagerly joined.

In 1805, Mr. Salter, of Rickmansworth, Herts, had a fox that lay constantly in the kennel with his harriers; he was completely master of the feeding-yard, not suffering a hound to eat near him until he was satisfied himself.

In the year 1813, a curious exhibition took place in the Hundred House Meadow, Witley:—five wild rabbits were singly turned down, at an assigned distance, before a dog-fox, trained by Mr. C. Tearne, of Stockton, Worcestershire; and, after an excellent course, were severally killed by renard in very capital style.

At the Golden Bear, Reading, some years ago, a young fox had been placed in a wheel, and taught to turn the jack. After some time, he escaped and regained his native woods. Here he met the fate common to his species; he was pursued by the hounds, and, in his flight, ran through the town of Reading, and, springing over the half-door of the kitchen, jumped into the wheel and resumed his old occupation, in the very place where he had formerly been brought up, and thus saved his life.

We shall conclude the present article with a short, but interesting, account of the Arctic fox, which exhibits the manners of this animal, where it is but little acquainted with human nature, or the power of civilized man.—The arctic fox, as we have already observed, is only to be met with in the frozen regions of the north, but they exist in incredible numbers in the islands of the frozen ocean; and Steller has given us the following ample and interesting description of their manners.

“During my unfortunate abode (says he) on Behring’s Island, I had but too many opportunities of studying the nature of these animals; which far exceed the common fox in impudence, cunning, and roguery. The narrative of the innumerable tricks they played us might vie with Albertus Julius’s history of the Apes on the Island of Saxonburgh. They forced themselves into our habitations by night as well as by day, stealing all that they could carry off—even things

that were of no use to them, as knives, sticks, and clothes. They were so extremely ingenious as to roll down our casks of provisions, several *poods* (the pood is equal to forty Russian pounds, each of which is something less than the English pound) in weight; and then steal the meat out with such skill, that, at first, we could not bring ourselves to ascribe the theft to them. While employed in stripping an animal of its skin, it has often happened that we could not avoid stabbing two or three foxes, from their rapacity in tearing the flesh out of our hands. If we buried it ever so carefully, and even added stones to the weight of the earth that was upon it, they not only found it out, but with their shoulders pushed away the stones, by lying under them, and in this manner helping one another. If, in order to secure it, we put any animal on the top of a high post in the air, they either dug up the earth at the bottom, and thus tumbled the whole down; or, one of them climbed up, and, with incredible artifice and dexterity, threw down what was upon it.

“ They watched all our motions and accompanied us in whatever we were about to do. If the sea threw up an animal of any kind, they devoured it before we could arrive to rescue it from them; and if they could not consume the whole of it at once, they trailed it in portions to the mountains, where they buried it under stones before our eyes, running to and fro as long as any thing remained to be conveyed away. While this was doing, others stood on guard and watched us. If they saw any one coming at a distance, the whole troop would combine at once and begin digging altogether in the sand till even a sea bear in their possession would be so completely buried under the surface that not a trace of it could be seen. In the night time, when we slept in the fields, they came and pulled off our night-caps, and stole our gloves from under our heads, with the beaver coverings and the skins that we lay upon. In consequence of this, we always slept with our clubs in our hands, that, if they awoke us, we might drive them away or knock them down.

“ When we made a halt to rest by the way, they gathered round us, and played a thousand tricks in our view; and when we sat still they approached us so near that they gnawed the thongs of our shoes. If we lay down as if intending to sleep, they came and smelt at our noses to find whether we were dead or alive. On our first arrival, they bit off the nose, fingers, and toes of our dead, while we were preparing the grave; and thronged in such a manner about the infirm and sick that it was with the greatest difficulty we could keep them off.

“ Every morning we saw these audacious animals prowling about among the sea lions and sea bears lying on the strand; smelling at such as were asleep to discover if some of them might not be dead; if that happened to be the case, they proceeded to dissect him immediately, and soon afterwards all were at work in dragging the parts away. Because the sea lions in their sleep over-lay their young, the foxes every morning examined the whole herd of them, one by one, as if conscious of this circumstance; and immediately dragged away the dead cubs from their dams.

“As they would not suffer us to be at rest neither night nor day, we became so exasperated against them, that we killed them, young and old, and harassed them by every means we could devise. When we awoke in the morning there always lay two or three that had been knocked on the head the preceding night; and I can safely affirm, that, during my stay upon the island, I killed above two hundred of these animals with my own hands. On the third day after my arrival, I knocked down with a club, within the space of three hours, upwards of seventy of them, and made a covering for my hut with their skins. They were so ravenous, that with one hand we could hold to them a piece of flesh, and with a stick or axe in the other could knock them down.”

FOX HUNTING, is the most impassioned, the most maddening, of all the diversions of the field. It is a rapturous gratification to which every effort of the pen becomes inadequate in its attempts at description—it must be seen to be perfectly understood—it must be felt to be enjoyed. The inhabitants of these islands are the best sportsmen in the world, and have long been in possession of the best hounds also. The opinion which foreigners entertain of the English, in regard to their proficiency in the sports of the field may be gathered from the following: In writing to his friend, Beckford observes—“You may remember perhaps when we were hunting together at Turin, and the hounds had lost the stag, and the *piqueurs* (still more in fault than they) knew not which way to try, the king bid them ask *Milord Anglois*;—nor is it to be wondered at that an Englishman should be thought to understand the art of hunting, when the hounds this country produces are universally allowed to be the best in the whole world.”

The chase of the fox, however, like many other sciences, has been in a state of progressive improvement for many years. An author, who wrote in the time of William III. in comparing the pursuit of the stag, the fox, and the hare, observes, “The stag, I confess, is a noble prize; and as the taking it requires a large pack of dogs, the very best horses, and a great expense, to the nobility and men of noble state, I have long since resigned it. The pursuit after the fox is also violent, and rather fit for those youthful heroes who glory in breaking the hearts of their horses, and venturing their own necks. The flight of these two animals is swift, and (though they make some few heads and turnings) most commonly in straight lines towards a place of refuge at some distance; the scent they

leave is generally so high, that the pack (though ever so well matched) is forced to follow after two or three strong winded leaders in a straggling yelping string; and the horsemen are cast though ever so well mounted: by this means, the music is broken, the art of the huntsman of little use, and the pleasure of those who designed to be spectators, dwindles into inquiries *which way the dogs went?* However, as these games afford an opportunity to our generous youth, to shew their courage, to boast of the performance of themselves and their horses, and to excel one another in feats of activity; as the preservation of lambs or geese is an act of charity to the honest farmer; and as a venison pasty is a savoury ornament to my lady’s table, I would by no means deprecate the triumphs obtained by our gallant Nimrods in the conquest of such beasts.

“Yet I hope for pardon from my more sprightly brethren, if I give my vote for the innocent hare above all other game. The transports of every mortal breast at the sight of that little quadruped is no less amazing than unaccountable, and has often made me inclined to imagine she has some hidden, mechanical, attractive power over man as well as beast: whatever it be, it ought to be a constant motive of gratitude to the indulgent Creator, that has furnished us with this physis, so delicious to the taste, as well as salutary in effect. Let the philosopher, the grave Stoic himself, be present at the tracing and unravelling the morning walk, and see this subtle absconding creature suddenly starting in view of the whole cry, and he shall feel a passion that all his affected apathy cannot cover. Let the most morose and incredulous sceptic suffer himself to be persuaded to ride the chase, or but to stand on an eminence and observe the perplexing shifts and wiles of

the flyer and pursuers, and he must be convinced that God's providence is over all his works, that the minutest and vilest parts of the creation have been the care and contrivance of his infinite wisdom ! The swiftness and subtlety of this incomparable creature demonstrate that she was made to give us pleasure, with purpose to tempt us into the wholesome fields. The doublings and indentures she is perpetually making argues a design in their great Creator that every hound should come in to bear a part of the chorus, that each should have an opportunity of shewing his acuteness and policy in the pursuit; and the tours and rings that she naturally traverses and repeats over the same ground, gives an advantage to every one of the company to enjoy their share, even old men and maidens.

"The chase after the fox or stag is violent, and little more than riding and running; but the hare displays the very art of hunting; she affords a pleasure worthy of a philosopher, a curiosity that may justly raise the admiration of the wisest statesman, physician, or divine. Let the most learned and inquisitive naturalist dissect the carcase of this feeble animal, let him carefully trace every sinew and muscle, let him note the smallness of her head and neck, the fulness and prominency of her eyes, the leanness of her shoulders, the depth of her chest, the largeness of her heart and lungs, the strength of her joints, the hardness of her little bones, the firm braces of her back, the slenderness of her belly, the portable shape of her paps or udders, the measure of her ears, the firmness of her gaskins, the superior length of her hinder legs, the obscurity of her colour, and the inimitable contexture of her feet; and let him then declare the causes and ends of this wonderful formation; let them dare to say she could have been formed better in any one part to qualify her for lying hid in her form, for nimbleness of flight, for holding out against her foes, or for giving pleasure to man."

Such are the notions of a sportsman of the old school, of one who never witnessed fox hunting in perfection, who was passionately attached to the pursuit of the hare, whose opinion will have very little influence at the present day, at least as far as relates to the chase of the fox. In the time of Beckford fox hunting had very much improved, and his opinion of the comparative merits of the chase of the fox and the pursuit of the hare may be very

clearly ascertained from various observations scattered through his work:—in one place, he remarks, that hare hunting is very well as a gallop before dinner; in another, that the mere finding of a fox is superior to the best run with a hare; and his comparative remarks on hunting still further elucidate the subject, or, at least, place in a clearer point of view his particular notions upon it:—"Fox hunting, an acquaintance of mine says, is followed because you can ride hard, and do less harm in that than any other hunting. There may be some truth in the observation (continues Beckford); but to such as love the riding part only of hunting, would not a trail scent be much more suitable? Gentlemen, who hunt for the sake of a ride, who are indifferent about the hounds, and know little of the business, if they do no harm, it is to the full as much as we have reason to expect from them; whilst those of a contrary description, do good, and have much greater pleasure. Such as are acquainted with the hounds, and can at times assist them, find the sport more interesting, and frequently have the satisfaction to think, that they themselves contribute to the success of the day. This is a pleasure you often enjoy; a pleasure without any regret attending it. I know not what effect it may have on you; but I know that my spirits are always good after good sport in hunting; nor is the rest of the day ever disagreeable to me afterwards. What are other sports compared with this, which is full of enthusiasm! Fishing is, in my opinion, a dull diversion; shooting, though it admits of a companion, does not allow of many: both, therefore, may be considered as selfish and solitary amusements compared with hunting; to which, as many as please are welcome. The one might teach patience to a philosopher; and the other, though it might occasion great fatigue to the body, seldom affords much occupation to the mind. Whereas, fox hunting is a kind of warfare—its uncertainties, its fatigues, its difficulties, and its dangers, rendering it interesting above all other diversions."

Notwithstanding the observations made above, that fox hunting has much improved since the time of Beckford; yet his "Letters" may be regarded as the text book of the chase, or as the sterling principles of fox hunting.—He says "I shall not pretend to lay down rules which are to be equally good in every country; I shall think myself sufficiently justified

in recommending such as have been tried with success in the countries where I have generally hunted. I need not, I think, advise you not to adopt too easily the opinions of other men. You will hear a tall man say it is nonsense to ride any but large horses; and every little man in company will immediately sell his little horses, buy such as he can hardly mount, and ride them in hilly countries, for which they are totally unfit. Pride induces some men to dictate; indolence makes others like to be dictated to; so both find their account in it."

On the subject of the kennel, Beckford remarks, that "it is not only the first thing you should do (that is, building a kennel), but it is also the most important. As often as your mind may alter, so often may you easily change from one kind of hound to another; but your kennel will still remain the same;" and therefore it is highly advisable that it should be planned and built in a proper manner. It is true,

"Upon some little eminence erect,  
And fronting to the ruddy dawn; its courts,  
On either hand, wide op'ning to receive  
The sun's all cheering beams, when mild he shines,  
And gilds the mountain tops."

Such as Somerville directs may be the situation; its size must be suited to the number of its inhabitants. Neatness should be its characteristic without, and cleanliness within. There are some objections to the kennel being near the house:—"I foresee still more (says Beckford) to its being at a distance: there is a vulgar saying, that it is the master's eye that makes the horse fat; I can assure you it is even more necessary in the kennel, where cleanliness is not less essential than food."

Two kennels seem absolutely necessary to the well-being of the hounds; when there is but one it is seldom sweet; and, when cleaned out, particularly in winter, the hounds suffer both whilst it is cleaning, and as long as it remains wet afterwards. One of these, for the sake of clearness and perspicuity, may be called the *hunting kennel*, or that kennel into which the hounds are drafted that are to hunt the next day. Used always to the same kennel, the hounds will be drafted with little trouble; they will answer to their names more readily, and you may count your hounds into the kennel with as much ease as a shepherd counts his sheep out of the fold.

hounds may be kept in barns and stables' "but those who keep them in such places can best inform you whether their hounds are capable of answering the purpose for which they are kept." The sense of smelling in a hound is so exquisite that every stench must be hurtful to it: it is that faculty on which the hopes of the sportsman depend; it is that which must lead him over greasy fallows, where the feet of the game pursued, being clogged, leave little scent behind, as well as over stony roads, through watery meads, and where sheep have stained the ground.

Cleanliness, therefore, is as indispensable to the nose of a hound as it is essential to his health. Dogs are naturally cleanly animals: they seldom, when they can help it, dung where they lie: air and fresh straw are necessary to keep them healthy. Poverty and filthiness will produce that loathsome disease, the mange. The kennel therefore should be the particular care of the sportsman:—

#### SOMERVILE.

When the feeder first comes to the kennel in the morning, he should let out the hounds into the outer court, at the same time opening the door of the hunting kennel, lest want of rest, or bad weather, should incline them to go into it. The lodging-room should then be cleaned out, the doors and windows of it opened, the litter shaken up, and that whole kennel made sweet and clean before the hounds return to it again. The great court and other kennels are not less to be attended to, nor should any omission, hurtful to the hounds, be passed over in silence.

The floor of each lodging-room should be flagged (that is, paved with large stones) and sloped on each side to run to the centre, with a gutter to carry off the water, that, when they are washed, they may soon be dry. If water should stand, through any fault in the floor, it should be carefully mopped up; for, as warmth is in the greatest degree necessary to hounds after work, so damps are equally prejudicial. So convinced was Beckford of the necessity of uncommon attention in the kennel, that, in writing to his friend, he thus expresses himself:—"You will think me perhaps too particular in these directions; yet there can be no harm in

your knowing what your servants ought to do; as it is not impossible but that it may be sometimes necessary for you to see that it is done. In your military profession, you are perfectly acquainted with the duties of a common soldier, and though you have no further business with the minutiae of it, there is no doubt but you still find the knowledge of them useful to you: believe me, they may be useful here; and you will pardon me, I hope, if I wish to see you a Martinet in the kennel, as well as in the field. Orders given without skill are seldom well obeyed, and where the master is either ignorant, or inattentive, the servant will be idle."

The kennel should have three doors, two in the front and one in the back; the last to have a lattice window in it, with a wooden shutter, which is constantly to be closed when the hounds are in, except in summer, when it should be left open all the day. This door answers two very necessary purposes: it gives an opportunity of carrying out the straw, when the lodging-room is cleaned, and as it is opposite to the window, will be a means to let in a thorough current of air, which will greatly contribute to the keeping of it sweet and wholesome. The other doors will be of use in drying the room, when the hounds are out; and, as one is to be kept shut, and the other hooked back (allowing just room for a dog to pass) they are not liable to any objection. The great window in the centre should have a folding shutter; half or the whole of which may be shut at nights, according to the weather; and the kennel, by these means, may be kept warm or cool, just as you please to have them. Beckford, in speaking of his own kennel, says, "The two great lodging-rooms are exactly alike; and as each has a court belonging to it, are distinct kennels, and are at the opposite ends of the building; in the centre of which is the boiling-house and feeding-yard; and on each side a lesser kennel, either for hounds that are drafted off, hounds that are lame or sick, or for any other purposes, as occasion may require. At the back of which, as they are but half the depth of the two great kennels, are places for coals, &c. for the use of the kennel. There is also a small building in the rear for hot bitches. The floors of the inner courts, like to those of the lodging-rooms, are bricked and sloped to run to the centre, and a channel of water, brought in by a leaden pipe, runs through the middle of them. In the centre of each

court is a well, large enough to dip a bucket to clean the kennels; this must be faced with stone, or it will be often out of repair. In the feeding yard, you must have a wooden cover."

The benches should have holes or interstices to let the urine through, with hinges and hooks in the wall, that they may fold up for the greater convenience of washing out the kennel; and they should be made as low as possible, that a tired hound may have no difficulty in jumping up. The boiler should be cast-iron.

Beckford continues, and, speaking of his own kennel, says—"the rest of the kennel consists of a large court in front, which is also bricked, having a grass court adjoining, and a little brook running through the middle of it. The earth, which was taken out of it, is thrown up into a mount, where the hounds in summer delight to sit. This court is planted round with trees, and has besides a lime tree, and some horse chesnut trees near the middle of it, for the sake of shade. A high pale incloses the whole, part of which to the height of about four feet is close; the other open; the interstices are about two inches wide. The grass court is pitched near the pales to prevent the hounds from scratching out.—If you cannot guess the intention of the posts you see in the courts, there is scarcely an inn window on any road, where the following lines will not let you into the secret:—

'So dogs will p— where dogs have p—'d before.'

This is done to save the trees, to which the urinary salts are prejudicial. If they are at first backward in coming to them, bind some straw round the bottom, and rub it with galbanum. The brook in the grass court may serve as a stew; your fish will be very safe.

At the back of the kennel is a house, thatched and furzed up at the sides, big enough to contain at least a load of straw. Here should be a pit ready to receive the dung, and a gallows for the flesh. The gallows should have a thatched roof, and a circular board at the posts of it to prevent vermin from climbing up.

A stove, I believe, is made use of in some kennels; but where the feeder is a good one, a mop properly used will render it unnecessary. I have a little rick of hay in the grass yard, which I think is of use to keep the hounds clear and fine in their coats, you will find them frequently rubbing themselves against it:

the shade of it also is useful to them in summer. If ticks at any time should be troublesome in your kennel, let the walls of it be well washed: if that does not destroy them, the walls should then be whitewashed.

In the summer, when you do not hunt, one kennel will be sufficient; the other then may be for the young hounds, who should also have the grass court adjoining it. It is best at that time of the year to keep them separate, and it prevents many accidents which otherwise might happen; nor should they be put together till the hunting season begins. If your hounds are very quarrelsome, the feeder may sleep in a cot in the kennel adjoining; and if they are well chastised at the first quarrel, his voice will be sufficient to settle all their differences afterwards.

My kennel is close to the road side, but it was unavoidable. This is the reason why my front pale is close, and only the side ones open; it is a great fault; avoid it if you can, and your hounds will be the quieter.

Upon looking over my letter, I find I begun with Mr. Somervile, recommending a high situation for the kennel, and afterwards talk of a brook running through the middle of it; I am afraid you will not be able to unite these two advantages; in which case, there is no doubt but water should be preferred. The mount I have mentioned will answer all the purposes of an eminence. Besides, there should be moveable stages on wheels for the hounds to lie upon, at any rate, however, let your soil be a dry one."

Beckford's establishment consisted of

about forty couple of hunting hounds, his kennel was made for the requisite accommodation, and beyond a doubt well planned for the purpose. A similar plan, upon an enlarged scale, would, of course, answer for a more extensive establishment; and most of the modern fox kennels contain more than the number of hunting hounds above mentioned. Those, however, who contemplate building a kennel for hounds, would do well to visit several of the more celebrated establishments, as well as any others which may fall in their way, as it seldom happens but each contains some little improvement; and thus all that was desirable might be united.

In regard to the tenants of the kennel, the hounds, various opinions will be formed. Beckford says he prefers hounds of the middle size; and says, that all middle sized animals are strongest and best able to endure fatigue. In height, as well as the colour of hounds, most sportsmen have their prejudices; but, in their shape, there cannot be much diversity of opinion. Some sportsmen boldly affirm, that a small hound will oftentimes beat a large one; that he will climb hills better, and go through cover quicker; whilst others, are not less ready to assert, that a large hound will make his way in any country, will get better through the dirt than a small one; and that no fence, however high, can stop him. There is a certain size best adapted for business, which is that between the two extremes, and such hounds will not suffer themselves to be disgraced in any country. That acute observer, Somervile, thus clearly expresses it:—

---

“ But here a mean  
Observe, nor the large hound prefer, of size  
Gigantic; he, in the thick-woven covert,  
Painfully tugs, or in the thorny brake,  
Torn and embarrass'd, bleeds. But, if too small,  
The pigmy brood in every furrow swims;  
Moil'd in the clogging clay, panting they lag  
Behind inglorious; or else, shivering, creep,  
Benumb'd and faint, beneath the sheltering thorn.  
For hounds of middle size, active and strong,  
Will better answer all thy various ends,  
And crown thy pleasing labours with success.”

As far as relates to appearances, to look well, they should be nearly all of a size, and seem as if they belonged to the same family. If handsome withal, they are then perfect.

There are essential points in the shape of a hound which ought always to be at-

tended to by a sportsman; for if he is not of a perfect symmetry, he will neither run fast, nor bear much work: he has much to undergo, and should have strength proportioned to it. His legs should have the true and peculiar straightness of nature; his feet should be round and small,

his toes bony and narrow, his chest deep, and back broad ; his head (contrary to the generally received opinion) should be *large*. Such young hounds as are out at the elbows, and such as are weak from the

knee to the foot, should never be taken into the pack.

Somerville thus describes what he considers as a perfect hound :—

————— “ See there with count'nance blythe,  
And with a courtly grin, the fawning hound  
Salutes thee cow'ring ; his wide op'ning nose  
Upwards he curls, and his large sloe-black eyes  
Melt in soft blandishments and humble joy ;  
His glossy skin, or yellow, pied, or blue,  
In lights or shades, by nature's pencil drawn,  
Reflects the various tints ; his ears and legs,  
Fleckt here and there, in gay enamell'd pride,  
Rival the speckled pard ; his rush-grown tail  
O'er his broad back bends in an ample arch ;  
On shoulders clean, upright and firm he stands ;  
His round cat foot, straight hams, and wide-spread thighs,  
And his low-dropping chest, confess his speed,  
His strength, his wind, or on the steepy hill,  
Or far extended plain ; in every part  
So well proportioned, that the nicer skill  
Of Phidias himself can't blame thy choice.  
Of such compose thy pack.” —————

Somerville says nothing of the head of the hound, which is, after all, the most important consideration.

The author of an *Essay on Hunting*, published, as before observed, about the reign of William III. and which has been since several times reprinted, on the subject of hounds makes the following observations :—“ The most satisfactory reply to every hunter is, that his own kind is the best. But such as are setting up a new cry, I would advise to begin to breed on the middle sized dogs, between the southern hound and the northern beagle. 'Tis true, the finest and most curious sport is generally with the former. Whether it be the particular formation of their long trunks, or the extraordinary moisture that always cleaves to the nose and lips of this sort of dogs, I need not inquire in this place ; but certain it is, that they are endued with the most accurate sense of smelling, and can often take and distinguish the scent an hour after the lighter beagles can make nothing of it. Their slowness also better disposes them to receive the commands and directions of the huntsman ; and their much phlegm (for there seems to be a difference in the constitution of other animals as well as man) ; I say, their phlegm gives them patience to proceed with caution and regularity, to make sure of every step as they go, carefully to describe every indenture, to unravel each puzzling trick of figure. But

these grave sort of dogs are fittest for masters of the same temper. As they are able to hunt a cold scent, they are more apt to make it so, by their want of speed and vigour to push forward and keep it warm ; their exactness often renders them trifling and tedious ; and like some nice dames, who stand picking out every dust and mote, whilst they might dress the meat. By this means, though the hunt be finer, yet the prey (which is by some thought necessary to complete the sport) very often escapes ; the length of the chase takes up the time, and exposes them to numerous hazards of losing.”

The sportsmen of the old school had no clear or well defined ideas in regard to the olfactory organs of the dog. The cause of the comparative powers of the animal under consideration was never investigated, and as it became the fashion to regard a small head as beautiful in the hound, exertions were made to produce them in this way, and thus thousands of worthless animals were seen, which were blamed for their inferiority of a faculty, which the thoughtless breeders had rendered them incapable of receiving in greater perfection. No dog can possess a good nose, or an exquisite sense of smell, which has not a large head. This we will prove anon. Beckford, who has written so well and so judiciously on hunting, was equally in the dark on this subject :—In writing to his friend, he says “ I find that I have

mentioned a small head as one of the necessary points about a hound: you will please to understand it as relative to *beauty only*; for as to *goodness*, I believe large headed hounds are no way inferior. Men are apt to be prejudiced by the sort of hounds they themselves have been most accustomed to. Those who have been used to the sharp-nosed fox hound will hardly allow a large-headed dog to *be* a fox hound; yet both equally are fox hounds—speed and beauty are the chief excellencies of the one, whilst stoutness and tenderness of nose in hunting, are characteristic of the other. I could tell you that I have seen very good sport with very unhandsome packs, consisting of hounds of various sizes, differing from one another as much in shape and look, as in their colour; nor could I trace the least sign of consanguinity amongst them.”

The author of the *Shooter's Companion* (Johnson) was the first to explain and elucidate the olfactory organs of the dog, and to give a satisfactory reason why one dog could smell so much better than another. Johnson observes, “It is very well known that the sense of smell varies very much in dogs; or, to speak as a sportsman, some of them possess better noses than others. In dogs with broad heads, the *os æthmoides*, or sive bone, is much larger than in narrow headed dogs; the *laminæ cribrose*, or the sive itself, is therefore more capacious and contains more openings; so that the olfactory nerves, which pass through it, are more numerous, and are divided more minutely, and thus that exquisite acuteness of smell is produced, which is found to obtain in the old English blood-hound, and all dogs with broad heads; this excellence or superiority of the olfactory organs, is further assisted by the largeness and flexibility of the lips and skin about the nose, which thus admit of a much greater extension of the olfactory nerves, and render them susceptible of external impressions. The olfactory nerves resemble a bunch of small white cords, one end of which is connected with the brain, while the other, descending the head, spreads into numerous ramifications, reaching to the edges of the lips, as well as to the extremity of the nose.

Hence the inferiority of the greyhound's sense of smell will be easily perceived: his head is narrow, while his lips are thin and compressed; and in consequence of this inflexibility, and the con-

tracted structure of the head, that breadth and extension of nerve are inadmissible; and, to make up, as it might seem, for this defect, nature has endued him with a celerity, which is not to be met with in any other species of the dog.

“All dogs, therefore, with broad heads must possess superior organs of smell: but it does not appear that a narrow or sharp nose presents any obstacle, as the main bulk of the olfactory nerves is situated in the head; but I think it is abundantly evident that a very long nose (like the greyhound) must always be detrimental, since the impression of scent, externally caught, must have farther to travel to the brain. The wolf and the fox appear to have sharp noses; but their heads are remarkably broad and capacious;” and even their noses will be found, upon a close inspection, to be extremely flexible; or, in other words, they have a considerable portion of very flexible upper lip, which is no doubt well calculated to receive the external impression of scent; and their olfactory organs, are unquestionably exquisite. Experience in fact fully verifies these conjectures: the dogs most remarkable for exquisite sense of smell are equally distinguished for broad heads; and the gradations are easily to be traced: the talbot, the original of all our modern hounds, exhibits the outward characteristics of superior olfactory nerves in a very obvious and striking manner: by crossing the talbot with something of the greyhound breed, the stag-hound was produced:—the speed of the talbot was thus increased; but as the head became more compressed, the sense of smell suffered accordingly. The fox-hound is a still further remove, and his olfactory organs are inferior to those of the stag-hound; and the reason in fact why well-bred stag-hounds distinguish the blown or hunted deer from the herd, is entirely owing to their proximity to the talbot; while the fox-hound, by being further removed, is unable to distinguish the hunted or blown fox, when another fox happens to come in the way during the chase.

“I have frequently thought (continues the author of the *Shooter's Companion*,) that the size of the ears is in some degree a criterion of the sense of smell. The talbot has amazing large ears; the stag-hound's are smaller; the fox-hound's the smallest of the three.” It is surprising to see how truly the ears of a hound mark his degree, as it were, or the distance he is removed

from the original talbot; the very first cross from this dog elevates the ears, in some degree, at the roots, and they are altogether smaller; they thus continue progressively, according as the animal becomes removed from the original stock.

Also, the voice, as far as relates to hounds (pointers and setters inclusively, as they are evidently of the hound tribe); is another remarkable characteristic. The talbot has the deepest and most powerful voice of any dog; the progressions are obvious.

"The pointer is remarkable for a broad, capacious head, as well as for large pendant ears; and those setters distinguished for the goodness of their olfactory powers, will be found to possess a very considerable expansion of the head, though their noses may taper more than the nose of the pointer. Thus, at first glance, a bull dog will be supposed to excel in this respect; but, on examination, it will be found that his head is rather chubby than broad, while the skin about the mouth is comparatively inflexible and compressed, his under jaw projected, and his nostrils thrown so far back as to prevent that immediate contact with external objects, which is seen to obtain in the dogs before mentioned; yet, notwithstanding all these objections, the bull dog's sense of smell is of a superior order, which arises no doubt from the capaciousness of his head.

"The sense of smell, like most other faculties, is improved by practice. Dogs which are kept in towns, and but little exercised, will always be found inferior to such as are quartered in the country."

Recurring again to Beckford, we repeat: "I have seen very good sport with very unhandsome packs, consisting of hounds of various sizes, differing from one another as much in shape and look, as in their colour; nor could I trace the least sign of consanguinity amongst them: considered separately the hounds were good; as a pack, they were not to be commended; nor could you be satisfied with any thing so incomplete. You will find nothing so essential to your sport as that your hounds run well together; nor can this end be better attained than by keeping them, as near as you can, of the same sort, size, and shape."

Perhaps the greatest excellence of a pack of fox-hounds is the head they carry; and that pack may be said to go the fastest that can run ten miles in the shortest period, notwithstanding the hounds separately may not run so fast as many

others. A pack of hounds, considered in a collective body, go fast in proportion to the excellence of their noses and the head they carry:—hence a perfect fox-hound should be equally remarkable for speed, for exquisite sense of smell, and also for the most persevering spirit and capability of endurance. To unite such qualifications there are certain indispensable requisites, such as a body and legs formed for strength and motion, a capacious head, &c.

The following extract of a letter of Will Deane, Earl Fitzwilliam's huntsman, is strikingly illustrative of the remarks just made on the subject of the hound's head:—amongst other observations, Deane remarked, that "he could not guess at Lord Foley's dislike of Glider (Glider was one of a draft of young hounds) then sent, which was of the best blood in the country, being got by Mr. Meynell's Glider out of Lord Fitzwilliam's Blossom, and was moreover the most promising young hound he had ever entered, unless his Lordship took a distaste to the *largeness of his head*; but he begged leave to assert, that although it might appear a little out of size, there was a world of mischief to the foxes contained in it." The event justified Deane's prediction in the utmost latitude, for Glider was a most capital dog, and long a favourite stallion hound, notwithstanding the magnitude of his head; which, by the bye, was the very fountain whence his superior excellence sprung.

In consequence of the rage, which for many years existed, for what was considered beauty in fox-hounds, these dogs were frequently bred in such a manner that they were not able to hunt at all; and it is very doubtful whether most of the modern fox-hounds are not bred with heads too small to contain the requisite quantity of olfactory nerves. We have stated above the qualities necessary to constitute the perfect fox-hound; and though speed must always be deemed an indispensable qualification, yet it is doubtful whether dogs a shade slower than the present very high bred fox-hounds, but with superior noses, would not get over the ground faster, or at least finish the run, in general, in a shorter period, as from their superior olfactory organs, they would be much less liable to checks. The uncommon speed of the modern fox-hound enables him to keep very near the fox, if the scent be good, and of course to kill him in high style; but it frequently

happens, and indeed must frequently so happen, that the narrow headed hounds are not able to hunt, owing to the unfavourable state of the atmosphere (see the article SCENT). Surely it is not impossible to unite the speed of the modern fox-hound to more exquisite sense of smell, or better nose.

“Some hounds (says the author from which we have repeatedly quoted) that I have seen would creep all through the same hole, though they might have leapt the hedge, and would follow one another in a string as true as a team of cart-horses.—I had rather see them like the horses of the sun—*all abreast*.

A friend of mine killed thirty-seven brace of foxes in one season: twenty-nine of the foxes were killed without any intermission. I must tell you at the same time that they were killed by hounds bred from a pack of harriers; nor had they I believe a single skirter belonging to them. There is a pack now in my neighbourhood, of all sorts and sizes, which seldom miss a fox; when they run, there is a long string of them, and every fault is hit off by an old southern hound. However, out of the last eighteen foxes they hunted, they killed seventeen; and I have no doubt but as they become more complete more foxes will escape them. Packs which are composed of hounds of various kinds seldom run well together, nor do their tongues harmonize, yet they generally, I think, kill most foxes; but I must confess, that, unless I like their style of killing them, whatever may be their success, I cannot be completely satisfied. I once asked the famous Will. Crane how his hounds behaved—‘very well, Sir, (he replied) they never come to a fault but they spread like a sky-rocket.’ Thus it should always be.

A famous sportsman asked a gentleman what he thought of his hounds—‘Your pack is composed, Sir, (said he) of dogs which any other man would *hang*; they are all skilters.’ This was taken as a compliment. However, do not think I recommend it to you as such; for though I am a great advocate for style, in the killing of a fox, yet I never forgive a professed skirter: where game is in plenty, they are always changing, and are the loss of more foxes than they kill.”

The number of hounds to be kept must depend on circumstances, such as the nature of the country, how often it is intended to hunt, &c. The taking out too many hounds is a useless incumbrance; though it is not so material what your number is, as it is that all your hounds should be steady, and as nearly as possible of equal speed. About twenty couple would seem a medium or proper number—when a great number of hounds are taken out, they are very apt to divide, particularly in extensive covers. With forty couple of hunting hounds the sportsman may hunt three times a week; and, by thus keeping them in good exercise, will kill more foxes than if a greater number were kept, unless they went out oftener. Hounds that remain for any time without work always get out of wind, and become oftentimes riotous. The old and lame, such as are low in flesh, and such as you are sure idleness cannot spoil, are those which should be left at home.

Too many old hounds should not be kept.—If the hounds are to run well together none should be kept longer than five or six seasons; though there is no saying with certainty what number of seasons a hound will last.

A good feeder is an essential part of a fox hunting establishment.—He should be active, good tempered (for the sake of the animals entrusted to his care) and one who will punctually attend to any orders that may be given him. The whole should be under the eye of the master, as already observed; and he who allows a huntsman to manage his hounds as he pleases, without controul, literally keeps them for *his* amusement. Servants may be permitted to remonstrate, but they should never be suffered to disobey.

The keeping of the kennel sweet and clean cannot be too much impressed on the mind of the feeder; and if he sees the master exact, he will be so himself. The boiling for the hounds, mixing of the meat, and getting it ready for them at proper hours, is what the huntsman ought to superintend, or at least see that it is properly done. Dogs should not have their meat too hot; and it should be mixed up as thick as possible.

In speaking on this subject, Somerville thus expresses himself:—

“O’er all let cleanliness preside; no scraps  
Bestrew the pavement, and no half-pick’d bones,  
To kindle fierce debate, or to disgust  
That nicer sense, on which the sportman’s hope

And all his future triumphs must depend.  
 Soon as the prowling pack, with eager joy,  
 Have lapp'd their smoking viands, morn and eve,  
 From the full cistern, lead the ductile streams,  
 To wash thy court, well paved, nor spare thy pains;  
 For much to health will cleanliness avail.  
 Seek'st thou for hounds to climb the rocky steep,  
 And brush th' entangled covert, whose nice scent  
 O'er greasy fallows and frequented roads  
 Can pick the dubious way? Banish far off  
 Each noisome stench; let no offensive smell  
 Invade thy wide inclosure, but admit  
 The nitrous air and purifying breeze."

The huntsman should attend the feeding of the hounds, and they should be drafted according to the condition they are in. In all packs some hounds will feed better than others; some there are that will do with less meat; and it requires a nice eye and great attention to keep them in equal flesh:—it is what distinguishes a good kennel huntsman, and is of the utmost consequence. Huntsmen are apt to feed their hounds in too great a hurry:—it is no easy task to distinguish with nicety the order a pack of hounds are in, and the different degrees of it—to be done well it requires more than an ordinary degree of circumspection.

Beckford observes, "When my huntsman feeds the hounds, he calls them all over by their names, letting in each hound as he is called: it has its use—it uses them to their names, and teaches them to be obedient. Were it not for this, I should disapprove of it entirely: since it certainly requires more coolness and deliberation to distinguish with precision which are best entitled to precedence, than this method of feeding will admit of; and unless flesh is in great plenty, those that are called in last may not have a taste of it. To prevent this inconvenience, such as are low in flesh, had better, I think, be all drafted off into a separate kennel; by this means, the hounds that require flesh will have an equal share of it. If any are much poorer than the rest, they should be fed again—such hounds cannot be fed too often. If any in the pack are too fat, they should be drafted off, and not suffered to fill themselves. The others should eat what they will of the meat."

Notwithstanding the neutralizing manner in which such an authority as Mr. Beckford speaks of the method of feeding by calling them by their names, one by one; yet, it is an admirable plan, and may be very confidently recommended

for adoption—in fact there are few establishments where it is not practised. Indeed, this gentleman sneers at that discipline of the kennel, which cannot be too highly applauded:—He observes:—"I have been told that in one kennel in particular, the hounds are under such excellent management, that they are constantly fed with the door of the feeding yard open; and the rough nature of the fox-hound is changed into so much politeness, that he waits at the door till he is invited in; and what perhaps is not less extraordinary, he comes out again, whether he has satisfied his hunger or not, the moment he is desired; the effect of severe discipline." He proceeds, "the gentleman who has carried this matter to its utmost perfection has attended to it regularly himself; has constantly acted on fixed principles, from which he has never deviated, and I believe has succeeded to the very utmost of his wishes. All hounds, more especially young ones, should be called over often in the kennel; and most huntsmen practice this lesson as they feed their hounds. They flog them while they feed them,—and if they have not always a bellyfull one way, they seldom fail to have it the other. It is not, however, my intention to oppose so general a practice, in which there may be some utility; I shall only observe that it should be used with discretion; lest the whip should fall heavily in the kennel on such as never deserve it in the field.

My hounds are generally fed about eleven o'clock; and if I am present I take the same opportunity to make my draft for the next day's hunting. I seldom, when I can help it, leave this to my huntsman; though it is necessary he should be present when the draft is made, that he may know what hounds he has out."

It is a bad custom to use hounds to the boiling-house, as it is apt to make them

nice, and may prevent them from ever eating their kennel meat. What they have should always be given them in the feeding yard, and, for the same reason, though it be flesh, it is better it should have some meal mixed with it.

If hounds are low in flesh, and have to go far to cover, they should have a little thin lap in the evening before hunting; though, generally speaking, hounds should be sharp set before hunting—they run the better for it.

If hounds, after long rest, should have become too fat, by feeding them for a day or two on thinner meat than you give the others, it will answer better than the usual method of giving them the same meat, but stinting them in the quantity of it.

Hounds should be turned into the grass court; or, where there is a convenient place, even out of the kennel for a few minutes, after feeding, to empty themselves; as it will contribute much to the cleanliness of the kennel.

Every day, when hounds come in from hunting, they should be carefully looked over, and such as have sustained any injury should be immediately attended to. If such hounds as are unable to work can be permitted to run about the house, it will be of great service to them.

The huntsman should pay particular attention to the health of the hounds; and if he is well acquainted with his business, he will generally prevent the ill-effects of disease by perceiving the incipient cause. Whenever a dog droops, and looks dull and heavy about the eyes, he should be instantly bled, which will relieve him immediately. Physic should be administered when they are costive. Recurring to Beckford, he says, "Every Thursday during the hunting season, my hounds have a pound of sulphur given them in their meat, and every Sunday throughout the year they have plenty of greens boiled up with it: I find it better to fix the days, as it is then less liable to be forgotten.—I used to give the wash from the kitchen, but I found it made them thirsty, and it is now omitted in the hunting season. A horse, fresh killed, is an excellent meal for hounds after a hard day; but they should not hunt till the third day after it. The bones broken are good food for poor hounds, as there is great proof in them. Sheep's trotters are very sweet food, and will be of service when horse flesh is not to be had. Oatmeal, I believe, makes the best meat for

hounds; barley is certainly the cheapest and on that account it is given in many kennels; but it is heating, does not mix up so well, nor is there near so much proof in it as in oatmeal. If mixed an equal quantity of each, it will then do very well. Much depends on the goodness of the meal itself, which, I believe, is not often attended to.

During the summer months, when my hounds do not hunt, they have seldom any flesh allowed them; and are kept low, contrary, I believe, to the usual practice of most kennels, whose mangy hounds in summer are but too often seen. Huntsmen sometimes content themselves with checking this disorder, when, with less trouble perhaps, they might prevent it. A regular course of whey and vegetables, during the hot months, must certainly be wholesome, and is without doubt the cause that a mangy hound is an unusual sight in my kennel. Every Monday and Thursday my hounds go for whey till the hunting season begins, are kept out several hours, and are often made to swim through rivers during the hot weather. After their last physic, and before they begin hunting, they are exercised on the turnpike road to harden their feet, which are washed with strong brine as soon as they come in. Little straw is necessary during the summer; but when they hunt, they cannot have too much, nor have it changed too often. In many kennels they don't boil for the hounds in summer, but give them meal only—in mine it is always boiled, but with this difference, that it is mixed up thin instead of thick. The physic I give is two pounds of sulphur, one pound of antimony, and a pint and a half of syrup of buckthorn, for about forty couple of hounds. In the winter season, the hounds should be shut up warm at night. If any hounds after hunting are missing, the straw house door should be left open; and if they have had a hard day, it may be as well to leave some meat there for them."

It is admitted that the hounds of this country are the best in the world; but it seems strange that they should degenerate in a foreign country: that this should be the case in the East or West Indies is not surprising, but that when taken to the Continent of Europe degeneracy should follow is a circumstance scarcely to be credited. The present race of English and Irish hounds were no doubt originally brought from the Continent (by the Nor-

mans); and therefore, when taken back again, the degeneracy complained of arises perhaps rather from neglect than any other cause. Thus sings Somervile :

“ In thee alone, fair land of liberty!  
Is bred the perfect hound, in scent and speed  
As yet unrivalled; while, in other climes,  
Their virtue fails, a weak degenerate race.”

Admitting that the original stock of the present race of hounds was imported from the Continent of Europe, we are very well aware, that more than ordinary pains have been taken ever since in their breeding and improvement; and the most reasonable way of accounting for the degeneracy complained of is by supposing that foreigners do not pay the requisite attention, indispensably necessary in order to keep up the breed.

In the matter of breeding a considerable portion of judgment is requisite, and

the sportsman will find much for reflection in the propagation of hounds. There are, however, fixed principles from which no deviation is allowable. The first consideration is the size, shape, constitution, disposition, and qualities of the dog from which to breed; and on no account should a dog be made use of for this purpose that is a skirter, that has not a fine nose, or that is not stout and capable of endurance. This subject is very well elucidated by Somervile:—

“ Observe with care his shape, sort, colour, size.  
Nor will sagacious huntsmen less regard  
His inward habits; the vain babbler shun,  
Ever loquacious, ever in the wrong,  
His foolish offspring shall offend thine ears  
With false alarms, and loud impertinence.  
Nor less the shifting cur avoid, that breaks  
Illusive from the pack; to the next hedge  
Devious he strays, there every meuse he tries,  
If haply then he cross the streaming scent,  
Away he flies vain-glorious; and exults  
As of the pack supreme, and in his speed  
And strength unrivalled. Lo! cast far behind  
His vext associates pant, and lab’ring strain  
To climb the steep ascent. Soon as they reach  
Th’ insulting boaster, his false courage fails,  
Behind he lags, doomed to the fatal noose,  
His master’s hate, and scorn of all the field.  
What can from such be hop’d but a base breed  
Of coward curs, a frantic, vagrant race? ”

It is the judicious cross that makes the complete pack. The faults and imperfections of one breed may be remedied in another; and if this be properly attended to, the breeding of hounds may improve till improvement can go no further. An old dog should never be put to an old bitch. The individuals from which the sportsman breeds should be healthy of course, or a healthy offspring is scarcely to be expected. Should a favourite dog skirt a little, he should be put to a thorough line hunting bitch, and such a cross is very likely to succeed:—the only objection there can be to breeding from such a hound is, that as skirting is what most fox-hounds acquire from practice, there is some danger of its thus becoming natural

to them. A famous sportsman asserted that he frequently bred from brothers and sisters: this, however, we feel no hesitation in condemning in the most unqualified manner, as, from experience, many times repeated, we well know that such a plan will not answer: the progeny not only are weaker and more puny, but positively lose their faculties.

The bitches should be cautiously watched, and separated as soon as they manifest the least symptoms of becoming proud; for, though in general the bitch will not admit the dog for several days, or perhaps a week, after she has exhibited the first signs of desire, yet it is advisable not to trust where there is even a remote probability of doing wrong. Moreover,

the advances bitches make frequently portend mischief as well as love ; and if not prevented in time, will not fail to set the whole kennel together by the ears, and

may occasion the death of some of the most valuable of its inhabitants—care only can prevent it—

“ Mark well the wanton females of thy pack,  
That curl their taper tails, and frisking court  
Their pyebald mates enamour'd ; their red eyes  
Flash fires impure ; nor rest, nor food, they take,  
Goaded by furious love. In sep'rate cells  
Confine them now, lest bloody civil wars  
Annoy thy peaceful state.——”

SOMERVILE.

Puppies should, if possible, be bred early in the year. Late puppies seldom come to much ; these, at all events, should be put to the best walks and well nursed. When the bitches begin to get big, they should hunt no more : it would prove fatal to the whelps, if not to the bitch herself ; nor is it safe for a bitch in an advanced state of gestation to remain in the kennel. Bitches will sometimes have an extraordinary number of whelps at a litter ; in which case, if they are great favourites, some of them should be put to another bitch ; or if this be not practicable, the sportsman must exercise his own judgment in regard to those which he keeps and those which he destroys. The bitches should be well fed while they have whelps upon them, and the whelps should remain with the bitch till they are able to take care of themselves. They will soon learn to lap milk, which will relieve the mother. The bitches, when their whelps are taken from them should be physicked. The distemper frequently makes dreadful havock with the whelps at their walks, which might be, in a great degree, prevented by proper management.—See the article DISEASES OF DOGS, page 217.

Beckford very judiciously observes—  
“ I have often heard, as an excuse for hounds not hunting a cold scent, that they were *too high bred*—I confess I know not what that means ; but this I know, that hounds are frequently *too ill bred* to be of any service. It is judgment in the breeder,

and patience afterwards in the huntsman that makes them hunt.”

Young hounds are generally named when first put out, and sometimes indeed ridiculously enough ; nor is it easy, where many are bred, to find suitable or harmonious names for all ; particularly as it is usual to name all the whelps of one litter, with the same letter, which (to be systematically done) should also be the initial letter of the dog that got them, or the bitch that bred them.

It is indeed of little consequence what huntsmen call their hounds, as long as the dogs understand when they are spoken to. It is not usual to call a pointer Rockwood, or a greyhound Harmony ; and such names as are expressive of speed, strength, courage, or other natural qualities in a hound may be regarded as most applicable to them. Some persons mark or brand their whelps, when they are first put out to prevent them being stolen, or if stolen, to lead to the recovery.

When young hounds are first taken in, they should be kept separate from the pack ; and as it happens at a time of the year when there is little or no hunting, one of the kennels, and the grass court adjoining, may be easily given up to them. They will frisk and play, and their gambols frequently end in a battle ; it is therefore less dangerous where they are equally matched.—What Somerville says on this subject, is not only very beautiful but much to the purpose :—

“ But here with watchful and observant eye,  
Attend their frolicks, which too often end  
In bloody broils and death. High o'er thy head  
Wave thy resounding whip, and with a voice  
Fierce-menacing o'er-rule the stern debate,  
And quench their kindling rage ; for oft in sport  
Begun, combat ensues, growling they snarl,  
Then on their haunches reared, rampant they seize  
Each other's throats, with teeth and claws, in gore

Besmeared, they wound, they tear, till on the ground  
 Panting, half dead, the conquer'd champion lies :  
 Then sudden all the base ignoble crowd,  
 Loud clamouring, seize the helpless worried wretch,  
 And, thirsting for his blood, drag different ways  
 His mangled carcase on th' ensanguin'd plain.  
 O breasts of pity void ! t'oppress the weak,  
 To point your vengeance at the friendless head,  
 And with one mutual cry, insult the fallen !  
 Emblem too just of man's degenerate race !"

It sometimes happens that a dislike is taken to some particular hound, when the safest way is to remove him ; or it is very probable his fellows will kill him ultimately. It is no uncommon occurrence for a feeder, when he hears the hounds quarrel, to halloo, in the first place, to stop them. He then goes in amongst them, and flogs every hound he can come near. How much more reasonable, as well as more efficacious, would it be, were he to see which were the combatants before he speaks to them. Punishment would then fall, as it ought, on the guilty only. In all packs there are some hounds more quarrelsome than the rest ; and it is from them all the mischief arises. If chastisement will not quiet them, it may be prudent to break their holders ; for, since they are not necessary for them for the meat they have to eat, they are not likely to serve them in any good purpose.

Young hounds should be fed twice a day, as they seldom take kindly at first to the kennel meat, and the distemper is very apt to seize them at this time. It is better not to round them till they are fully settled ; nor should it be put off till the hot weather, for then they would bleed too much. Some persons castrate dogs that are thin over the back, and also spay such bitches as will not be wanted to breed from. This is a practice we by no means recommend.

In breeding, the sportsman should be as little prejudiced as possible in favour of his own sort ; but should send his best bitches to the best dogs, wherever he can find them. Those who breed only a few hounds may by chance have a good pack ; whilst those who breed a great many (if at the same time they understand the business) reduce it to a certainty.

After the young hounds have been rounded, and are well reconciled to the kennel, know the huntsman, and begin to acknowledge their names, they should be then put into couples and walked out amongst sheep. Indeed, there is no harm in walking out the young hounds in couples as soon as they are taken into the kennel.

If any are particularly snappish and troublesome, the couples should be left loose about their necks in the kennel, till they become more reconciled to them. If any are more stubborn than the rest, they should be coupled to old hounds rather than to young ones ; and two dogs should not be coupled together when it can be avoided. As young hounds are at first awkward, it may be advisable to send only a few out at a time with the people on foot ; they will soon afterwards become handy enough to follow a horse, and care should be taken that the couples be not too loose, lest they should slip their necks out of the collar, and give trouble in catching them again.

When they have been frequently walked in this manner among sheep, a few may be uncoupled at a time, and such as offer to run after them must be chastised—in a little time, the cry of *'ware sheep* will stop them without the aid of the whip ; and the less the whip is used the better. With proper care and attention they will soon become ashamed at even looking at sheep ; but if once they are suffered to taste mutton, they will be reclaimed with the utmost difficulty, if at all. Various are the methods employed to break such dogs from sheep ; the best remedy, however, is supposed to be a ram.

*We repeat the following paragraph, which has already appeared under the article BREAKING DOGS.*

It but too frequently happens that young dogs manifest an inclination to hunt and worry sheep, which must be instantly corrected. If repeated severe floggings have not the desired effect, the dog should be either tied to a strong ram, leaving a sufficient length of cord to allow the ram to make a run ; or they should be confined together in a barn or some building. Flog the dog till he cries out, making use of the words *'ware sheep*. The ram will not fail to commence a furious attack upon him, and will butt him most violently. They should be kept together twenty minutes ; the ram will not fail to continue his butting, and it may

not be amiss to flog the dog several times during this period, making use of the words just mentioned at the same time. This will most likely prevent the dog ever looking at sheep afterwards; unless, perhaps, where he has absolutely bitten them before this system of correction was put in practice, in which case there is no mode of correction or punishment that can be depended on; for, although the dog may not even notice sheep in the presence of any person, yet he will be very apt, nevertheless, to steal away, as opportunity may offer, for the purpose of depredation:—when dogs once have tasted mutton, as before observed, they are never to be trusted. Instances, indeed, have occurred, when the dog, after having been a little butted, has fiercely turned upon the ram, which he would have torn in pieces, had he not been prevented; but a circumstance of this sort rarely occurs, and, in the instances here alluded to, the dogs were grown too old to be cured by this or any other method short of close confinement or a halter. If a young dog look earnestly at a sheep, he should be corrected; and if he persevere in repeating this suspicious preface, recourse should be had to the ram, as by far the most effectual method that can be adopted. A dog should be corrected, in fact, the moment he is observed to manifest the slightest inclination even to notice sheep; as he will, if not checked, first look, then chase, and ultimately worry them.

This subject reminds us of an anecdote related by Beckford:—“A late lord of my acquaintance (says he) who had heard of this method, and whose whole pack had often been guilty of killing sheep, determined to punish them, and to that intent, put the largest ram that he could find into the kennel. The men with their whips and voices, and the ram with his horns, soon put the whole kennel into confusion and dismay, and the hounds and ram were then left together. Meeting a friend soon after—‘Come (says he) come to the kennel, and see what rare sport the ram makes among the hounds: the old fellow lays about him stoutly, I assure you—egad, he trims them!—there is not a dog dares look him in the face! His friend, who is a compassionate man, pitied the hounds exceedingly, and asked if he was not afraid that some of them might be spoiled?—‘No, d—n them (said he), they deserve it, and let them suffer.’ On they went—all was quiet—they opened the kennel door, but saw neither ram, nor

hound. The ram by this time had been entirely eaten up; and the hounds, having filled their bellies, had retired to rest.”

This circumstance carries with it its own commentary—what could be so thoughtless as to turn an unfortunate ram into a kennel of hounds! A single hound is a comparatively innocent and even cowardly creature:—a pack of hounds are the very reverse, each individual of which it is composed acquires an emulative courage, which, singly, he does not possess; or, at least, which he never exhibits.

Hounds should be frequently aired; and it may be advisable to take the old ones out one day, and the young ones another; or, if they are taken out together, the young ones should be in couples, unless they have become very tractable and obedient. Young hounds are always ready for any kind of mischief, and idleness might make even old ones too ready to join them in it.

When young hounds are to be stooped to a scent, it is most advisable to enter them at their own game—it will save much trouble afterwards. Many dogs, it is said, like that scent best to which they are first blooded; be this as it may, it is certainly most reasonable to use them to that which it is intended they should hunt. It may not be amiss, when they first begin to hunt, to put light collars upon them; as young hounds may easily get out of their knowledge; and shy ones, after they have been much beaten, may not choose to return home. Collars, in such cases, may prevent them being lost. Trail scents are by no means advisable for young hounds:—nor can any thing be more absurd than entering young fox hounds at hare.

“I know an old sportsman (says Beckford) a clergyman, who enters his young hounds first at a cat, which he drags along the ground for a mile or two, at the end of which he turns out a badger, first taking care to break his teeth; he takes out about two couple of old hounds along with the young ones, to hold them on. He never enters his young hounds but at vermin; for, he says, ‘train up a child in the way he should go, and when he is old he will not depart from it.’”

Summer hunting, though indispensable to young hounds, is prejudicial to old ones; it is advisable, therefore, to reserve a few of the best draft hounds for the purpose of entering the young ones with, selecting such as are most likely to set them a good example. They should not

be skirthers, but fair hunting hounds, such as love a scent, and that hunt closest on the line of it: it will be necessary that some of them should be good finders, and all must be steady. Thus the best instructions are procured for the young hounds, and at the same time this method prevents two evils, which would ensue were they taught by the whole pack; one, that of corrupting and getting into scrapes such as are not much wiser than themselves; and the other, that of occasioning much flogging and rating, which always shies and interrupts the hunting of an old hound. An old hound is a sagacious animal, and is not fond of trusting himself in the way of an enraged whipper-in, who, as experience has taught him, can flog, and flog unjustly.

As to the time for entering young hounds, that must depend on the country, or at least on the corn being cut: they should be entered as soon as possible; and, of course, in grass countries, summer or cub hunting may be commenced sooner than in districts where much corn is grown; and in woodlands it may be commenced almost at any time. If there are plenty of foxes, so that a sacrifice can be made of some of them, for the purpose of making the young hounds steady, they should be taken first where the least riot is likely to ensue, and if a litter can be found, there will be but little trouble with the young hounds afterwards.

Some are of opinion that such young hounds as are the most riotous at first become ultimately the best dogs. If, owing to a scarcity of foxes, young hounds should be stooped at hare, they should not be suffered to have the blood of her; nor should they receive much encouragement. Hare hunting has one advantage—hounds are chiefly in open ground, where you can easily command them; but notwithstanding that, if foxes are in tolerable plenty, they should be kept to their own game.

With young hounds, frequent hallooing is serviceable:—it keeps them forward, prevents their being lost, and hinders them from hunting after the rest. The oftener, therefore, a fox is seen and halloed the better: it serves to let them in, makes them eager, induces them to exert themselves, and teaches them to be handy. However, though much hallooing may be advisable with young hounds, this is certainly not the case with old ones; yet, it may be justly observed, that there is a time when hallooing is of use, a time

when it is injurious, and a time when it is perfectly indifferent; but it is long practice and great attention that must teach the application.

Young hounds, at their first entering, cannot be encouraged too much.—When they are become handy, are fond of a scent, and begin to know what is *right*, it will be soon enough to chastise them for what is *wrong*; in which case, one severe flogging will save much trouble. Whenever a hound is flogged, the voice should be used as well as the whip; and the smack of the whip will often be found sufficiently effective to a hound that has already felt the lash. If any young hounds are unsteady, it may not be amiss to send them out by themselves.

If hounds are to be made steady from deer, they should see them often; and if, after the necessary probation, a cub is turned down before them, with some old hounds to lead them on, they will not be long unsteady.

Flogging hounds in kennel is unreasonable, unjust, and cruel. It is true, hounds that are old offenders, that are very riotous, and, at the same time, very cunning, may be difficult to catch—such hounds may be excepted—they deserve punishment whenever it happens, and it ought to be administered to them: the peace however and quiet of the kennel should not be often thus disturbed. When hounds offend, they should be punished; when caught in the fact, then let them suffer if possible.

When young hounds will stoop to a scent, are become handy, know a rate, and stop easily, they should be put into the pack—a few at a time only; nor is it perhaps well to do this till the pack have been out a few times by themselves, and are got well in blood. And when young hounds are taken out for the first time, it should be in a place where it is probable a fox will be immediately found.

The following admirable observations appear in Beckford's Letters:—"I was told the other day by a sportsman, that he considers the management of hounds as a regular system of education, from the time when they are first taken into the kennel: I perfectly agree with that gentleman; and am well convinced that, if you expect sagacity in your hound when he is old, you must be mindful what instruction he receives from you in his youth; for, as he is of all animals the most docile, he is also most liable to bad habits. A diversity of character, consti-

tution, and disposition, is to be observed among them, which, to be made the most of, must be carefully attended to, and treated differently."

Hounds should be often walked out among sheep, hares, and deer; it uses them to a rate. If hounds find improper game, and hunt it, they should be stopped and brought back; and as long as they will stop at a rate, they should not be chastised. Obedience is all that can be required of hounds, till they have been sufficiently taught the game they are to pursue: an obstinate deviation from it afterwards should never be pardoned.

Beckford says his huntsman "sometimes turns down a cat before the young hounds, which they hunt up to and kill; and, when the time of hunting approaches, he turns out badgers or young foxes, taking out some of the steadiest old hounds to lead them on—this teaches them to hunt. He draws small covers and furze brakes with them, to use them to a halloo, and teach them obedience." However, to keep hounds to the game they are intended to hunt, and that game only, is by far the best plan, whenever it is practicable; nor can this observation be too forcibly impressed on the minds of sportsmen. Beckford has a concluding salvo.—He observes—"When they begin to hunt (that is, young hounds) they are first taken into a large cover of my own, which has many ridings cut in it; and young foxes are turned out every year on purpose for them. *Here* it is they are taught the scent they are to hunt, are encouraged to pursue it, and are stopped from every other. *Here* they are blooded to fox. I must also tell you, that as foxes are plentiful in this cover, the principal earth is not stopped, and the foxes are checked back, or some of them let in, as may best suit the purpose of blooding. After they have been hunted a few days in this manner, they are then sent to distant covers, and more old hounds are added to them: there they continue hunting till they are taken into the pack, which is seldom later than the beginning of September; for by that time they will have learned what is required of them, and they seldom give much trouble afterwards. In September I begin to hunt in earnest, and after the old hounds have killed a few foxes, the young hounds are put into the pack, two or three couple at a time, till all have hunted. They are then divided; and as I seldom have occasion to take in more than nine or ten couple,

one half are taken out one day, and the other half the next, till all are steady.

"Two other methods of entering young hounds I have occasionally practised, as the number of hounds have required: for instance, when that number is very considerable, I make a large draft of my steadiest hounds, which are kept with the young hounds in a separate kennel, and are hunted with them all the fore part of the season. This, when the old hounds begin to hunt, makes two distinct packs, and is always attended with great trouble and inconvenience. Nothing hurts a pack so much as to enter many young hounds, since it must weaken it considerably by robbing it of those which are the most steady; and yet young hounds can do nothing without their assistance. Such, therefore, as constantly enter their young hounds in this manner, will, sometimes at least, have two indifferent packs, instead of one good one.

"In the other method, the young hounds are well awed from sheep, but never stooped to a scent till they are taken out with the pack; they are then taken out a few only at a time; and if your pack is perfectly steady and well manned, may not give you much trouble. The method I first mentioned, which is the one I most commonly practise, will be necessary when you have many young hounds to enter; when you have only a few, the last will be most convenient."

There is more circumspection necessary in the education of young hounds than may at first sight be imagined. For instance, one halloo of encouragement to a wrong scent causes endless mischief, or, in other words, undoes all that has been previously accomplished.

The day that it is intended to turn down a fox before young hounds, it will be as well to send them among deer or hares, or both. A little rating and flogging, before they are encouraged, is of the greatest service, as it teaches them what they ought, and what they ought not, to do. Though bag foxes may be turned down before young hounds, they should not be shook before old dogs.

The day after young hounds have had blood is a proper time to send them where there is riot, and to chastise them if they deserve it:—it is always best to correct them, when they cannot help knowing what they are corrected for. When hounds are sent out for this purpose, the later they go the better, as the worse the scent is, the less inclinable will they be to

run it, and of course will give less trouble in stopping them. It has been already observed, that to flog hounds in the kennel is a very injudicious, and consequently a very censurable, plan; but if many hounds are obstinately riotous, a living hare might be put into the kennel to them; they should be flogged as often as they approach her; they will then have some notion for what they are beaten; but no steady hounds should be present on such an occasion. When a hare is put into the kennel, the huntsman and both the whippers-in should be present; and the whippers-in should flog every hound, calling him by his name, and rating him as often as he goes near the hare; and upon this occasion they cannot cut them too hard, or rate them too much; when they think they have chastised them enough, the hare should then be taken away, the huntsman should halloo off his hounds, and the whippers-in should rate them to him. If any love hare more than the rest, a dead hare may be tied round his neck, flogging and rating him at the same time.

Young hounds should be hunted in the large covers; it will tire them out; a necessary step towards making them steady; moreover, it will open the cover against the time hunting is commenced in earnest; and by disturbing the large covers early in the season, foxes will be shy of them, and shew better chases: besides, as they are not likely to break from thence, no injury will be done to the cover, even should it not be yet cut.

Should hounds be very riotous, and require stopping very often from hare, it will be advisable to try on, however late in the day, till a fox is found, as the giving them encouragement should, at such a time, prevail over every other consideration.

Though all young hounds are given to riot, yet the better they are bred, the less trouble they will give. Such, however, as are very riotous, should have little rest; they should be hunted one day in large covers where foxes are in plenty; the next day they should be walked out amongst hares and deer, and stopped from riot; the day following, be hunted again as before.—“Old hounds (says Beckford) that I have had from other packs (particularly such as have been entered at hare) I have sometimes found incorrigible; but I never yet knew a young hound so riotous, but, by this management, he soon became steady.”

When hounds are rated, and do not attend to the rate, they should be coupled up immediately, and be made to know the whipper-in;—and in all probability this method will save any further trouble.

Some are of opinion that martens are very proper objects at which to enter young hounds; and that the marten, being a small animal, by running the thickets breaks it can find, teaches hounds to run cover, and is therefore of the greatest utility.

In summer, hounds may hunt in an evening. Scent generally lies well at the close of the day; yet there is an objection to hunting at that time; animals are then more easily disturbed, and consequently there will be a greater variety of scents than at an earlier hour.

In regard to the hour of going out in a morning, we are informed that the sportsmen of the old school used to be at the side of the cover by break of day, and this is mentioned in a tone of triumph, accompanied with an affectation of contempt for the custom of modern sportsmen; there are other matters, still more ridiculous, upon which those who pretend to admire the customs of yore, speak with rapture. The hour most favourable for finding is no doubt an early one, but it by no means follows that it is equally as good for pursuing the chase as a later period of the day; on the contrary, when in the early part of the morning, there is a sharp frost, the state of the atmosphere is not so favourable for scent, and consequently to the running of the dogs, as when, an hour or two afterwards, the day has become fine, and the ground much better calculated for hunting. If the hour of meeting be not later than ten o'clock, there can be no reason to complain.

On this subject, Beckford seems not to have written with his usual acuteness and penetration.—He says, “At an early hour, you are seldom long before you find.” This is true enough. But he continues—“*The morning is the time of the day which generally affords the best scent.*” This is an error, as the reasons already given sufficiently prove. In fact, Beckford, from observing that foxes were more readily found early in the morning, has hastily concluded that it “affords the best scent;” whereas, the reason of the fox being more easily found is because the hounds thus come on the *drag* in a very short time after the fox has passed to his kennel—and hence has no doubt

arisen Beckford's erroneous notion. He proceeds, "the animal himself which we are more than ever, in such case, desirous of killing (Beckford is here supposing hounds are in want of blood), is then least able to run away from you. The want of rest, and perhaps a full belly, give hounds a great advantage over him.—I expect, my friend, that you will reply to this, 'that a fox hunter then is not a *fair sportsman*.' He certainly is not; and what is more, would be very sorry to be mistaken for one. He is otherwise from principle. In his opinion, a fair sportsman and a foolish sportsman, are synonymous; he, therefore, takes every advantage of the fox he can. You will ask, perhaps, if he does not sometimes spoil his own sport by this? It is true, he sometimes does, but then he *makes* his hounds; the whole art of fox hunting being to keep the hounds well in blood. Sport is but a secondary consideration with a true fox hunter. The first thing is, *the killing of the fox*—hence arises the eagerness of pursuit, and the chief pleasure of the chase. I confess I esteem blood so necessary to a pack of fox hounds, that, with regard to myself, I always return home better pleased with an indifferent chase and death at the end of it, than with the best chase possible, if it ends with the loss of the fox. Good chases, generally speaking, are long chases; and, if not attended with success, never fail to do more harm to the hounds than good. Our pleasures, I believe, for the most part, are greater during the expectation than the enjoyment. In this case, reality itself warrants the idea, and your present success is almost a sure forerunner of future sport."

Hounds should always draw up the wind, and the sportsmen should remain quiet, unless indeed the covers are small, or such as a fox cannot break away from unseen, in which case noise can do no harm. If it be late in the day when the cover is drawn, and there is no drag, then the more the cover is disturbed the better—a fox is thus more likely to be found. Late in the season, foxes generally are wild, particularly in covers that are often hunted. If the cover be not drawn quietly, the fox will sometimes get off a long way before:—when any suspicion of this is entertained, a whipper-in should be sent on to the opposite side of the cover before the hounds are thrown in.

In regard to sportsmen, Beckford thus expresses himself in writing to his friend:

—"You think I am too severe on my brother sportsmen. If I am more so than they deserve, I am sorry for it. I know many gentlemen, who are excellent sportsmen; yet, I am sorry to say the greater number of those who ride after hounds are not; and it is to those only that I allude. Few gentlemen will take any pains—few of them will stop a hound, though he should run riot close beside them, or will place themselves for a moment, though it be to halloo a fox; it is true, they will not fail to halloo, if he comes in their way, and they will do the same to as many foxes as they see.—Some will encourage hounds which they do not know; it is a great fault: were every gentleman who follows hounds to fancy himself a huntsman, what noise, what confusion would ensue! I consider many of them as gentlemen riding out, and I am never so well pleased as when I see them riding home again. You may perhaps have thought that I wished them all to be huntsmen.—Most certainly not; but the more assistance the huntsman has, the better in all probability the hounds will be. Good sense and a little observation will soon prevent such people from doing amiss; and I hold it as an almost invariable rule in hunting, that those who do not know how to do good, are always liable to do harm: there is scarce an instant during the whole chase, when a sportsman ought not to be in one particular place; and I will venture to say, if he is not there, he might as well be in bed."

There are two things in regard to hounds which should be particularly attended to—the one is, to make them steady, the other to make them all draw. Many huntsmen are fond of having them at their horse's heels; but they can never get so well, or so soon, together, as when they spread the cover; besides, it has often happened where there have only been a few finders, that they have found their fox, gone down the wind, and been no more heard of that day. Hence, also, a good reason why hounds should draw up the wind; and on this subject it may be further observed, that when hounds draw up wind, the fox does not hear them approach; and the hounds are thus never out of hearing; besides, if the fox turns down the wind, as most probably he will, it lets all the hounds in.

There is infinite pleasure in hearing a fox well found. When the hounds get up to his kennel with a good drag, the chorus increasing as they go, it inspires an

extasy more easy to feel than describe; and Beckford says one fox found in this lively manner is worth the best hare chase that was ever run.

Much depends on the first finding of the fox, since a fox well found may be considered as half killed. But people in general are apt to be in too great a hurry on this occasion. There is an enthusiasm attending this diversion which in this instance in particular ought to be restrained. The hounds are always mad enough when they find their fox; if the men also are mad, it becomes mad work indeed. The following anecdote is related of a gentleman who well knew the bad consequences of what has just been mentioned. When the fox was found, he began by taking a pinch of snuff, he then sung part of an old song—“*Some say care killed the cat,*” &c. By this time, his hounds were got well together, and settled to the scent. He then hallooed and rode as if the devil drove.—However, the writer cannot help thinking, that should any person attempt the practice of this system with many of the modern packs, he would have some difficulty in afterwards reaching them—he might think himself singularly fortunate if he saw them again.

The huntsman should set off with the leading hounds; and he should keep as close to them afterwards as he conveniently can; nor can any harm arise from it, unless he has not common sense. No hounds can slip down the wind and get out of his hearing; he will also see how far they carry the scent; a necessary knowledge, for without it, he can never make a cast with any degree of certainty.

The huntsman should also be active in pressing the hounds forward when the scent is good; as well as prudent in not hurrying them beyond it when it is bad. A huntsman should of course be a good horseman; if he is not, he cannot possibly be of much use; since one of his leading qualifications should be to ride well up to his head hounds. It is his business to be ready at all times to lend them that assistance they so frequently stand in need of, and which, when they are first at a fault, is then most critical. A fox-hound, at that time, will exert himself most; he afterwards cools, and becomes more indifferent about his game. Those huntsmen who do not get forward enough to take advantage of this eagerness and impetuosity, and direct it properly, seldom know enough of hunting to be of much use to them afterwards.

It is sometimes more difficult to keep the whipper-in back than to get the huntsman forward. It is however necessary; nor will a good whipper-in leave the cover while a single hound remains in it; for this reason there should be two, one of which should be always forward with the huntsman. There are many ills that may happen to hounds that are left behind; and the surest way of keeping them steady is keeping them together. When left to themselves, they seldom refuse any blood they can get; they acquire many bad habits; they become conceited, a great fault in any animal; and they learn to tye upon the scent—an unpardonable fault in a fox-hound; besides which, they frequently get a trick of hunting by themselves, and are seldom worth much afterwards. The lying out in the cold, perhaps, the whole night can do no good to their constitutions; nor will the being worried by sheep-dogs or mastiffs be of service to their bodies: all this, however, and much more, they are liable to.

Every country is soon known, and nine foxes out of ten, with the wind in the same quarter, will follow the same track. It is easy therefore for the whipper-in to cut short, and catch the hounds again.

With a high scent, hounds cannot be pushed on too much.—Halloos keep the fox forward, at the same time that they keep the hounds together, or let in the tail hounds; they also enliven the sport; and, if discreetly given, are always of service; but in cover they should be used with the greatest caution.

Most fox hunters wish to see their hounds run in a good style. They should, as much as possible, as already observed, run abreast; nothing can be more unpleasant than to see a string of them, or to see them creep where they can leap. It is the dash of the fox-hound which distinguishes him. A pack of harriers, if they have time, will kill a fox; but they cannot kill him in the style in which he ought to be killed—they must hunt him down. Beckford remarks that the duration of a chase should not be less than one hour, nor more than two; it is sufficiently long, if properly followed; many of the modern chases, however, are over in a much shorter time, owing to the uncommon speed of the hounds.

Hounds should not be kept too long; after five or six seasons they generally do more harm than good: if they tye upon the scent, and come hunting after, they

should immediately be destroyed, let their age be what it may : there is no getting such hounds forward ; they will never come to a halloo, (which every hound that is off the scent, or behind the rest, should not fail to do) and are always more liable to draw you back than to help you forward.

Changing from the hunted fox to a fresh one, is one of the worst accidents that can happen to a pack of fox-hounds ; and it requires all the observation and all the ingenuity that man is capable of to guard against it. Shaw, the favourite huntsman of the Duke of Rutland, and now living, I believe, though retired, occasionally displayed much acuteness and sagacity in this respect. The writer recollects this man once persisting in this respect against the voice of the united field, and he persisted successfully. The Duke of Rutland's hounds ran the fox into a small cover at the edge of the Vale of Belvoir : a fox was tallyhoed on the other side of the cover by a countryman, and the hounds immediately got to the place, and were running :—Shaw, however, stopped them, insisting that the hunted fox was still in the cover ; and he took his hounds back, contrary to all remonstrance and to the general opinion : but he was right ; he recovered the original chase and killed him.

Could a fox-hound distinguish the hunted fox as the deer-hound does the deer that is blown, fox-hunting would then be perfect ; this, at least, is the position of Beckford ; but it requires elucidation :—Deer-hounds, to distinguish the blown deer from the herd, must be bred very near the old talbot or blood-hound, since it is by exquisite olfactory organs that this nice distinction can be made. Such stag hounds as were used by the Earl of Derby are unable to do this—they are not bred sufficiently near the talbot for this purpose ; and, most probably, if fox-hounds possessed the requisite breeding, the hunted fox might be as easily distinguished as the blown deer.

There are certain rules that ought to be observed by a huntsman : he should always listen to his hounds whilst they are running in cover ; he should be particularly attentive to the head hounds, and he should be constantly on his guard against a skirter ; for, if there are two scents, he must be wrong.—Generally speaking, the best scent is least likely to be that of the hunted fox ; and as a fox seldom suffers hounds to run up to him, as long as he is

able to prevent it, so, nine times out of ten, when foxes are hallooed early in the day, they are all fresh foxes. The hounds most likely to be right are the hard-running, line-hunting hounds ; or such as the huntsman knows had the lead before there arose any doubt of changing.

With regard to the fox, if he breaks over an open country, it is no sign that he is hard run ; for they seldom, at any time, will do that, unless they are a great way before the hounds. Also, if he runs up the wind,—foxes seldom do that when they have been long hunted and grow weak ; and when they run their foil, *that* also may direct the huntsman. All this requires a good ear and nice observation, and, indeed, in these consist the chief excellence of a huntsman.

When hounds divide, and are in two parts, the whipper in, in stopping, must attend to the huntsman, and wait his halloo, before he attempts to stop either ; lest, for want of proper management in this particular, the hounds should be stopped at both places, and both foxes lost by it. If they have many scents, and it is quite uncertain which is the hunted fox, let him stop those that are farthest down the wind, as they can hear the others, and will reach them soonest : in such a case, there will be but little use in stopping those that are up the wind.

When hounds come to a check, every one should be silent. Whippers-in are frequently at this time coming on with the tail hounds. They should never halloo to them when hounds are at fault : the least thing does hurt at such a time, but a halloo more than any other. The huntsman, at a check, had better let his hounds alone, or content himself with holding them forward, without taking them off their noses. Hounds that are not used to be cast, will of themselves acquire a better cast than it is in the power of any huntsman to give them ; will spread more and try better for the scent ; and, if they are in health and spirits, they will want no encouragement.

If they are at fault, and have made their own cast, which the huntsman should always encourage them to do, it is then his business to assist them further ; but, except in some particular instances, they should never be cast as long as they are inclined to hunt. The first cast of a huntsman should be a regular one : if that does not succeed, he should be at liberty to follow his own opinion, and proceed as observation and genius may direct.

When a knowing cast is made, there ought to be some mark of good sense or meaning in it—whether down the wind, or towards some likely cover or strong earth: however, as it is at best uncertain, and as the huntsman and the fox may be of different opinions, a regular cast should always be made before a knowing one is attempted; which, as a last resource, should not be called forth till it is wanted. The letting hounds alone is but a negative goodness in a huntsman; whereas it is true that this last gives him an opportunity of displaying genius, if he happen to possess so rare and valuable a qualification. There is one fault, however, which a knowing huntsman is apt to commit—he will find a fresh fox, and then claim the merit of having recovered the hunted one.

It is always dangerous to throw hounds into a cover to retrieve a lost scent; and, unless they hit him in, is not to be depended on. Driven to the last extremity, should a knowing cast not succeed, the huntsman is no way blamable.

When hounds are at fault, gentlemen are apt to contribute to their remaining so. They should always stop their horses some distance behind the hounds; and, if it is possible to be silent, this is the time to be so: they should be careful not to ride before the hounds or over the scent; nor should they ever meet a hound in the face unless with a design to stop him. Should a sportsman, at any time, happen to get before the hounds, he should turn his horse's head the way they are going, get out of their way, and let them pass.

When the weather is dry, foxes will run the roads, particularly in heathy countries. If gentlemen, at such a time, ride close upon the hounds, they may drive them miles without any scent. High mettled fox-hounds are seldom inclined to stop whilst horses are close at the heels of them.

It has been said of a good sportsman, but a very warm one, that when he saw any of the company pressing too close upon his hounds, he began calling out—Hold hard!—If any one, after that, persisted, he began moderately, at first, by saying, “I beg, Sir, you will stop your horse:—Pray, Sir, stop:—God bless you, Sir, stop:—God d—n your blood, Sir, stop your horse!”

The first moment that hounds are at fault is a critical one for the sport: sportsmen should then be very attentive. Those who look forward perhaps may see the

fox; or, the running of sheep, or the pursuit of crows may give them some tidings of him. Those who listen may sometimes take a hint which way he is gone from the chattering of a magpie, or perhaps be at a certainty from a distant halloo: nothing that gives any intelligence at such a time as this should be neglected.—Gentlemen are too apt to ride all together: were they to spread more, they might sometimes be of service; particularly such, as from a knowledge of the sport, keep down the wind; it would then be difficult for either hounds or fox to escape their observation.

The huntsman should be very cautious how he goes to a halloo. The halloo must, in a great measure, direct him; and, though it afford no certain rule, yet something like an opinion may be formed, whether it is to be depended on, or not. At sowing time, when boys are scaring birds, a huntsman may sometimes be deceived by their halloo if he be not very much on his guard. When any doubt is entertained, it is most advisable to send a whipper-in to ascertain the real state of the case, as the worst then that can happen is the loss of a little time; whereas, if the huntsman gallop away with the hounds to the halloo, and is obliged to return, it is a chance if the hounds will try for the scent afterwards; on the other hand, if the halloo is to be depended on, the sooner the hounds get to it the better. Huntsmen who are slow of getting to a halloo are void of common sense. They frequently commit another great fault, by being in too great a hurry when they get there. It is hardly credible how much our eagerness is apt at such a time to mislead our judgment; for instance, when we get to the halloo, the first questions are natural enough—Have you seen the fox?—which way did he go?—The man points with his finger perhaps, and then away you all ride as fast as possible; and in such a hurry that not one will stay to hear the answer which you were all so desirous of knowing; the general consequence of which is, you mistake the place, and are obliged to return to the man for better information. The less hurry on such occasions, however, the better; and wherever the fox was seen for a certainty, whether near or distant, that will not only be the surest, but also the best, place to take the scent.

The idea that a fox never stops is a very necessary one for a fox hunter, that he may be active, and lose no time; yet tired

foxes will stop if you can hold them on; and they have been known to stop even in wheel ruts on the open down, and leap up in the midst of the hounds. A tired fox ought not to be given up; for he is killed sometimes very unexpectedly. If hounds have ever pressed him, he is worth your trouble; perseverance may recover him, and, if recovered, he most probably will be killed; nor should you despair while any scent remains. The business of a huntsman is only difficult when the scent dies quite away; and it is then he may shew *his* judgment, when the hounds are no longer able to shew *their's*. The recovering a lost scent, and getting near to a fox by a long cast, requires genius, for which huntsmen in general are not remarkable. When hounds are no longer capable of feeling the scent, it all rests with the huntsman; either the game is entirely given up, or is only to be recovered by him.

When hounds are at cold hunting, with a bad scent, it is a good time to send a whipper-in forward; if he can see the fox, a little mobbing at such a time as this may reasonably be allowed.

If hounds come to a check on the high road by the fox being headed back, if in that particular case, you suffer them to try back, it gives them the best chance of hitting off the scent again, as they may try both sides at once.

When hounds are running in cover, you cannot be too quiet. If the fox be running short, and the hounds are killing him, not a word should then be said: it is a difficult time for hounds to hunt him, as he is continually turning, and will sometimes lie down and let them pass him.

The greatest danger perhaps of losing a fox is at the first finding him, and when he is sinking; at both of which times he frequently will run short, and the eagerness of the hounds is too apt to carry them beyond the scent. When a fox is first found, every one should keep behind the hounds till they are well settled to the scent; and when they are killing him, every one should be as silent as possible.

"When he is caught, (says Beckford) I like to see hounds eat him eagerly. In some countries, I am told, they have a method of *treeing* him: it is of use to make the hounds eager; it lets them all in; they recover their wind, and eat him more readily." He should not, however, be kept too long, as the hounds will perhaps manifest no inclination to eat him

longer than while they are angry with him.

When a fox is hallooed, those who understand the business may get forward, and halloo him again; yet, let it be understood, if the hounds go the contrary way, or do not seem to come on upon the line of him, they should halloo no more. With regard to its being the hunted fox, the fox which every man halloos is the hunted fox in his own opinion, though he seldom has a better reason for it than because *he* saw him. Such halloos as serve to keep the hounds together, and get on the tail hounds, are always of use: it is the halloos of encouragement to the leading hounds, when injudiciously given, that is very apt to spoil the sport. View halloos frequently do more harm than good. They are pleasing to sportsmen, but prejudicial to hounds. If a strong cover be full of foxes, and they are often hallooed, hounds seldom take much pains in hunting them—hence arises that coldness and indifference which sometimes may be perceived in hounds whilst pursuing their game.

Hounds should never be taken off to a halloo when they are running with a good scent; but if otherwise, and the halloo can be depended on—for instance, when the fox is a great way before them, or persists in running his foil, such a step may be advisable; for such foxes are difficult to kill unless you get nearer them by some means or other.—When you hunt often thus, it frequently happens, that the longer you run, the further you are behind.

When hounds are out of blood, and a fox runs his foil, you need not scruple to stop the tail hounds and throw them in at head; or, if the cover has any ridings in it, and the fox be often seen, the huntsman, by keeping some hounds at his horse's heels, at the first halloo that he hears may throw them in close at him. This will put the fox out of his pace, and perhaps put him off his foil.—It will be necessary, when this is done, that the whipper-in should stop the pack from hunting after him, and get forward with them to the huntsman.

Hounds may be hallooed too much, as already observed. If they are often used to a halloo, they will expect it, and may perhaps trust to their ears and eyes more than to their noses. If they are often taken from the scent, it teaches them to shuffle, and will probably make them slack in cover: it should be done, therefore, with

great caution—not too often, and always should be well timed. Whilst hounds can get on with the scent, it cannot be right to take them off from it; but when they are stopped for want of it, it cannot then be wrong to give them every possible advantage.

Hounds should not be suffered to hunt after others that are gone on with the scent, as they are never likely to reach them with a worse scent; besides it induces them to tye on the scent, hunt dog, and destroys that laudable ambition of getting forward which is the chief excellence of the fox-hound.

A good huntsman will seldom suffer his hounds to run away from him; if it should so happen, and they are still within his hearing, he sinks the wind with the rest of the pack, and gets to them as fast as he can. When a single hound is gone on with the scent, a whipper-in should be sent forward to stop him; were the hounds to be taken off the scent to get to him, and he should no longer have any scent when they reach him, the fox would, in all probability, be lost by it. This is a reason why in large covers, and particularly such as have many roads in them, skirting hounds should be left at home on windy days.

Skirting is a bad quality in men as well as in dogs. Such as skirt to save themselves or their horses, often head the fox. Good sportsmen never quit hounds but to be of service to them: with men of this description, skirting becomes a necessary part of fox hunting and is of the greatest use. "Skirters! beware of a furze brake (exclaims the author from whom we have so often quoted); if you head back the fox, the hounds most probably will kill him in the brake. Such as ride *after* hounds, at the same time that they do no good, are the least likely to do harm:—let such only as understand the business, and mean to be of service to the hounds, ride wide of them. I cannot, however, allow that the riding close up to the hounds, is always the sign of a good sportsman; if it were, a monkey on horseback would be the best sportsman. Here must I censure (but with respect) that eager spirit which frequently interrupts, and sometimes is fatal to, sport in fox hunting; for, though I cannot subscribe to the doctrine of my friend—'that a pack of fox-hounds would do better without a huntsman than with one; and that if left to themselves they would never lose a fox;' yet, if allowing them their usual

attendants, he had objected only to the sportsmen who follow them, I must have joined issue with him. Whoever has followed hounds has seen them frequently hurried beyond the scent; and whoever is conversant in hunting must know, that the steam of many horses, carried by the wind, and mixed with a cold scent, is prejudicial to it."

It sometimes happens that a good horseman is not so well in with the hounds, as an indifferent one, because he will not condescend to get off his horse. The best way to follow hounds across a country is to keep on the line of them (says Beckford) and "to dismount at once, when you come to a leap you do not wish to take; for, in looking about for easier places much time is lost." What would the Meltonians say to this?—they would object to that part, no doubt, which advises the sportsman to dismount.

In following hounds, it may be useful to know, that, when in cover they run up the wind, you cannot in reason be too far behind them, as long as you have a perfect hearing of them, and can command them; and, on the contrary, when they are running down the wind, you cannot keep too close to them.

When covers are much disturbed, foxes will sometimes break away as soon as they hear a hound. Where the country round is very open, the fox least likely to break is the one which you are hunting; *he* will be very unwilling to quit the cover, if it be a large one, unless he can get a great distance before the hounds. If sportsmen are desirous of a run over such a country, the likeliest means will be to post a quiet and skilful person to halloo one off, and lay on to him. The further he is before the hounds, the less likely he will be to return. The best method, however, of hunting a cover like this, which is full of foxes, is to stick constantly to it, not suffering the hounds to break so long as one fox remains:—if this be done two or three hunting days in succession, foxes will then fly, and good runs may be obtained.

Frequently changing the country is prejudicial to hounds: should they change from a good scenting country to a bad one, they will be some time before they kill a fox, unless they have better luck than ordinary; whereas, hounds have always a great advantage in a country which they are used to. They not only know better where to find their game, but they will pursue it with more energy when they have found it.

A good whipper-in, according to Beckford, is not less essential to a pack of fox-hounds, than a good adjutant is to a regiment. And speaking of the huntsman, he says, that he is not very ambitious to have a *famous* huntsman "unless it necessarily followed that he must have *famous hounds*; a conclusion I cannot admit, so long as these, so famous gentlemen, will be continually attempting to do themselves, what it would be much better if they would permit their hounds to do: besides, they seldom are good servants, are always conceited, and sometimes impertinent. I am very well satisfied if my huntsman knows his country, knows his hounds, and rides well up to them, and has some knowledge of the nature of the animal he is in pursuit of; and so far am I from wishing him to be *famous*, that I hope he will continue to think that his hounds know best how to hunt a fox."

He continues—"You say you agree with me, that a huntsman should stick close to his hounds. If then his place is fixed, and that of the first whipper-in is not, I cannot help but think genius may be at least as useful in one as in the other: for instance, while the huntsman is riding to his head hounds, the whipper-in, if he has genius, may shew it in various ways: he may clap forward to any great earth that may by chance be open; he may sink the wind to halloo or mob a fox, when the scent fails; he may keep him off his foil; he may stop the tail hounds and get them forward; and has it frequently in his power to assist the hounds, without doing them any hurt, provided he has sense to distinguish where he is wanted most. Besides, the most essential part of fox hunting, the making and keeping the pack steady, depends entirely upon him: as a huntsman should seldom rate, and never flog, a hound. In short, I consider the first whipper-in as a second huntsman; and, to be perfect, he should be as capable of hunting the hounds as the huntsman himself."

A whipper-in should always get to the head of his hounds before he attempts to stop them. The rating behind is to little purpose; and, if they are in cover, may prevent him from knowing who the culprits are. When hounds are running a fox, he should content himself with stopping such as are riotous, and should get them forward. They may be condemned upon the spot, but the punishment deferred till the next day, when they may be

taken out on purpose to commit the fault, and suffer the punishment.

Young hounds cannot be awed too much; yet their punishment should not exceed the measure of their offence—a line should be drawn between justice and barbarity.

A whipper-in, while breaking young hounds, will sometimes rate them before they commit the fault: this prevents them for that time; but they will be just as ready to begin the next opportunity. He should let them alone, till he perceives what they would be at; and the discipline then should be proportioned to the offence, as already observed.

Whether a riotous young hound runs little or much, it is of small consequence, if he be not encouraged: it is the blood only that signifies, which in every kind of riot should be carefully prevented.

Whippers-in are too apt to continue rating, even when they find rating does not avail. There is but one way to stop such hounds, which is, to get to the heads of them. When a whipper-in rates a hound, and the hound does not mind him, he should, if possible, immediately take up such hound, and give him a severe flogging. But a hound should never be struck, unless he is conscious, at the same time, what it is for: when he is struck, the blow should be sharply inflicted.

If any hounds happen to be more riotous than the rest, in this case it may perhaps be allowable to give them a few cuts as they are about to leave the kennel.

When hounds are unsteady, every possible means should be adopted to make them otherwise. A hare, or a deer, put into the kennel amongst them may then be necessary.

Such hounds as are notorious offenders should also feel the lash and hear a rate, as they go to the cover; it may be a useful hint to them, and may prevent a severe flogging afterwards. A sensible whipper-in will wait his opportunity to single out his hound:—he will then hit him hard, and rate him well; whilst a foolish one will often abuse a dog he did not intend to hit; will ride full gallop into the midst of the hounds; will perhaps ride over some of the best of them, and put the whole pack into confusion.

*Have a care!* are words which seldom do any harm; as hounds when they are on the right scent, will not mind them. But a whipper-in should be careful how he *encourages* the hounds; which, im-

properly done, may very much injure the whole pack.

Some whippers-in will rate a hound, and then endeavour to flog him. A dog, after having been rated, will naturally avoid the whip. He should strike first, and rate afterwards.

"You will find it difficult (observes the intelligent Beckford) to keep your people in their proper places; I have been obliged to stop back myself to bring on hounds, which my servants had left behind. I cannot give you a greater proof how necessary it is that a whipper-in should bring home all his hounds, than by telling you that I have lost an old hound for ten days, and sent all the country over to inquire after him; and, at last, when I thought no more about him, in drawing a large cover in the country where he had been lost, he joined the pack: he was exceedingly emaciated, and it was a long time before he was recovered. How he subsisted all that time, I cannot imagine. When any of your hounds are missing, you should send the whipper-in back immediately to look for them—it will teach him to keep them more together."

A good whipper-in is of the greatest use in getting forward the tail hounds, which is a necessary part of fox hunting. He should also get forward himself at times, when the huntsman is not with the hounds; but the second whipper-in (who frequently is a young lad, ignorant of his business) on no account ought to encourage or rate a hound, but when he is quite certain it is right to do it; nor is he ever to get forward as long as a single hound remains behind.

*Halloo forward* is used too indiscriminately, and is for ever in the mouth of a whipper-in. If hounds are never used to that halloo till after a fox is found, they will fly to it. At other times, other halloos will answer the purpose of getting them on as well.

It frequently happens that the huntsman is jealous of the whipper-in: He looks on the whipper-in as a successor, and therefore does not very readily admit him into the kennel; yet, it is necessary he should go there; for he ought to be well acquainted with the hounds, who should know and follow him as well as the huntsman.

It is a great pleasure, when a hound challenges, to be certain he is right; it is a cruel disappointment to hear a rate immediately succeed to it, and the smacking of whips, instead of halloos of encourage-

ment. A few riotous and determined hounds will create much mischief in a pack. They should be taken out by themselves and severely chastised; and if they prove incorrigible, they should be consigned to the halter. The common saying, *evil communications corrupt good manners*, holds good with regard to hounds—they are easily corrupted. Separating riotous hounds from those that are steady, answers many good purposes. It not only prevents the latter from getting the blood they should not, but also prevents them from being overawed by the smacking of whips, which is too apt to obstruct drawing and going deep into cover.

"A couple of hounds, which I received from a neighbour last year (says Beckford) were hurtful to my pack. They had run with a pack of harriers; and, as I soon found, were never afterwards to be broken from hares. It was the beginning of the season, covers were thick, hares were plenty, and we seldom killed less than five or six in a morning. The pack at last got so much blood, that they would hunt them, as if they were designed to hunt nothing else. I parted with the two hounds; and the others, by proper management, are become as steady as they were before. You will remind me, perhaps, that they were draft hounds. It is true, they were so; but they were three or four years hunters; an age when they might be supposed to have known better. I advise you, unless a known good pack of hounds are to be disposed of, not to accept of old hounds. I mention this to encourage the breeding of hounds, and as the likeliest means of getting a handsome, good, and steady pack: though I give you this advice, I have accepted draft hounds myself, and some have been very good: but they were the gift of the friend mentioned by me in a former letter; and, unless you meet with such another, old hounds will not prove worthy of your acceptance: they never can be very good; and may bring vices along with them, to spoil your pack. If old hounds are unsteady, it may not be in your power to make them otherwise; and I can assure you from experience, that an unsteady old hound will give you more trouble than all your young ones. The latter will at least stop; but an obstinate old hound will frequently run mute, if he finds he can run no other way; besides, old hounds, that are unacquainted with your people, will not readily hunt for them as they ought; and such as were

steady in their own pack may become unsteady in yours. I once saw an extraordinary instance of this, when I kept harriers. Hunting one day on the Downs, a well known fox hound of a neighbouring gentleman came and joined in, and he both ran faster than we did, and skirted more, he broke every fault, and killed many hares. I saw this hound often in his own pack afterwards, where he was perfectly steady; and, though he constantly hunted in covers, where hares were in great plenty, I never remember to have seen him run one step after them."

It is shocking to hear hounds hallooed one minute and rated the next. Nothing offends a good sportsman so much, or is in itself so hurtful.—Whenever a pack is found to be very unsteady, there is much reason to believe, either that no care has been taken in entering the young hounds to make them steady, or else the men afterwards, by hallooing them on improperly, and to a wrong scent, have forced them to become so.

The first day of the season, it is advisable to take out the pack where there is the least riot, and where there is a tolerable certainty of finding; for, notwithstanding their steadiness at the end of the last season, long rest may have made them otherwise.

Beckford relates a remarkable instance of the steadiness of the hound.—“I must mention (says he) the extraordinary sagacity of a fox beagle, which once belonged to the Duke of Cumberland. I entered him at hare, to which he was immediately so steady that he would run nothing else. When a fox was found by the beagles, which sometimes happened, he would constantly come to the heels of the huntsman's horse; some years afterwards I hunted fox only, and though I parted with most of the others I kept *him*: he went out constantly with the pack; and, as hares were scarce in the country, he did no harm: the moment a fox was found he came to the horse's heels. This continued for some time, till catching view of a fox that was sinking, he ran in with the rest, and was well blooded.—He, from that time to the day of his death, was not only as steady a hound to fox as ever I knew, but became also our very best finder. I bred some buck hounds from him, and they are remarkable for never changing from the hunted deer.”

When hounds go out very late in the day, they should be immediately taken to the place where they are most likely to

find, which, generally speaking, is the cover, which hounds have been the least in. If the cover be large, only such parts of it should be drawn as a fox is likely to kennel in; it is useless to draw any other at a late hour. Besides, though it is always right to find as soon as you can, yet it is never so necessary as when the day is far advanced:—if you do not find soon, a long and tiresome day is generally the consequence. Where the cover is thick, you should draw as exactly as if you were trying for a hare; particularly, if it be furzy; for, when there is no drag, a fox, at a late hour, will lie till the hounds come close upon him.—Having drawn one cover, the huntsman should stay for his hounds, and take them along with him to another; as hounds will sometimes find a fox after the huntsman has left the cover. The whippers-in should not be sparing of their whips or voices on the occasion, and should come through the middle of the cover, to be certain that they leave no hounds behind them.

A huntsman will complain of hounds for staying behind in cover. It is a great fault, and makes the hound that possesses it of little value—a fault frequently occasioned by his own mismanagement. Having drawn one cover, he hurries away to another, and leaves the whippers-in to bring on the hounds after him; but the whipper-in is seldom less desirous of getting forward than the huntsman; and unless they come away easily, it is not often that he gives himself much trouble about them. Also, hounds that are left too long in their walks, will acquire this habit from hunting by themselves, and are not easily broken of it.

Hounds that lie idle are always out of wind, and are easily fatigued. The first day hounds go out after a hard frost much sport cannot be expected; on such occasions, therefore, more than the usual number of hounds should be taken out, and thrown into the largest cover; if any foxes are in the country, it is *there* they will be found.

A huntsman should determine within himself the number of hounds he intends to take out, as well as the number of young hounds that he can venture into the country where he is going to hunt, before he goes into the kennel to draft them. Different countries may require different hounds; some may require more hounds than others:—it is not an easy matter to draft hounds properly; nor can

any expedition be made in it without some method.

When the place of meeting and time are fixed, every huntsman should be as exact to them as possible. If the huntsman, without inconvenience, can begin drawing at the farthest cover down the wind, and so draw from cover to cover up the wind, it will have many advantages attending it: he will draw the same covers in half the time; the people cannot fail of being in their proper places; and there will be less difficulty in getting the hounds off; and as the fox will most likely run the covers that have been already drawn there is little probability of changing.

Huntsmen of penetration will observe where foxes like best to lie. Where there is a great tract of cover to draw, such observations are of great utility, and will save much time. Generally, foxes are partial to such as lie high, and are dry and thick at bottom; such also as lie out of the wind; and such as are on the sunny side of hills. The same cover where one fox has been found, if it has remained quiet any time, will most likely produce another.

It is to little purpose to draw hazel coppices at the time when nuts are gathered; furze covers, or two or three years' coppices, are then the only quiet places a fox can kennel in: they also are disturbed when pheasant shooting begins, and older covers are more likely. The season when foxes are most wild and strong is about Christmas: a huntsman then must lose no time in drawing; he should draw up the wind, unless the cover be very large, in which case, it may be better, perhaps, to cross it, giving the hounds a side wind, lest he should be obliged to turn down the wind at last:—in either case, he should draw as quietly as he can.

At this time, young coppices are quite bare: the most likely places, therefore, are four or five years' coppices, and such as are furzy at the bottom.

The best drawing hounds are shy of searching a cover when it is wet; and on such occasions the huntsman should ride into the likeliest part of it; and as there will most likely be no drag, the closer he draws the better:—huntsmen, by drawing in too great a hurry, frequently leave foxes behind them. Some huntsmen draw too quick; some too slow. The time of the day, the behaviour of the hounds, and the covers they are drawing will direct an

intelligent huntsman in the pace which he ought to go.

When a fox is found in a furze brake, he should never be hallooed till he has got quite clear of it;—when a fox is found in such a place, hounds are sure to go off well with him; and it must be owing either to bad scent, bad hounds, bad management, or bad luck, if they fail to kill him afterwards.

It is a common practice to rate as soon as a young hound challenges. No doubt, young hounds are often wrong; yet, since it is not impossible that they may sometimes be right, it would be better to wait a little, in order to ascertain whether any of the old ones will join, before any thing is said.

It is advisable not to hunt the small covers till you have well rattled the large ones; for, until the foxes are thinned and dispersed, where they are in plenty, it must be bad policy to drive others there to increase the number. If it be wished to thin the foxes, the hounds should be thrown into the same cover as long as as there is a fox to be found. If the hounds go off with the first fox that breaks, the cover is very little disturbed, and another fox will probably be found there again the next day; but where foxes are scarce, the same cover should never be drawn two days in succession.

When a fox slinks from his kennel, gets a great way before the hounds, and you are obliged to hunt after him with a bad scent—if you are in a country where foxes are in plenty, and you know where to find another, it will be advisable to call off, and try for a second. Unless a fox can be well pressed in the early part of the run, the hounds will not easily reach him; on the contrary, if he is at such a distance before them, as will enable him to regulate his pace, he will be very likely to tire out both horses and hounds:—hence one very essential reason for speed in the fox hunt. When the fox is a great way a-head, he will listen to the hounds, and will act accordingly—if the hounds are not able to blow him, the chase is sure to be very long, and will most likely end with the loss of the fox.

During the time that hounds are drawing for a fox, the sportsmen should place themselves in such a manner that he cannot go off unseen. Foxes will sometimes lie in sheep's scrapes on the side of hills, and in small bushes, and even in stubbles, where huntsmen seldom think of looking for them; yet, when they hear a hound,

they generally shift their quarters, and make for close cover. Gentlemen should take this necessary part of fox hunting on themselves, as the whippers-in have often business to occupy their attention.

Long drags in large covers give a great advantage to a fox, who, in such a case, generally sets off a long way before the hounds. This may be prevented by throwing the hounds in that part of the cover in which he is most likely to kennel: for want of this precaution, a fox will sometimes get so far the start of hounds that they are never able to hunt up to him afterwards. Also, when hounds first touch upon the drag, some huntsmen are so careless, that, while they are going on with it the wrong way themselves, a single hound finds the fox, and is not caught any more by the pack till he has lost him again.

Foxes are said to go down the wind to their kennel; but they do not always observe this rule.

There are some huntsmen, who, while their hounds are at fault, frequently make so much noise themselves that they can hear nothing else: they should always have an ear to a halloo.

When hounds approach a cover which it is intended they should draw, and dash away towards it, whippers-in generally ride after them to stop them. It is too late; they had better let them alone; it checks them in their drawing, and is of no kind of use: it will be soon enough to begin to rate, when they have found and hunt improper game. If a huntsman has his hounds under good command, and is attentive to them, they will not break off without his permission. Should he pass by the side of a cover which he does not intend to draw, his whippers-in must be in their proper places; but if he rides up a cover with them, unawed, uncontrolled—a cover where they have been used to find, they must be slack indeed if they do not dash into it. On this account, it is better not to approach the cover always in the same direction; hounds, by not being aware of what is going forward, will be less likely to break off, and will draw more quietly. Hounds are sometimes seen so flashy, that they will break away from the huntsman as soon as they see a cover; and yet the same hounds will stop, when they reach the cover side, and not go into it. Hounds should be very rigidly disciplined; and when they are not under good command, subject the sportsman to many inconveniences; and

he may at times be obliged to go out of his way, or draw a cover against his will:—it is not possible to do any thing with a pack of fox hounds, unless they are obedient. They should both love and fear the huntsman; they should fear him, but they should love him more. Dogs that are constantly with their masters acquire a wonderful degree of penetration, and much may be done through the medium of their affections.

Young foxes that have been much disturbed will lie at ground: the earth at such time should be stopped three or four hours before day, or no foxes will be found.

The first day a cover is hunted that is full of foxes, and you want blood, let them not be checked back into the cover, which is the usual practise at such times, but let some of them get off: if you do not, what with continual changing, and sometimes running the heel, it is probable none will be killed.

When hounds are encouraged to a scent, if they lose that scent, it is then an unsteady hound is for any kind of mischief.

Though a huntsman ought to be as silent as possible at going into a cover, he cannot be too noisy at coming out of it; and if at any time, he should turn back suddenly, he should give as much notice of it as he can to his hounds, or he will leave many of them behind him; and should he turn down the wind, he may see no more of them.

It is the judicious encouragement of hounds to hunt, when they cannot run; and the preventing them losing time by hunting too much when they might run, that distinguishes a good from a bad huntsman.—Hounds that have been well taught, will cast forward to a hedge of their own accord; but this excellence can never be acquired without discipline and education. To suffer a pack of fox hounds to hunt through a flock of sheep, when it is so easy to make a regular cast round them, is the height of absurdity—it is wilfully losing time to no purpose. It has been asserted that hounds should at no time be taken off their noses; but in answer to this, it may be justly remarked, that a fox hound which will not bear lifting, is not worth keeping.

Recurring to Beckford, he observes—“Though I like to see fox hounds cast wide and forward, and dislike to see them pick a cold scent through flocks of sheep to no purpose, yet I must beg leave to ob-

serve, that I dislike still more to see that unaccountable hurry, which huntsmen will sometimes put themselves into, the moment their hounds are at fault. Time ought always to be allowed them to make their own cast; and if a huntsman is judicious, he will take that opportunity to consider, what part he himself has next to act; but, instead of this, I have seen hounds hurried away the very instant they come to a fault, a wide cast made, and the hounds at last brought back again to the very place from whence they were so abruptly taken, and where, if the huntsman had had a minute's patience, they would have hit off the scent themselves. It is always great impertinence in a huntsman to pretend to make a cast himself before the hounds have made theirs'. Prudence should direct him to encourage, and, I may say, humour his hounds, in the cast they seem inclined to make, and either to stand still or trot round them, as circumstances may require.

"I have seen huntsmen make their cast on bad ground, when they might as easily have made it on good. I have seen them suffer their hounds to try in the midst of a flock of sheep, when there was a hedge near, where they might have been sure to take the scent; and I have seen a cast made with every hound at their horse's heels. When a hound tries for the scent, his nose is to the ground; when a huntsman makes a cast, his eye should be on his hounds; and when he sees them spread wide, and try as they ought, his cast may then be quick.

"When hounds are at fault, and the huntsman halloos them off the line of scent, the whippers-in cracking their whips and rating them after him, if he trots away with them, may they not think the business of the day is over?—Hounds never, in my opinion, (unless in particular cases, or when you go to a halloo) should be taken entirely off their noses; but when lifted, should be made to try as they go. Some huntsmen have a dull, stupid way of speaking to their hounds; at these times little should be said, and that should have both meaning and expression."

When a huntsman makes a cast, he should make it perfect one way before he tries another, as much time might otherwise be lost, in going backwards and forwards. Some huntsmen, when they have made a forward cast, come slowly back again—they should return as fast as they can.

If hounds come to a fault, and it is pro-

bable that the fox has been headed back, your forward cast should be short and quick, as the scent is then likely to be behind you: too obstinate a perseverance forward has been the loss of many foxes. In heathy countries, as we have already observed, if there are many roads, foxes will run them in dry weather; when hounds, therefore, overrun the scent, if the huntsman return to the first cross road, he will probably hit off the scent again.

In large covers, if there are many roads, when those are dry in bad scenting days, or after a thaw, when they carry, the huntsman should be near his hounds to help them, and hold them forward. Foxes will run the roads at these times, and hounds cannot always own the scent.

When hounds are at fault on a dry road, the huntsman should not turn back too soon; he should stop till he has ascertained that the fox has not gone on:—the hounds should try on both sides the road at once; if the huntsman perceive that they have tried on one side only, on his return, he should try the other.

If a fox runs the wind, when first found, and afterwards turns, he seldom turns again.

When a fox is pursued over a country, the scent being bad, and he a long way before the hounds, without ever having been pressed, if his point should be for strong earths that are open, or for large covers, where game is in plenty, it will perhaps be the best plan to take off the hounds at the first fault, as the fox will, under such circumstances, run the hounds out of scent; and indeed, if he should not, you will be very likely to change at the first cover you come into. But when a fox has been hard pressed, he should not, if possible, be given up.

If it be desirable to recover a hunted fox, and there is no longer any scent, a long cast to the first cover to which he seems to point is the only resource in such an emergency—the huntsman should get there as fast as he can, and, when there, the hounds should try as slowly and quietly as possible:—if hunting after him is hopeless, and a long cast does not succeed, it is time to give him up. In fact, when the scent is so bad that the hounds cannot hunt, the best way is, to give up the business for the day.—It is a fault in a huntsman to persevere in bad weather, when hounds cannot run, and when there is not a probability of killing a fox. There are some, however, who, after they have lost one fox for want of scent to hunt him,

will find another—this makes their hounds slack and sometimes vicious, and also disturbs the covers to no purpose.

When a huntsman has a perfect knowledge of his country, he possesses an eminent advantage—he can trot away and make a knowing cast, from having observed that nine foxes out of ten, with the wind in the same quarter, have constantly made for the same point or cover.

In a country, where there are large earths, a fox that knows the country, and tries one of them, seldom fails to try the rest. A huntsman may take advantage of this to get nearer his fox.

When a fox runs into a village, great caution is necessary: if he is halloo'd there, the huntsman should get forward as fast as he can. Foxes, when tired, will lie down any where, and are thus often lost. A wide cast is not the best to recover a tired fox with tired hounds—they should hunt him out, inch by inch, though they are ever so long about it, and for the reason just given, that he will lie down anywhere.

Where foxes are in plenty, a huntsman must take care that his hounds do not run the heel; since it sometimes happens that hounds can run the wrong way of the scent better than they can the right; for instance when one is up the wind, and the other down.

When the huntsman hears a halloo, and has five or six couple of hounds with him, the pack not running, let him get forward with those which he has; when they are on the scent, the others will soon join them.—He may lift his tail hounds and get them forward *after the rest*; it can do no hurt, but he must be cautious not to get them *before the rest*—it is always injurious, and foxes are sometimes lost by it.

Should a fox run his foil in cover, if all the hounds are suffered to hunt on the line of him, they will foil the ground, and tire themselves to little purpose. The huntsman, at such a time, should stop the tail hounds, and throw them in at head. Whilst hounds run straight, it cannot be of any use, as they will get on faster with the scent than they would without it.

When hounds are hunting a cold scent, and point towards a cover, a whipper-in should get forward to the opposite side of it: should the fox break before the hounds reach the cover, they should be stopped and get nearer to him.

If a fox persists in running in a strong

cover, lies down often behind the hounds, and they are slack in hunting him, the huntsman should get into the cover to them. Such a step may induce the fox to break, it may keep him off his foil, or may prevent the hounds from giving him up.

Slow huntsmen kill but few foxes; they are a check upon their hounds, which seldom kill a fox but with a high scent, when it is out of their power to prevent it. A perfect knowledge of the intricacies of hunting is chiefly of use to slow huntsmen and bad hounds, since they more often stand in need of it. Activity is the first requisite in a huntsman to a pack of fox-hounds, a lack of which no judgment can compensate or make amends for; but the most difficult part of a huntsman's business is the distinguishing betwixt different scents, and, knowing with any certainty, the scent of the hunted fox. Much speculation is here required—the length of time hounds remain at fault—difference of ground—change of weather—all which contribute to increase the difficulty, and require a nicety of judgment and a precision, much above the comprehension of most huntsmen.

When hounds are at fault, and cannot make it out themselves, the first cast should be quick—the scent is then good, nor are the hounds likely to go over it; as the scent gets worse, the cast should be slower, and be more cautiously made. This is an essential part of hunting, which few huntsmen attend to sufficiently:—with a good scent, the cast should be *quick*; with a bad scent, *slow*; and when the hounds are picking along a cold scent, *they should not be cast at all*.

If hounds are at fault, and staring about, trusting solely to their eyes and their ears, making a cast with them is not advisable. The likeliest place for them to find the scent is where they left it; and when the fault is evidently in the hounds, a forward cast is not likely to recover the scent.

When hounds are making a good and regular cast, trying for the scent as they go, the huntsman should not say a word to them; it cannot do any good, and may probably make them go over the scent.

If hounds come to a check, the huntsman should observe the tail hounds—they are least likely to overrun the scent, and he may see by them how far they brought it: in most packs there are some hounds that will shew the point of the fox; and if attended to, will direct the huntsman

in his cast. When such hounds follow unwillingly, the huntsman may be certain the pack are running without the scent.

When the huntsman casts his hounds, he ought to manifest some judgment, and not cast wide, without reason, since he will occupy more time about it. Huntsmen in general keep too forward in their casts, or, as a sailor would express it, *keep too long on one tack*. They should endeavour to hit off the scent by crossing the line of it, as two parallel lines can never meet.

When the huntsman goes to a halloo, he should be careful lest his hounds run the heel. "I once saw (says Beckford) this mistake made by a famous huntsman—after we had left the cover, which we had been drawing, a disturbed fox was seen to go into it; he was hallooed and we returned. The huntsman, who never inquired *where* the fox was seen, or on *which side* the cover he entered, threw his hounds in at random; and, as it happened, on the opposite side: they immediately took the heel of him, broke cover, and hunted the scent back to his very kennel."

Different countries require different casts; such huntsmen as have been used to a woodland and inclosed country, are apt to lose time in an open country, where wide casts are always necessary.

When it becomes necessary to cast round a flock of sheep, the whipper-in ought to drive them the other way, lest they should keep running on before.

A fox seldom goes over or under a gate, when he can avoid it.

Conceited huntsmen frequently spoil the sport. "Often have I seen them (says Beckford) when their hounds come to a check, turn directly back, on seeing hounds at head which they had no opinion of. They *supposed* the fox was gone another way: in which case Mr. Bayes's remark in the Rehearsal always occurs to me, '*that, if he should not, what then becomes of their suppose?*'—Better would it be to make a short cast forward first; they then might be *certain* that the hounds were wrong, and of course could make their own cast with greater confidence. The advantage, next to that of knowing where the fox is gone, is that of knowing with certainty where he is not.

"Most huntsmen like to have all their hounds turned after them, when they make a cast: I wonder not at them for it, but I am always sorry when I see it done; for, till I find a huntsman that is infallible, I shall continue to think the more my

hounds spread, the better; as long as they are within sight or hearing, it is sufficient. Many a time have I seen an obstinate hound hit off the scent, when an obstinate huntsman, by casting the wrong way, has done all in his power to prevent it. Two foxes I remember to have seen killed in one day by skirting hounds, whilst the huntsman was making his cast the contrary way."

If hounds are running in cover, and come into a road, and horses are on before, the huntsman should hold them quickly on beyond where the horses have been, trying the opposite side as he goes along. Should the horsemen have been long enough there to have headed back the fox, let him then try back.—When the fox has been headed back, the hounds ought to try back, but scarcely in any other case.

When hounds are divided into many parts, you had better go off with the first fox that breaks. The ground will soon get tainted, nor will hounds like a cover where they are often changing.

The heading a fox at first, if the cover be not a large one, is oftentimes of service to hounds, as he will not stop, and cannot go off unseen. When a fox has been hard run, the case may be different; and hounds that would have easily killed him out of cover, have sometimes left him in it.

If a fox has often been headed back on one side of the cover, and the huntsman knows there is not any person on the other to halloo him, the first fault his hounds come to, let him cast that way, lest the fox should be gone off; and if he is in the cover, he may still recover him.

A huntsman should on no account take out a lame hound. If any are tender footed, the huntsman, on being questioned, will generally remark, that they will not mind it when they are out—probably they may not—but how will they be the next day?—A hound not in condition to run, cannot be of much service to the pack, and taking him out at such a time may occasion a long confinement afterwards.

It need hardly be remarked, that a huntsman should not be allowed to hunt young hounds in couples. If necessary, it would be better if they were held in couples by the cover side till the fox is found.

The two principal things to which a huntsman has to attend are the keeping of his hounds *healthy* and *steady*. The

first may be accomplished by cleanliness and proper food; the latter, by putting, as seldom as possible, any unsteady ones amongst them.

When a fox has been lost, the huntsman would do well to examine himself, on his return home, and endeavour to ascertain in what he might have done better: by this means he may make the very losing of a fox of use to him.

Beckford remarks—"Old tyeing hounds, and a hare hunter turned fox hunter, are both as contrary to the true spirit of fox hunting, as any thing can possibly be. One is continually bringing the pack back again; the other as constantly does his best to prevent them getting forward. The natural prejudices of mankind are such, that a man seldom alters his style of hunting, let him pursue what game he may; besides, it may be constitutional, as he is himself slow or active, dull or lively, patient or impatient; it is for these reasons I object to a hare hunter for a pack of fox hounds, for the same ideas of hunting will most probably stick by him as long as he lives." Yet Beckford himself followed both hare and fox hunting at different periods; and yet little doubt can be entertained that he excelled in both; and although the chase of the fox and that of the hare, offer a striking contrast as to style and character, yet, we are of opinion (and we boast more than ordinary experience) that nothing is more easy than for a hare hunter to become a fox hunter; and he will perhaps become partial to the latter:—fox hunters are apt to entertain a mean opinion of the pursuit of the hare.

There is some variety in huntsmen. Sometimes a good kennel huntsman is met with; sometimes an active and judicious one in the field; and perhaps it is too much to expect these admirable qualities in the same person; it is certain they are seldom united in an eminent degree. Some are clever at finding a fox; others are better after he is found; whilst perfection in a huntsman, like perfection in any thing else, is scarcely ever to be met with: there are not only good, bad, and indifferent huntsmen; but there are perhaps a few others, who, being, as it were, of a different species, should be classed apart—we mean such as have real genius. Beckford says he would rather his first whipper-in possessed genius than his huntsman; and "one reason amongst others is, that he would have more opportunities of exercising it."

"The keeping hounds clean and healthy, and bringing them into the field in their fullest vigour, is the excellence of a good kennel huntsman; if, besides this, he makes his hounds both love and fear him; if he is active, and presses them on when the scent is good, always aiming to keep as near the fox as he can; if, when his hounds are at fault, he makes his cast with judgment, not casting the wrong way first, and blundering on the right at last, as many do; if, added to this, he is patient and persevering, never giving up the fox whilst there remains a chance of killing him, he then is a perfect huntsman."

In order to shew the superiority of fox hunting, he relates the following anecdote:—My hounds in running a fox (says he) crossed the great western road, where I met a gentleman travelling on horseback, a servant with a portmanteau, following him. He no sooner saw me, than he rode up to me, and with the greatest eagerness—"Sir, (says he) *are you after a fox?*"—When I told him we were, he immediately stuck spurs to his horse, took a monstrous leap, and never quitted us any more till the fox was killed. I suppose, had I said we were after a hare, my gentleman would have pursued his journey."

The true spirit of fox hunting is not to walk down a fox or starve him to death, but to keep close at him, and kill him as soon as you can. A fox hound may hunt too much; if tender nosed, and not over-hurried, he will always hunt enough; whilst the lightest bred hounds may be made to tye on the scent by improper encouragement. Slackness in the men occasions slackness in the hounds; and any person may perceive by the manner in which the hounds hunt, what kind of men they have been accustomed to.

All hounds go fast enough with a good scent; but it is the particular excellence of a fox hound, when rightly managed, to get on faster with an indifferent scent, than any other hound:—it is the business of a huntsman to encourage this; and here the principles of hare hunting will not apply to the pursuit of the fox. A hare hunter has been used to take his time; he has enjoyed a cold scent like a southern hound; and has sat patiently upon his horse to see his hounds hunt. "It is to be sure very pretty to see; and when you consider that the hare is all the time, perhaps within a few yards of you, and may leap up the next minute,

you are perfectly contented with what you are about ; but it is not so in fox hunting. Every minute you lose is precious, and increases your difficulties ; and, while you are standing still, the fox is running miles.—It is a satisfaction to a hare hunter to be told where the game was seen, though a long while before ; but it is melancholy news to a fox hunter, whose game is not likely to stop.”

When hounds flag from frequent changes and a long day, it is necessary for a huntsman to animate them as much as he can ; he must keep them forward and press them on ; for it is not likely, in this case, that they should overrun the scent : at those times, the whole work is generally done by a few hounds, and he should keep close to them. If they come to a long fault, the business is over.

The many chances in favour of the fox in fox hunting, such as the frequent changing, the heading of the fox, his being coursed by sheep dogs, long faults, cold hunting, and the dying away of the scent, make it necessary to keep always as near the fox as possible :—this should be the first and invariable principle of fox hunting.

Nothing is more essential in fox hunting than the huntsman knowing the country he is to hunt. Foxes are not capricious creatures, but know very well what they are about ; are quick in determining, and resolute in perseverance. They generally have a point to go to ; and, though headed and turned directly from it, seldom fail to make it good at the last ; *this*, therefore, is a great help to a huntsman of discernment.

Huntsmen should not be suffered to encourage their hounds too much on bad scenting days, particularly in covers, where there is much riot.—*Hark ! hark !* which injudicious huntsmen are so apt to use upon every occasion, must often do mischief, and cannot do good ; whilst hounds are near together, they will sooner get to the hound that challenges without that noise than with it. If it be a right scent, they will be ready enough to join ; and if it be a wrong one, provided the huntsman lets them alone, they will soon leave it :—injudicious encouragement on a bad day, might make them run something or other, right or wrong.

There is no fault so bad in the hound as that of running false ; it should never be forgiven : such as are not stout, that are stiff nosed, or that have other faults, may at times do good, and at worst may

do no harm ; whilst such as run false, most probably will spoil your sport.

A huntsman ought to know how to marshal every hound in the pack, giving to each his proper rank and precedence ; for without this knowledge it is not possible he can make a large draft as he ought. There are in many packs some hounds that assist but little in killing the fox, and it is the judicious drafting of such hounds that shews a good huntsman.

Fox hounds to hunt well, should be well in blood. “ When hounds are out of blood, there is a kind of evil genius attending all they do ; and though they may seem to hunt as well as ever, they do not get forward, whilst a pack of fox hounds well in blood, like troops flushed with conquest, are not easily withstood. What we call ill luck, day after day, when hounds kill no foxes, may frequently, I think, be traced to another cause, viz. *their being out of blood* ; nor can there be any other reason assigned why hounds, which we know to be good, should remain so long as they sometimes do without killing a fox.—Large packs are least subject to this inconvenience ; hounds that are fresh and in high spirits, least feel the want of blood. The smallest packs, therefore, should be able to leave at least ten or twelve couple of hounds behind them, to be fresh against the next hunting day. If your hounds are much out of blood, give them rest : take this opportunity to hunt with other hounds, to see how they are managed, to observe what stallion hounds they have, and to judge yourself whether they are such as it is fit to breed from or not.”

“ When hounds are out of blood, give them every advantage : go out early, choose a good quiet morning ; and throw off your hounds where you are likely to find, and are least likely to change : if it is a small cover or furze brake, and you can keep the fox in, it is right to do it ; for the sooner that you kill him when you are in want of blood the better.”

“ When hounds are in want of blood, and you get a fox into a small cover, it must be your own fault if you do not kill him there : place your people properly and he cannot get off again. You will hear perhaps that it is impossible to head back a fox. No animal is so shy, consequently no animal is so easily headed back by those who understand it. When it is your intention to check a fox, your people must keep at a little distance from

the cover side, nor should they be sparing of their voices; for, since you cannot keep him in, if he be determined to come out, prevent him, if you can, from being so inclined.—All kind of mobbing is advisable, when hounds are out of blood; and you may keep the fox in cover, or let him out, as you think the hounds will manage him best.

“Though I am a great advocate for blood, so necessary, in my judgment, to a pack of fox hounds, yet I by no means approve of it to the extent to which it has sometimes been carried. I have known three young foxes chopped in a furze brake in one day without any sport. A wanton destruction of foxes, and scarcely answering the purposes of blood, since that blood does hounds most good, that is most dearly earned. Such sportsmen richly deserve blank days; and, without doubt, they often meet with them. Mobbing a fox, indeed, is only allowable when hounds are not likely to be a match for him without it. One would almost be inclined to think that blood was as necessary to the men, as to the hounds, since the best chase is flat unless you kill the fox. When you ask a fox hunter what sport he has had, and he replies it was *good*; I think the next question generally is, *did your hounds kill*?—If he says they *did not*, the conversation ends; but if, on the contrary, he tells you that they did, you then ask a hundred questions, and seldom are satisfied till he has told you every particular of the chase.

“When there is snow on the ground, foxes will lie at earth. Should your hounds at that time be in want of blood, it will be easy to dig one to turn out before them when the weather breaks; but I seem to have forgotten a new doctrine which I lately heard, that blood is not necessary to a pack of fox hounds. If you also should have taken up that opinion, I have also to wish that the goodness of your hounds may prevent you from the changing of it again, or from knowing the truth of it.”

Perfectly aware as we are that the doctrine promulgated by Beckford in regard to the necessity of blood for a pack of fox hounds, is the general opinion, yet it is necessary to state that there are those who entertain different notions on the subject. From the last paragraph it clearly appears that, in the time of Beckford, dissentients were to be found; and if our information be correct, the late celebrated Mr. Meynell, to whom fox hunting owes

so much, and who is supposed to have possessed a much more than ordinary share of knowledge on the subject, was of opinion that blood was by no means indispensable to the perfection of the fox hound; and, beyond all doubt, some very cogent reasons may be brought in favour of the latter opinion: that, however, which appears the most prominent is the circumstance of the stag hound being very seldom allowed blood, and yet his eagerness in the pursuit seems not at all abated.—The king's stag hounds are never suffered to pull down a deer where it is possible to prevent it; the same remark will equally apply to those of the Earl of Derby; and indeed to stag hounds in general. There are many packs of harriers which are scarcely ever allowed a hare, and yet it does not appear to slack their mettle. Ferrets, after they have killed rats, are never allowed to eat them, and yet they continue to pursue them with the same degree of fierceness. So that, under all the circumstances of the case, the question as to the necessity of blood for fox-hounds does not seem absolutely determined. However, it is the general opinion, as before observed, and one to which we cannot help subscribing.

“No good country (says Beckford) should be hunted after February, nor should there be any hunting at all after March. Spring hunting is sad destruction of foxes; in one week you may destroy as many as would have shewn you sport for a whole season. We killed a bitch fox one morning, with seven young ones, which were all alive: I can assure you we missed them much next year, and had many blank days, which we need not have had but through our own fault. I should tell you that this notable feat was performed literally on the first of April. If you will hunt late in the season, you should at least leave your terriers behind you.”

It is the modern custom, however, to hunt later than March; and some go so far as to kill a May fox. Beckford's position is, nevertheless, perfectly correct. Dog foxes are more difficult to kill towards spring than any other time; but the reverse is the case with bitch foxes; those therefore who are determined to continue fox hunting till a late period of the season should, if possible, ascertain, at the commencement of the run, whether it is a dog or bitch fox which is before them; and call off, if it happen to be the latter.

Foxes' heads, which are so pompously exposed to view are often prejudicial to sport. How many foxes are wantonly destroyed, without the least service to the hounds, or sport to the master, that the huntsman may say he has killed so many brace. Beckford relates a case in point:—"I remember to have seen a pack of hounds (says he) kill three foxes in one day; and though the last ran to ground, and the hounds had killed two before, and therefore could not be supposed to be in want of blood, the fox was dug out, and killed upon the earth."

All countries are not equally favourable to hounds; and the same hounds that behave well in one will sometimes appear to behave indifferently in another—a good scenting country must of course be always the most favourable; and those countries which stand pre-eminent in this respect, such as the neighbourhood of Melton Mowbray, consist chiefly of pasture land.

In regard to bag foxes, hounds should be as little used to them as possible:—the scent of them is stronger than that of other foxes; and is therefore apt to make hounds idle; besides, in the manner in which they are frequently turned out, it makes hounds very wild. They seldom fail to know what is going forward before the fox is turned out; and if often used to bag foxes will become riotous enough to run any thing. A fox that has been confined long in a small place, and carried out afterwards some miles in a sack, his own ordure hanging about him must needs stink extravagantly; to which may be added, he is most probably weakened for want of his natural food and usual exercise; his spirit broken by despair, and his limbs stiffened by confinement; he then is hurried out in open ground, without any point to go to; he runs down the wind, it is true; but he is so much at a loss all the while, that he loses a good deal of time in not knowing what to do; while the hounds, who have little occasion to hunt, pursue as closely as if they were tied to him. If, however, it be necessary to turn out a bag fox, he should be turned into a small cover, and the hounds should be laid on as quietly as possible—in order that they may suppose they found him.

As bag foxes always run down the wind, those who turn them out may therefore choose what country they shall run. Foxes that are found do not follow this rule universally: strong earths and large covers are great inducements to

them, and it is no inconsiderable wind that will keep them from them.

"If you breed up cubs (says Beckford) you will find a fox court necessary: they should be kept there till they are large enough to take care of themselves. It ought to be open at the top and walled in: I need not tell you that it must be every way well secured, and particularly the floor of it, which must be either bricked or paved. A few boards fitted to the corners will also be of use to shelter and hide them. Foxes ought to be kept very clean, and have plenty of fresh water; birds and rabbits are the best food: horse flesh might give them the mange."

"I have kept foxes too long (he continues): I also have turned them out too young. The safest way, I believe, will be to avoid either extreme. When cubs are bred in an earth near you, if you add two or three to the number, it is not improbable that the old fox will take care of them: of this you may be certain, that, if they live, they will be good foxes; for the others will shew them the country. Those which you turn into an earth should be regularly fed. If they are once neglected, it is probable they will forsake the place, wander away, and die for want of food. When the cubs leave the earth, (which they may soon do) your gamekeeper should throw food for them in parts of the cover where it may be most easy for them to find it; and, when he knows their haunt, he should continue to feed them there. Nothing destroys so much the breed of foxes as buying them to turn out, unless care is taken of them afterwards."

When a country is extensive and not equally good, it may be advisable to send some cubs from one part of it to the other. A fox court, therefore, is of great use; it should be airy, or the cubs should not be kept long in it. If the cubs are large they may be turned out immediately: a large earth will be the best for the purpose, where they can be regularly fed. Where rabbits are plentiful, nature will soon teach them how to catch the young ones; and, till that period of abundance arrives, it will be necessary to provide food for them. Where game is scarce, wet weather will be most favourable to them; they can then live on beetles, chaffers, worms, &c. of which they will find great plenty. The morning is the best time to turn them out: if turned out in the evening they will be more likely to ramble; but, if turned out

early, and fed on the earth, there is little doubt of their remaining. They should be turned into large covers and strong earths; from small earths they are more likely to be stolen; and from small covers, they are more apt to wander. Gamekeepers, at this time of the year, having little else to do, may feed and take care of them.

With respect to digging of foxes that have been run to earth, the hole is generally followed, except where the earth is large, and the terriers have fixed him in an angle of it—the more expeditious method then is to sink a pit as near to him as possible. By listening above ground, that is, by placing your ear close to the ground, a tolerably correct opinion may be formed of the situation of the fox, from the noise of the terriers. A terrier should always be kept at the fox, otherwise he may move, and in loose ground may dig himself further in. In digging, room enough should be kept, and care should be taken not to throw the earth where there may afterwards be occasion to remove it. In following the hole, the surest way not to lose it, is to keep below it. All the holes on the surface should be stopped, lest the fox should bolt unseen.

If hounds are in want of blood, and they have had a long run, it is the best way without doubt to kill the fox on the earth; but if they have not run long, and the fox is easy to be dug, and the cover such a one as they are not likely to change in, it does the hounds more good to turn him out, and let them work for him. But before this is done, if there be any other earths in the cover, they should be stopped, lest the fox should go to earth again.

But, before the operation of digging is commenced, the huntsman should try all round, and be perfectly satisfied that the fox has not gone on: “for want of this precaution (says Beckford) I dug three hours to a terrier that lay all the time at a rabbit.”

A fox will sometimes go over an earth, and will not go into it; he will sometimes go in and will not remain—he may find it too hot, or not like the company he meets with there—a fox has most likely good reasons for all he does, though we are not acquainted with them.

Huntsmen, when they get near a fox, will sometimes put a hound in to draw him. This is, however, a cruel operation, and seldom answers any other purpose than to procure the dog a very severe

biting, the fox's head generally being towards him; besides, a few minutes' digging will make it unnecessary. If you let the fox first seize the handle of your whip, the hound will more readily draw him.

If foxes are bred in an earth which is deemed unsafe, they had better be stunk out; that, or any disturbance at the mouth of the hole, will make the old one carry them off to another place.

Foxes, when they are much disturbed in open countries, will lie at earth. If any difficulty occur in finding, stinking the earths will sometimes produce them again.

Stinking earths may be practised in the following manner:—Three pounds of sulphur and one pound of assafoetida should be boiled up together; matches should then be made of brown paper and lighted in the holes, which are afterwards stopped very close. Earths that are not used by badgers may be stopped early, which will answer the same purpose; but where badgers frequent, it would be useless, as they would open them again.

If terriers be required to run with the pack, large ones at times are useful; but in an earth they do but little good, as they cannot always get up to the fox.

A young terrier should not be entered at a badger (which was formerly much practised); as young terriers have not the art of shifting like old ones; and, if they are good for any thing, most probably will go up boldly to him at once, and thus get themselves terribly bitten; for this reason they should be entered at young foxes where it is convenient.

Besides the digging of foxes, by which method many young ones are taken and old ones destroyed, traps, &c. are too often fatal to them. Farmers for their lambs (which by the bye are very rarely killed by foxes) gentlemen for their game, and old women for their poultry, are their inveterate enemies.

“To those who may think the danger that attends hunting (says Beckford) a great objection to the pursuit of it, I must beg leave to observe, that the accidents which are occasioned by it are very few. I will venture to say that more bad accidents happen to shooters in one year than to those who follow hounds in seven. You will remind me perhaps of the death of F—h, and the fall of D—t; but do accidents never happen on the road? The most famous huntsman, and the boldest rider of his time, after having hunted a

pack of hounds for several years unhurt, lost his life at last by a fall from his horse, as he was returning home. A surgeon of my acquaintance has assured me, that in thirty years' practice, in a sporting country, he had not once an opportunity of setting a bone for a sportsman, though ten packs of hounds were kept in the neighbourhood. This gentleman surely must have been much out of luck, or hunting cannot be so dangerous as it is thought. Besides, they are all timid animals which we pursue, nor is there any danger in attacking them: They are not like the furious beast of the *Gevaudun*, which, as the French author informs us, *twenty thousand French Chasseurs went out in vain to kill!*"

It must be allowed that Beckford's notions of hunting are completely orthodox; his book on the subject contains much sound reasoning, as well as a great variety of judicious remarks. In his time, fox hunting had been much improved; the hound had been rendered more fleet, and the business altogether was better understood than it had been previously to this period: fox hunting has since been cultivated as a science, and the hound used for the purpose of pursuit rendered still more swift. Formerly, a fox chase continued, generally, for four hours; half that period is at present considered a long run; and, with some of our modern crack packs, the business is very often concluded in half an hour.

For the consideration and description of the dog best calculated for the pursuit of the fox, the reader is referred to the article "HOUND."

We shall now sketch a few of those extraordinary runs which have at various times occurred in the pursuit of the fox, and which have rendered fox hunting so celebrated. Some of them have appeared before in print: but they seem, nevertheless, indispensable to the completion of this highly interesting subject.

"I set out (says Beckford) one day last winter from the kennel at half past seven, and returned home a quarter before eight at night, the hounds running hard the greater part of the time. The huntsman killed one horse and tired another; and the hounds did not recover it for more than a week: we took them off at last when they were running with a better scent than they had had all the day. I remember after it was quite dark to have heard a better view halloo from an owl, than I ever heard from a sports-

man in my life, though I hope that I shall never hear such another!"

On the 7th December, 1800, the Duke of Rutland's hounds, after pressing a fox very hard, ran him into the town of Sleaford, where for a long time he dodged about the yards and buildings, and at length went down the open market-place, pursued by a number of different dogs, from which he escaped through the end of the town. So soon as the hounds could be disengaged from the throng of the people, which the circumstance had brought together, they were cast forward and again got upon the scent, and hunted their fox in capital style; but were finally beat after an admirable run of two hours.

In January, 1738, the Duke of Richmond's fox-hounds found at a quarter before eight, and killed at ten minutes before six, after ten hours constant running. Many of the gentlemen tired three horses each. Only eleven couple and a half of the hounds were in at the death.

Upon the 19th of February, 1783, a fox was unkennelled near Boroughbridge, Yorkshire, at twenty-seven minutes past nine, and except half an hour occupied in bolting him from a rabbit burrow, the hounds had a continued run until fourteen minutes past five o'clock in the afternoon, when they killed. During the space of nearly eight hours hard running, several horses died in the field, and many others were so seriously injured that they never perfectly recovered afterwards.

In 1793, Sir Charles Danver's hounds found a leash of foxes in one cover: the hounds divided into three parts; each had a very severe run, and each killed their fox.

In 1795, a pack of fox-hounds in Cambridgeshire, after running a fox nearly an hour, found a brace of fresh foxes; the hounds divided, *six couple and a half* went away with one of them, and killed at Weathersfield. One couple of hounds pursued the other, and killed him at Thurlow Park Gate. *Fifteen couple and a half* stuck to their hunted fox, and killed at the bottom of Gogmagog Hill, after a chase of one hour and three quarters without a check, and in which time they were supposed to have run nearly thirty miles.

In drawing a strong cover, a young bitch gave tongue very freely, whilst none of the other hounds challenged:—the whipper-in rated to no purpose, and the huntsman insisted she was wrong; the whip was applied with great severity, in

which the lash accidentally struck one of her eyes out of the socket: notwithstanding which, the bitch again took the scent, and proved herself right; for a fox had stole away, and she broke after him unheeded and alone; however, after much delay and cold hunting, the pack did at length hit off the chase. At some distance, a farmer informed the sportsmen, that they were far behind their fox, for that a single hound, very bloody about the head, had passed a field off from him, and was running breast high, and that there was little chance of their getting up to him. The pack, from her coming to a check, did at length get up; and after some cold hunting, the bitch again hit off the scent. The fox was killed, after a long and severe run, and the eye of the bitch, which had hung pendant during the chase, was taken off by a pair of scissors.

The Duke of Northumberland's hounds, in the year 1796, ran a fox into a very large furze cover near Alnwick, called Bunker's Hill, where he was lost in an earth, with which no one was acquainted. Upon the hounds returning to the kennel two couple and a half of the best were missing, and not returning that night, it was thought they had found a fox and gone off with him. Men were sent out in search of them to all the earths and crags for many miles round, but no tidings could be gained. The cover where the fox had been lost was then carefully searched, and the earth discovered: in digging about two yards deep, *one* hound was found; several yards further *three* more, wedged together in the ground; and a little further on, the *fifth* hound was dug up—all dead.

On Monday the 14th of March, 1825, the Cheshire fox-hounds (under the direction of Sir Harry Mainwaring) met at Shipbrook Bridge, Cheshire, at half past ten o'clock; and found in Moulton Wood, opposite Winstead Salt Works. The fox went away in gallant style: he faced the open country, and took the direction for Harford Bridge, and then leaning to the right, made for Bostock Park, crossed it, and made over the fields for the river Dane, along the banks of which he proceeded till he approached Leftwich, took the water, leaving Shipbrook Bridge considerably to the right. He then made away in the direction of Holford Moss, passing near to Northwich in his progress. The hounds had pressed him very hard—he was repeatedly viewed, and it was supposed death could be at no

distance. He reached a plantation near Holford Moss, where it was supposed he must surrender, after a brilliant run of three quarters of an hour. However, renard was not disposed to give up on such terms; he left the plantation, and making for Winnington Wood, crossed the main road (between Manchester and Northwich) and was seen to enter Winnington Wood very much distressed. The hounds came to a trifling check on some fallows on the opposite side of Winnington Wood, the fox gained some distance, and ran along the river side, leaving Mr. Townshend's (of Wichand) to the left, and, running in a line for Marbury for some time, came back nearly in the same line for Winnington Wood. On the fox approaching Winnington Wood the second time, he did not enter, owing perhaps to his being unable to keep it on the first occasion; but leaving it to the right, crossed a considerable extent of country and reached Tabley; crossed Tabley Park, leaving the turnpike to the right, and onwards to Mere; he crossed the turnpike road again near the toll bar at Mere, to Mere Moss, and run over the Moss to Tatton Park; crossed it and also the pleasure grounds down to the Mere, along the Mobberly side of the park; but on reaching the water, he turned short up to Knutsford town end; here he appeared to be surrounded by the hounds, and death seemed inevitable: he, however, jumped, or by some means, scrambled over a wall six feet high, and went away again, leaving Knutsford Race Course to the left, in a line for Holford Moss:—he was viewed and headed back: he entered Tatton Park a second time, and proceeding along the Rothern side, turned from the lodge in the direction of Rothern, into a plantation on the Mobberly side of it. Here he was viewed by one of the whippers-in. He left the plantation, and was headed back into it from under Knutsford, and, on being driven through, made away in the direction of Spring Woods, when the pursuit was given up, after nearly six hours' running.

**FOYLING OR FOILING.** The footing of a stag upon the grass where it is scarcely discernible.

**FRANK CHASE.** Is the liberty of free chase in a circuit adjoining to a forest, by which all men, though they have land of their own within that compass, are forbidden to cut down wood, &c. without the view of the forester.

**FRAY.** A deer is said to fray his

head, when he rubs it against a tree to renew it, or cause the pills of his new horns to come off. **FREAM.** A term used of a boar, that makes a noise at rutting time.

**FREE WARREN.** A Free Warren is totally distinct from Forest, Chase, Park, Manor, or Warren; it is a franchise derived originally from the crown; and the person having a grant of free warren over certain lands, possesses the sole right of pursuing, taking, and killing game of every description within its limits; although there may be no one acre of land his own property through the whole district where he possesses this right. There are instances where a variety of circumstances render manorial rights and privileges so complex, and seemingly indefinite, as to produce litigation without personal enmity, but merely that the right shall be legally ascertained. It appears that where manor lands are situate in, and surrounded by, a free warren, the owner of such lands may kill game within his own manor, but he cannot introduce even a qualified person to kill game there also, without the consent of the owner or possessor of the privilege of free warren over the whole; if so, the person introduced killing game, will be liable to an action for trespass.

A curious cause came on to be tried before a jury at the summer assizes of the year 1802, held at Abingdon, for the county of Berks, wherein John Westbrook, gent. of the parish of Bray, (situate in Windsor Forest) was plaintiff, and one of his majesty's gamekeepers defendant. The action was brought to try the right of the gamekeeper to kill game within the *inclosed grounds* of the plaintiff, situate in, and surrounded by, the wastes, commons, and within the boundaries of the said forest. When, without adverting to the laws relative to the forests only (with which the question was totally unconnected) the court held it good that the king, possessing a free warren over the whole, possessed likewise the privilege of appointing a keeper to kill game upon any, and within every, part of the said free warren, without the least exception as to inclosed lands, the property of others; when the jury instantly found for the defendant.

A similar case occurred on the 12th of July of the same year, Henry Brown, Esq. of North Mimms, plaintiff; and Thomas Greenwood, the younger, defendant. The action was brought for a trespass committed by the defendant, in shooting game within the free warren belonging to the plaintiff, who was lord of the manor of North Mimms, and entitled to free warren through the whole manor. It appeared that the land on which the trespass was committed and the game killed, by the defendant, was not, in point of fact, the land of the plaintiff; but, on the contrary, belonged to Justinian Casamajor, Esq. However, as it was proved to be within the manor of North Mimms, and the right of free warren extending over the whole of the manor, the jury, after considering the circumstances of the case, gave a verdict of ten pounds, with costs.

**FRET.** Another name for the gripes or colic in horses.

**FROG,** in the anatomy of the horse, a part of the foot, the form and essential purposes of which, Mr. COLEMAN, professor at the Veterinary College, describes in the following terms:—

## F R O G

The natural frog of the horse, says he, is placed in the centre of the sole, externally convex, and of a wedge-like form, pointed towards the toe, but expanded as it advances to the heels. In the centre of the broad part, there is a fissure or separation. The frog is connected internally with another frog, of a similar figure, but different in structure. The external frog is composed of soft elastic horn, and totally insensible. The internal frog has sensation, and is much more elastic than the horny frog; and at the extremity of the heels is connected with two elastic substances called cartilages. The toe of the sensible frog is united to the coffin-bone; but more than nine tenths of both frogs are behind the coffin-bone. The toe of the sensible and horny frogs, from their connection with the coffin-bone, are fixed points, and have no motion; but the heels of the frogs being placed posterior to the coffin-bone, and in contact with moveable, elastic, and not fixed or resisting, substances, a very considerable lever is formed, and whenever the horny frog comes in contact with the ground, it first ascends, and then descends. The pressure of the ground also expands the horny frog, and the sensible frog expands the cartilages, and at the heels and quarters, immediately below the hair, totally governs the direction of the future growth of the crust.

This ascent of the frog not only, by its wedge-like form, preserves the heels and quarters from contraction, but affords to the horse an elastic spring, and prevents the animal from slipping whenever it embraces the ground. Without any anatomical enquiry into its internal structure and union with other parts, the shape and convexity of the horny frog clearly demonstrates that it was formed to come into contact with the ground; and the more I investigate this subject, the more I am convinced that the use of the frog is to prevent the horse from slipping, to preserve the cartilages and hoof expanded, and, by its motion, to act as an elastic spring to the animal.

Mr. Coleman contends, that Mr. St. Bel, and many others, who suppose that the use of the frog is merely *to serve as a cushion*, or guard, to the tendon of the flexor muscle of the foot, and who, on that account, were disposed rather to *raise the frog from the ground* by a *thick-heeled* shoe, have been in an error. On the contrary, he maintains it to be a law of nature, that, unless the frog performs its functions, by being allowed to press the ground, it must become diseased. Accordingly, the practise of shoeing very much depends on the functions of the frog being understood.

If the opinions here advanced respecting its uses be well founded, then it must follow, that paring the frog, and raising it from the ground, annihilates its functions, and ultimately, if not immediately, produces disease; and that exposing the frog to pressure is the only proper method to keep it in health. Moreover, it has from experience been ascertained, that, unless the frog sustain an uniform pressure when at rest, the heels as well as the frog contract; but if that organ be in close contact with the ground, then it spreads and is free from thrushes and canker, and operates as a wedge to keep open the heels of the hoof.

Granite and other hard substances give no pain to a frog exposed

## F R O G

to constant pressure in the stable ; but, when above the pavement, it generally becomes contracted, and the sensible frog inflamed, and then one stroke from a projecting stone will produce pain, perhaps lameness, while perpetual perpendicular pressure is attended with salutary effects.

When the hoof contracts, the frog must also become contracted, and inflammation and a suppuration follows, called a *thrush*. No contraction, however, takes place where the frog is made to receive constant pressure, as the standing perpetually on that wedge increases its growth, presses upward the sensible frog, and expands the cartilages of the hoof. And as the first shoot of the crust at the coronet is very thin, the direction of its fibres will be altogether regulated by the width of the cartilages immediately below the hair at the quarters and heels, and the cartilages will be always more or less expanded, and the hoof more or less circular, as the frog has more or less pressure.

On that principle, continues Mr. Coleman, I long since recommended a shoe with *thin heels* as the best formed shoe to bring the frog on the same level ; and with great truth I can assert, that, although in some instances, from a sudden misapplication of the thin-heeled shoe to improper feet, I have seen the tendons affected, yet, from all the experience I have since had, and from what I have seen or heard of the practise of others, I know of no instance where the frog, from constant pressure, did not expand and receive great benefit.

Where the frog is in a morbid state, and unnaturally deprived of perpendicular pressure, it is seldom safe to lower the heels at once, so as to make the frog on a level with the shoe ; and, in many cases, it is not possible with any shoes, or even without shoes, to give the frog pressure on smooth surfaces ; much less is it practicable for the frog to rest on the ground when shod with common thick-heeled shoes. In the stable, therefore, while at rest, the frog is generally raised above the shoe ; and as pressure is essential to its health, particularly when the hoof is exposed to heat, it appeared to me of great importance, in all cases where the heels of the shoe and the frog cannot with safety be made on the same level, to apply an artificial frog, to fit and give any degree of pressure, in the stable, to the natural frog, with any shoes. While the horse is in motion, and the hoof exposed to unequal surfaces, the artificial frog should be removed, as the natural frog, out of the stable, will receive frequent pressure with any shoes ; but that is of short duration, when compared to the length of time the horse remains at rest, and the frog raised from the ground.

Artificial pressure is most particularly wanted when the heat of the stable operates powerfully to contract the hoof. In all cases, therefore, where the pavement of the stable does not touch the natural frog, an artificial frog is necessary to resist contraction of the hoof, thrushes and canker. Sand-cracks, also, very generally arise from a contracted hoof, and may be prevented by the artificial frog.

If the frog does not absolutely rest on the pavement, whatever shoes are employed, the hoof in the stable will be as much disposed

to contract as if the frog was raised any greater distance. I wish this fact to be well considered ; for it has been supposed that shoes with a flat seat, without pressure to the frog, will prevent contraction. But I am fully convinced, that neither thick nor thin heeled shoes, where the frog is raised above pressure, and exposed to the heat of the stable, can prevent contraction or its effects ; and, where the frog receives that pressure, the heels cannot contract even with the most common shoes. For very obvious mechanical reasons, a wedge in the centre of the heels, aided by the pressure from below, must be best calculated to preserve them expanded, or, when the heels are contracted, to force them open. The heat of the stable in all cases tends to contraction of the hoof ; but, with common shoes, there is no pressure on the wedge, or other cause to counteract that tendency. The artificial frog, which is intended to cover and give any degree of pressure to the natural frog only, is made of iron. In order to fit the natural frog, it is requisite to ascertain its width, the length of the foot, and the distance between the lower surface of the shoe and the frog. But if the artificial frog be too long, the toe, which is flat and thin, may be shortened ; and if the heels of the shoe are higher than the artificial frog, nothing more is requisite than to introduce a quantity of tow between the natural and artificial frog, so as to raise it equal or above the level of the shoe. I have ascertained by experience, that no inconvenience takes place by raising the artificial frog even one quarter of an inch above the shoe ; but, in ordinary cases, it should not project more than one sixth of an inch above the surface of the shoe. It may, however, be imagined, that so much perpendicular pressure to the frog would retard rather than increase its growth : but the very reverse is the fact ; for, as the frog, when long elevated above the ground, is very generally contracted, this unnatural lateral pressure excites inflammation of the sensible frog, and deprives, in a great degree, the blood-vessels of the power of secreting horn. When the horny frog is exposed to perpendicular pressure, it gives health, and not disease, to the sensible frog. The blood-vessels secrete their due proportion of elastic horn, and then the cavity of the frog is preserved, expanded, and fully equal to contain the sensible frog, without the smallest degree of lateral pressure.

It therefore follows, that perpendicular pressure increases the bulk of the frog ; while its absence from the ground produces contraction, and lessens its growth.

**FROTH.** A horse displaying a profusion of froth when champing upon the bit, either in action upon the road, or in the field with hounds, may be a distinguishing sign of both good spirit and sound bottom. It is also no inferior criterion of health, and may, in general, be considered truly indicative of condition : few horses of this description flag upon a journey, or tire in the field.

**FRUSH OR THRUSH.** See **THRUSH**.

**FULMART,** a **POLECAT**, which see.

**FUMETS, OR FEWMETS.** The dung of a hart.

**FUMIGATION** is a most useful process in all cases where the diseases of horses particularly affect the head. In recent colds, obstinate coughs, glandular tumefactions under the jaws, strangles, inflammation of the lungs, low fevers, and even in dullness, over-fatigue, or when a horse is off his appetite, and refuses food, it is very frequently of perceptible utility. Horses may be fumigated by boiling rose-

mary, lavender, marshmallow leaves, and camomile flowers, in a few quarts of water over the fire for a quarter of an hour, then straining off the liquor, and strewing the hot herbs from one end of the manger to the other, fastening the horse's head up with the rack rein, by which means he cannot evade the effluvia. In want of these, or where they are difficult to obtain, a mash made of ground malt, with boiling water, is a very substantial and proper substitute, into which stir two ounces of aniseed, and two ounces of caraway seeds, both fresh, and previously beaten to a powder in a mortar. This mash most horses will afterwards eat, when sufficiently cold for the purpose; which, with the effect of the fumes upon the throat, the nostrils, the glands, and the head, in general will promote a discharge, and relieve the subject.

FUNGUS is the too-fast shooting gra-

nulations of new flesh during the incarnation of wounds, particularly in horses, with whom it is invariably exuberant, and requires some degree of judgment in the suppression: it is too frequently attempted by Roman vitriol, corrosive sublimate, and other caustics; but they are only productive of disappointment, in constituting an eschar upon the surface, and leaving the cure at a more remote and uncertain distance, than before their application. Slight scarifications, both transverse and longitudinal, is a far preferable mode of treatment, and that followed by a dressing of lint covered with proper digestives.

FURNITURE, HORSE. In many parts of the United Kingdom, the saddle, bridle, cloths, and every other part appertaining to the body of the horse, pass under the denomination of horse furniture.

## G

GALLS OR GALLING. Good horses are often subject to gall upon their backs, and the utmost care ought to be taken to prevent or cure it. In long journeys, when horses are subject to gall, it is always proper to take off the saddle immediately, and examine whether the back be at all pressed, or pinched in any part. It will be well to examine it after an hour or two, to see what has happened; for often the part hurt will not shew at first, but will swell very violently afterwards. In this case, where the skin is not fretted, but a swelling comes on, a bag of coarse cloth should be filled with warm cowdung, and tied upon the swelling, which will not only prevent it from growing worse, but will take it often quite down; or the swelling may be well rubbed with brandy and vinegar, laying on some rags soaked in it. If the skin be broken, a plaster of any mild salve must be applied.

GALLOP. A well-known pace to which the horse is trained, and of which many kinds are enumerated, but two only worthy of regard, to wit, the *hand* gallop and the *full* gallop. Even these distinctions, however, are founded on the different degrees of velocity in which the animal is impelled, rather than on any peculiarity in the pace itself. In the gallop, the horse leads with one fore-leg somewhat advanced, but not so much beyond the other as happens in the canter; and, when he is urged to his utmost speed,

his legs are almost equally placed. The fleetest horses, when galloping, carry their bodies perfectly in a horizontal posture, and the fewer curves or successive arches are described, the more rapid of course is their progress.

Mr. Richard Lawrence justly observes, that, in every instance of progression, all bodies are retarded in proportion as they depart from a right line, whether this be horizontally or perpendicularly. "None but horses of great powers (says he) are able to gallop in this form: for, to supply the want of undulation in the body, they must bend their limbs in a greater degree; and hence the necessity of their standing perfectly on the centre of gravity. The action of the gallop being more extended than the canter, it is necessary that the horse should have his head more at liberty; for a horse cannot gallop out with his head reined up. Thus, in the swift gallop, he carries his head and neck nearly horizontal."

In galloping, the horse may lead with which fore-leg he pleases; the most usual way is with the right: but, whichever it be, the hind-leg of the same side must follow next; otherwise the legs are said to be disunited, and the gallop to be false. To remedy this disorder, the rider must stay the horse a little on the hand, and help him with the spur a little on the contrary side to that on which he is disunited. As for example, if he be dis-

united on the right side, he should help him with the left spur, by staying him as before on the hand a little, and also helping him at the same time with the calves of the legs.

Those who make a trial of the gallop should observe if the horse performs it equally, and should push him somewhat hard, that they may know by his step whether he has strength and vigour, and if he also be sensible of the spur.

In the manege many varieties of this pace were formerly enumerated, for instance, the following:—

**GALLOPADE.** In the manege, a hand-gallop, in which a horse galloping upon one or two treads is well united. The difference between working with one haunch in, galloping upon volts, and managing upon *terra a terra*, is, that, in the latter, the two haunches are kept subject, and also are within the volt; but, in galloping a haunch in, only one is kept subject.

*To gallop united*, upon the right foot, is, when a horse that gallops out, having led with either of his fore-legs, continues to lift that same leg always first; so that the hinder-leg on the side of the leading fore-leg must likewise be raised sooner than the other hind-leg. For instance, if the right fore-leg leads before the left, then the right hind-leg must likewise move sooner than the left hind-leg; and in this order must the horse continue to go on.

*To gallop false*, to disunite, to gallop on the false foot, is, when the horse, having led with one of the fore-legs, whether the right or left, does not continue to make that leg always set out first, nor to make the hind-leg of the same side with the leading leg to move before its opposite hind-leg; that is to say, the orderly going is interrupted.

A horse that gallops false—gallops with an unbecoming air, and incommodes the rider. If the horse gallops false, put him upon keeping the right foot and uniting, by bringing him to with the calves of your legs, and then with the spur that is opposite to the side on which he disunites. If he disunites to the right, prick him with the left heel.

**GALLOWAY** is the appellation given to that useful kind of small horse from thirteen to fourteen hands high; they are rarely to be seen of exact symmetry, uniform strength, and adequate action; but, if well-bred, their qualifications, and endurance of fatigue, exceed description.

**GAMBADOS**, OR **MUD BOOTS**, lately introduced for riding on horse-back:—they are suspended from the saddle, and prevent the horse splashing the legs; but they are *unsightly* and *cumbersome*; they cost 28s. create trouble in keeping clean; a pair of over-hauls or legings are to be had for eight or ten shillings, and are by far the more convenient.

**GAME**, are those animals for the preservation of which a multitude of statutes has been enacted, and consist of the following:—hare, pheasant, partridge, quail, heath fowl (black game), and moor game (red grouse). By some enactments which passed during the administration of the late Mr. Percival, snipes, wood-cocks, and rabbits, were added to the list of game, if they were killed by the gun or fowling-piece; but if taken in nets or springes, they were considered otherwise. Deer are also considered game; and by some antient statutes, the heron, mallard, duck, teal, &c. were included; but which do not appear to be considered so at present.

**GAME COCK.** See **COCKING**.

**GAMEKEEPERS** are a class of persons, delegated by legal prescription, to provide game for those by whom they are appointed; as well as to preserve and to protect it against a class of adventurers (poachers) by night, as also from an unfair and improper destruction of it by day.

At the moment of putting these pages together, we are aware that a great alteration is likely to take place in the game laws (in which the office of a gamekeeper is included) as the subject is under the consideration of the legislature. Nevertheless, in order to offer a thorough explanation of the subject, we deem it indispensable to give a consecutive view of the statutes upon the subject, as concisely, however, as is consistent with perspicuity.

By the 22nd and 23rd of Charles II. c. 25, s. 2, lords of manors and other royalties *not under the degree of an esquire*, (Willes, J. in the case of *Jones v. Smart*, said, that a lord of a manor is not an esquire by virtue of his manor or royalty; though in common acceptation he may be considered as such) may, by writing under their hands and seals, appoint gamekeepers within their manors and royalties, who then become authorised to seize all guns, greyhounds, setting dogs, or any other dogs for killing hares or rabbits; as well as snares, nets, &c. for the purpose of taking hares, partridges,

or other game, which may be found within their respective manors, used by unqualified persons. This act, however, does not authorise gamekeepers to kill game, but merely to preserve it.

The 5th of Anne, c. 14, s. 4, however, enables lords of manors to appoint gamekeepers to kill game. But, if he sell game, he is liable, on the oath of one witness, to be sent to the house of correction for three months, and kept to hard labour.

'Twenty-five, Geo. III. c. 5, s. 2, enacts, that every deputation of a gamekeeper granted to any person in England or Wales, shall be registered with the clerk of the peace for the county where the manor lies, for which such person is appointed. A neglect of this, as also of taking out a certificate of registry, incurs a penalty of twenty pounds. But gamekeepers to the royal family are exempt from the operations of this act.

If a gamekeeper be qualified in his own right, he has no occasion to enter his deputation. But a gamekeeper is not authorised by any statute to seize game which he may find in the possession of poachers, even on his manor, though it is lawful for him to take their dogs, nets, or other implements.

Also, gamekeepers, if found killing game off the manors for which they are appointed, are liable to the same penalties as unqualified persons. The only difference betwixt them in this case is, that a gamekeeper's gun and dogs are not seizable, while those of an unqualified person may be taken.

By 48, Geo. III. c. 93, s. 2, lords of manors are enabled to appoint and depute any person as gamekeeper whatever, whether acting in that capacity to any other person or not, or the servant of any other person qualified or unqualified, to kill game within a specified manor for the said lord's use, or for the use of any other person or persons to be specified in such appointment, or deputation; nor need such person be entered or paid for as the male servant of the lord or lady who gives the deputation.

Section 3 of this act gives the same authority as a regular gamekeeper.

The following cases are illustrative of the authority of a gamekeeper—*Vere v. Lord Cawdor and King*, M 50 G 3. In this, which was an action of trespass for shooting and killing a dog of the plaintiff's, there was a plea of not guilty, and special plea that Cawdor was the lord of the manor, and the defendant, gamekeeper;

that the dog was running after, chasing, and hunting divers hares, for the preservation of which the gamekeeper shot and killed the dog.

To this plea there was a demurrer; and after argument, Lord Ellenborough, J. C. said, the question is, whether the plaintiff's dog incurred the penalty of death for running after a hare in another's ground? And if there be any precedent of that sort, which outrages all reason and sense, it is of no authority to govern other cases. There is no question here as to the right of the game. But the gamekeeper had no right to kill the plaintiff's dog for following it. The plea does not even state that the hare was put in peril, so as to induce any necessity for killing the dog in order to preserve her. Judgment for the plaintiff. 11. E. R. 568.

*Thompson v. Christall*. The defendant, one of the Earl of Sefton's gamekeepers, who resides at Kirby, near Liverpool, having admitted to have had in his possession two game dogs belonging to the plaintiff, which he, the defendant, afterwards destroyed or otherwise disposed of, the plaintiff brought this action in the court of king's bench, and the defendant having suffered judgment to go against him by default, the case came before the sheriff at Preston upon a writ of inquiry, when the jury, after a full investigation of circumstances, gave the plaintiff twenty pounds damages, besides the costs.

If a gamekeeper shoot an unqualified person's dog, who thereupon shoots the gamekeeper's, and behaves insolently, the judge will direct very considerable damages. 2 Atkyn's Rep. 190.

Although by stat. 22 and 23 Charles II. c. 25, s. 2, a gamekeeper, so authorised, may search for dogs and engines, or seize the same for the use of the lord, or destroy them; yet it hath been adjudged that an authority from the lord of the manor is not of itself sufficient for the purpose, but that he ought to have a warrant from a justice of the peace: *Comberbach* 183, *Carpenter v. Adams*.

*Rogers v. Carter*. The plaintiff being gamekeeper within the manor of Ringwood, in beating for game within the said manor sprung a covey of partridges, which he shot at within the said manor. They took a second flight, and he pursued them out of the manor, but could not find them. As he was returning to the manor of Ringwood, he was met by the defendant, who asked if he had a

qualification? The plaintiff answered, I have a deputation from the lord of the manor of Ringwood. The defendant replied, you are now out of the manor, and demanded his gun, and took it from him. The plaintiff did not shoot out of the manor, but was three-quarters of a mile out of the manor with his dog and gun, with an intention to shoot at game.—By the Court. The question is, whether the defendant had a right to take the plaintiff's gun from him, while he was sporting for the purpose of killing game out of the manor of Ringwood?—And we are all of opinion he had no right. If he had killed game, where he was not a gamekeeper, he might have been convicted in the penalty of five pounds, but he was entitled to keep and have dogs, guns, and nets any where; and a gamekeeper's gun cannot be seized either in going to, or returning from, the manor, or in any other place. 2 Wils. 387.

**GAME LAWS.** The statutes which have been enacted for the preservation of game, and called Game Laws, by no means harmonize with the general spirit of British legislation; on the contrary, they are remarkable for the arbitrary spirit which pervades them, as well as for a sort of paradoxical complexity which renders some parts of them positively absurd and ridiculous. We are under the necessity, however, of giving a succinct view of them for reasons which we stated at the commencement of the last article.

*Trespass*, which is the entry by one person upon the ground of another, without the owner's consent, is, as far as relates to game, frequently converted into an engine of litigious oppression, and therefore merits consideration under the present head. To enter upon the ground of another, without his consent is a trespass, in the eye of the law, though no injury may have been sustained by the occupier of the land. It is a *wilful* trespass where the person has been warned not to come upon the ground; and *malicious*, where the intention to distress or injure the owner or occupier is evident.

In the sense we are here to consider it, *trespass* applies to qualified, as well as unqualified, persons, though not in an equal degree. The existing statutes upon this subject are fundamentally just and laudable; though it cannot be denied that they have been frequently resorted to (on account of game) merely as a colour to the most vindictive feelings.

An action of trespass may be supported for any unlawful entry on land, although no notice has been given; but, in that case, if the damages recovered be under forty shillings, and only the general issue has been pleaded, the plaintiff will in general recover no more costs than damages; whereas, when a trespass has been committed after notice, it is usual for the judge on the trial to certify that it is wilful, in which case the plaintiff will be entitled to full costs, however small the damages may be.

It is enacted by 42 Elizabeth, and 22 and 23 Charles II. c. 9, that where the jury who try an action for trespass, give less damages than forty shillings, the plaintiff shall be allowed forty shillings costs only; unless (8 and 9, William and Mary, c. 11) it shall appear that the trespass was wilful and malicious, and is so certified to be by the judge, in which the plaintiff shall recover full costs.

However, 4 and 5, William and Mary, c. 23, s. 10, enacts that every inferior tradesman, apprentice, or other dissolute person, may be sued for going upon another man's ground to hunt, &c. though he do no injury; and, if found guilty, shall pay full costs of suit. The reason for which is to discourage the temptation which might otherwise be afforded such persons of neglecting their proper business in pursuit of sport, to the injury of themselves and families.

Who are inferior tradesmen has not been legally defined. Upon the prosecution of a huntsman for being out with his master's hounds, it was decided that the huntsman did not come within the meaning of the act as an "inferior tradesman," or "dissolute person." In the case *Burton v. Mingay*, the question was, whether the defendant, a surgeon and apothecary, not qualified to kill game, came within the description of an inferior tradesman. For the plaintiff it was said, that amongst tradesmen no line can be drawn with respect to who are superior and who are inferior; but that the distinction which the legislature intended was between those who were qualified and those that were not; so that in this respect every tradesman is inferior who is not qualified. For the defendant it was urged, that every case of this kind ought to be determined on its own particular merits, and left to the jury. The court being equally divided, no rule was made.

A lord of a manor, unless he have a right of free warren (which is very seldom

the case) is as liable as any other man to the penalties just enumerated; or, in other words, he cannot sport upon the lands of another, even in his own manor, without permission of the owner or occupier of the land: a tenant can notice his landlord off the estate which he occupies, unless a clause in the lease (which is generally the case) gives the landlord privilege to sport. If a manor is to be strictly preserved, every occupier of land throughout such manor should sign a paper drawn up in the following manner:—

Sir,—I do hereby give you notice, and require you not to enter, or cause or procure to be entered, any of my closes, lands, or premises, situate and being in the manor of \_\_\_\_\_ or elsewhere, in the county of \_\_\_\_\_ with horses, dogs, or otherwise, in order to beat for, follow, or pursue any game, or for any other purpose whatsoever; and in case you do not as yet know the local situation of such, my said closes, lands and premises, I hereby give you notice that the same will be pointed out and shewn to you, upon reasonable application at my dwelling house, situate at \_\_\_\_\_. And I do hereby further give you notice, that in case, after you being served with this notice, you shall commit any trespass upon any part of my said closes, lands, or premises, you will not only be proceeded against as a wilful and malicious trespasser, pursuant to the statutes in that case made and provided, but will also be otherwise prosecuted for such offence according to law. Dated this \_\_\_\_\_ day of \_\_\_\_\_ in the year of our Lord \_\_\_\_\_

To Mr. \_\_\_\_\_

The notice may in general be in the above form, but where there will be no difficulty in so doing, it may be advisable either to point out the names or abutments of the closes in the notice, or to annex a sketch of them. It was held in the case of *Sellon v. the huntsman of the Berkely hunt*, sittings at Westminster K. B. after Trinity Term, 1816, that a general printed notice stuck up, purporting to be a notice that the "Stanmore Association" would prosecute all persons trespassing, but not signed by the plaintiff, nor addressed to the defendant, is not a legal notice not to trespass. In order to establish the notice in evidence, it is not necessary to give notice to produce the original notice, but it suffices to produce a duplicate made at the time; by Chambre, justice in the year 1802. 2 Bla. Com. Christian's edition,

147, with notes. 3 Bla. Com. 215, note b. 2 Campb. Rep. 110.

The oral notice of either gamekeeper, or lord of a manor is insufficient; but is deemed legal from the occupier of the land where the sportsman happens to be found. In all other cases, a written notice, similar to the sketch above given, and signed by all the occupiers of land in the manor, must be given to the trespasser. A gamekeeper cannot legally demand the name of a sportsman, or a sight of his certificate, without first producing his own deputation and certificate:—a gentleman must first produce his own certificate, before he is authorised to see the certificate of another person. In default of certificate, the name and address must be given; and any fictitious name adopted, or evasion resorted to, subjects the party to a penalty of £20.

It is supposed by some, that a person may continue to sport on the same manor all day, though he has been warned off in the morning. This cannot be the case—he may go through the manor to some road, but should he persevere in continuing his diversion for any unnecessary length of time, he becomes a *wilful* trespasser.

On the 12th of May, 1782, the following question of law was determined in the court of Common Pleas, viz. one gentleman brought an action against another, for trespassing upon the waste of his manor, by remaining there after notice to quit. Upon the trial, it was insisted that the waste was not that kind of property, as to be so strictly sacred from trespass as a manor; but it was over-ruled by the court.

At the summer assizes held at Bury, 1804, two cases were decided before Mr. Justice Heath and special justices, in which Lord Rous was plaintiff, and Sir Henry Smyth, Bart. and William Gill, Esq. two gentlemen of considerable property in Essex, were defendants, for a trespass upon the land of his Lordship, after the parties had received from him a written refusal to a note requesting permission to shoot, and after an oral notice had been given them by his Lordship's gamekeeper to leave the premises. The judge, after animadverting upon the improper conduct of these gentlemen, informed the jury, that he should certify upon the record that the trespasses were wilful and malicious, which would entitle the plaintiff to his costs, in consequence of which, the jury gave nominal damages only.

At the summer Hertford Assizes, 1809, the Earl of Essex *v.* the Hon. and Rev. Wm. Capel.—The plaintiff declared in trespass for breaking and entering certain closes of the plaintiff, and that with hounds, dogs, and horses, he hunted, sported, and went in, along, and over, the said closes, and trod down and destroyed the grass and herbage of the plaintiff. The defendant pleaded several pleas. First, the general issue, which he afterwards withdrew. Second, that as to breaking and entering the close, called Cashio-bury Park, the defendant, with divers other persons, who, as well as the defendant, were qualified to keep hounds, had found a fox in a certain place called Bricket Wood, not being the close of the plaintiff, and that a fox being a noxious animal, he hunted it with his dogs, hounds, and horses, and that the hunting the fox with dogs, hounds, and horses, was the only way of killing the fox. In the third plea it was stated, that such pursuit of the fox with dogs, hounds, and horses, was the most effectual and proper way of killing the fox. To these pleas the plaintiff replied, that, the hunting of the fox was not the only, or the most effectual, way of killing and destroying it; and further stated, that the trespasses were committed for the sport and diversion of the chase, and for the purpose of amusement and pleasure only. To these replications the defendant rejoined, that the trespasses were not committed for diversion and amusement, but as the only and most effectual and proper way of killing and destroying the fox.

Shepherd, Sergeant, for the plaintiff, contended, that the only question was, whether it was the defendant's object, to rid the country of noxious vermin, or whether he hunted for the sake of amusement?—If it was merely for amusement, the law does not sanction it. Even in the enjoyment of a man's own property, the maxim of the law is, that every man must so use his own, as not to injure his neighbours; if that is the law with respect to the enjoyment of property, then, unquestionably, as to the enjoyment of an amusement, the principle is doubly applicable; and no one can say, that under the pretence of destroying a noxious animal, it is lawful to trespass over every species of property a fox may go through. I should extremely doubt, whether, after starting a fox on one piece of land, persons have a right to follow it on the lands of another,

even if they do it for the destruction of the animal. In *Fentham v. Gundry*, the judgment of the court proceeded upon the plaintiff's admitting, that the way taken by the defendant was the only one to destroy the vermin, and therefore the action could not be supported.

Lord Ellenborough said, "the defendant states in his plea, that the trespass was not committed for the amusement and diversion of the chase merely, but as the only way and means of killing and destroying the fox. Now, if you were to put it on this question, which was the principal motive? Can any man of common sense hesitate in saying, that the principal motive and inducement, were not the killing of vermin, but the enjoyment of the sport and diversion of the chase? and we cannot make a new law, to suit the pleasures and amusements of those gentlemen who choose to hunt for their diversion. Their pleasures are only to be taken, when there is the consent of those who are likely to be injured by them; but they must be necessarily subservient to the consent of others. There may be such a public nuisance by a noxious animal, as may justify the running him to his earth; but then you cannot justify the digging for him afterwards—that has been ascertained and settled to be law; but even if an animal may be pursued with dogs, it does not follow that fifty or sixty people have, therefore, a right to follow the dogs and trespass upon other people's lands. I cannot see what it is that is contended for by the defendant. The only case which will at all bear him out is that of *Fentham v. Gundry*; if it be necessary, I should be glad that that case should be fully considered. I have looked into the case in the year book 12 Hen. VIII. pl. 9. That seems to be nothing more than the case of a person, who had chased a stag from the forest into his own land, where he killed it; and on an action of trespass being brought against the forester, who came and took the stag, he justified that he had made fresh suit after the stag, and it was held that he might state that he was justified, and the plaintiff took nothing by his writ. This is the case upon which that of *Fentham and Gundry* is built; but it is founded upon an *obiter dictum* of Justice Brooke, and it does not appear to me to be much relied on; but, even in that case, it is emphatically said by the judge, that a man may not hunt for his pleasure or his profit, but only for the good of the

common weal, and to destroy such noxious animals as are injurious to the common weal. Therefore, according to this case, the good of the public must be the governing motive." The jury, under his lordship's direction, found a verdict for the plaintiff.

A few words on the *legal property*, which qualified persons have in the game of which they are in pursuit, may not be altogether uninteresting. In general it continues so long *only* as the game remains within the limits of the manor or liberty of the owner; yet it is held, that if, after being started upon a person's own grounds, it be pursued on those of another, it will, nevertheless, be the property of him who started it, because the possession which he gained by finding it within his *own liberty* is *continued* by the *immediate* pursuit. 11 Mod. Rep. 75. But if it be started on *another man's ground* and killed there, it will belong to him on whose ground it was killed, this property arising *ratione soli*. Lord Raym. 251.

Moreover, if, having been started on another person's ground, it be killed on that of a *third person*, it will belong neither to him on whose ground it was started, nor to him on whose ground it was killed, but to the person who killed it, though he be guilty of a trespass on the grounds of both the other persons.

But if a stranger starts game in the *chase* or *free warren* of another man, and pursues it into the liberty of another, the property will continue in the owner of the chase or free warren, and the keeper may pursue and retake it, as it does not in law pass into a new liberty.

A qualified person cannot justify committing trespasses in the lands of any other person, whether such qualified person be, or be not, lord of the manor. If he commit a trespass upon land in the possession of any other person, he is liable to an action of trespass, let the damage be ever so small, which of course is the reason of giving notice, in order to entitle the plaintiff to full costs; but this notice will not entitle any person thereto but he who gives the notice, though plaintiff be tenant to the person who gives it; and no person but the occupier of the land can maintain action of trespass; and he may maintain trespass against any person entering thereon, and if notice hath been given to keep off, the person coming on afterwards will be a wilful trespasser; (if it appears on the trial that the trespass, however small, was committed after notice,

and the jury gives less than forty shillings damages, the judge is bound, under the stat. 8. and 9. Will. III. c. 11, s. 14, to certify that the trespass was wilful and malicious, in order to entitle the plaintiff to his full costs. 6 Term. Rep. 11.) and his looking for game will be no defence, though pursuing it (as hares by hounds after starting) would perhaps be defence; but even this is much doubted.

*Case.* The plaintiff in an action of trespass, was lord of the manor, defendant had freehold property in the same manor, and was entitled to common of pasture and turbary; he had received notice not to trespass on the moors belonging to the manor, for the purpose of hunting, shooting, &c. The question was, whether, after the above notice, defendant could lawfully enter and kill game upon the commons and waste lands within the manor.

*Opinion.* The circumstances of the defendant having a right of pasture and turbary, and a right of getting stones and slates on the moors, common, and wastes within Caton, in respect of his estates, will not justify his entrance upon those moors to hunt or kill game. If he has a right to enter to kill game there, it will be by virtue of a prescription for that purpose, or of a grant from the owner of the manor, or reputed manor, so to do; and such a prescription may be established by strong evidence of an uninterrupted course of usage, or of a usage in despite of prohibitions to the contrary, or exercised under circumstances shewing it to have been used as a claim of right, and not allowed or connived at as a courtesy or indulgence. The fact of the other freeholders of Caton (the manor) having been in the same habit of sporting within the manor, and of doing so not only on the commons, but on the inclosed lands also, is unfavourable, I think, to the defendant's establishing what he has done as a right in himself to sport upon the manor; and I think, in all probability the result of what has been done by the freeholders of Caton, and by the defendant among the rest, will, on investigation be deemed to have been founded on courtesy, and indulgence, and connivance, and not on right. If, however, the defendant can shew such a strong uninterrupted or adverse course of sporting on the waste lands of the manor, as will induce a jury to believe it founded on a privilege annexed to his estate in Caton, he cannot give that enjoyment in evidence in support of such a right under the general

issue, but must plead it specially, as a prescriptive right appurtenant to his estate, which is the only mode by which he can have an opportunity of trying that question.—G. S. H. Gray's Inn, 11th Feb. 1800.

Should the new game bill to be introduced pass into a law, it will very little affect the law of trespass.

*Qualification.* Of all the inconsistencies which ever marked the legislative regulations of any country, on the score of absurdity nothing can be found to equal what is called the Qualification for killing game in Great Britain; and why such a ridiculous and so outrageously unjust an enactment has been so long suffered to disgrace the statute book, why it has been suffered so long to stigmatize the good sense and wisdom of the British Parliament, is one of those anomalies which can be squared with no system of sound reasoning or well defined ideas.

The first time we meet with the subject, as laid down by legal enactments, is in the time of Richard II. when forty shillings per annum was deemed sufficient. Prior to the time of Richard II. it would seem that every man was entitled to kill game on his own land; and those who possessed the right of free warren could legally kill game upon any land within the franchise, though it might belong to another person. But by the 13th of Richard II. c. 13, no *layman*, who had not lands or tenements of forty shillings per annum; or *clergyman* not being advanced to ten pounds per year, shall keep any greyhound or hunting dog, nor use any instruments whatever for taking or destroying *gentlemen's* game, on pain of one year's imprisonment.

The 1st of James I. c. 27 rendered it indispensable for a person to possess an estate of ten pounds per annum, or goods to the value of £200, in order to qualification; unless he were the son of a lord or a knight, or the heir apparent of an esquire. In a few years afterwards the qualification sum was raised to £40 a year by the 7th of James I. c. 11.

The most important, however, of the statutes on this head, and that which alone in fact deserves the attention of the sportsman is the 22nd and 23rd of Charles II. c. 25. This is the most modern, and of late years has been uniformly acted upon whenever the subject was brought under legal investigation. By this, every person, not having lands or tenements of, or some other estate of, in-

heritance in his own or his wife's right (*a*) of the clear (*b*) yearly value of £100; or for a term of life, or having lease or leases of 99 years, or for any longer term of the clear yearly value of £150; other than the son or heir apparent of an esquire, or other persons of higher degree (*c*) and the owners and keepers of forests, parks, chases, or warrens, being stocked with deer or conies for their necessary use in regard to the said forests, parks, chases, or warrens, are declared to be persons by the law of this realm, not allowed to have or keep for themselves, or any other person (*d*) guns, bows, greyhounds, setting dogs, ferrets, coney dogs, lurchers, hays, nets, low bells, hare pipes, gins, snares, or other engines for the taking and killing of conies, hares, pheasants, partridges, or other game; but shall be prohibited to have, keep, or use the same.

The 5th of Anne, c. 14, s. 4, may be regarded as a prop or strengthener to the preceding; by this statute it is enacted, if any person not qualified as before stated, shall keep or use (*e*) any greyhounds,

---

(*a*) This is not to be understood of a tenant by courtesy, but of one whose wife is living—Co. Lit. 351.

(*b*) On this word, it has been held, that the estates must be clear of all mortgages or incumbrances created by the owner or by those under whom he claims—Caldecot's Cases 230. But an equitable estate of that value is sufficient.—Ibid.

(*c*) Esquires are—1. The younger sons of noblemen and their heirs male for ever. 2. The four esquires of the king's body. 3. The eldest sons of baronets or knights of the bath, and knights bachelors, and their heirs male in the right line. A justice of the peace is also an esquire for the time he holds his commission, but no longer—Blount. Persons of higher degree than esquires are colonels, sergeants at law, and doctors in the three learned professions; but neither esquires, nor any of these, are qualified, unless they have the requisite estate mentioned in the preceding part of the act; though their sons are qualified without any estate whatever. 1 Term Rep. 44.

(*d*) An unqualified person, therefore, cannot keep the dogs of a qualified person.

(*e*) These words being in the disjunctive, the bare keeping of one of these dogs is an offence, 1 Stra. 496. As to the using, it has been determined, that walking about with an intent to kill game, is a using within the statute.

setting dogs, hays, lurchers, tunnels, or any other engines, (*f*) to kill and destroy the game, and shall be thereof convicted upon the oath of one witness, by the justice of peace where such offence is committed, he shall forfeit five pounds—one half to go to the informer, and the other half to the poor of the parish; to be levied by distress (*g*) under the warrant of a justice, and for want of distress (*h*) the offender shall be sent to the house of correction for three months for the first offence; and for every after offence four months; and any justice of the peace or lord or lady of manors, are allowed to take away hares or other game, and likewise any dogs, nets, or other engines which shall be in the custody of any persons not qualified to keep the same, to their own use.

And by 22 and 23, Charles II. c. 25, s. 2, it is provided that gamekeepers or any other persons, by warrant of a justice of the peace, may, in the day time, search the houses or other places of any such persons prohibited by this act, to keep or use any dogs, nets, or other engines aforesaid, and the same seize and keep for the use of the lord of the manor; or otherwise cut in pieces and destroy the things so prohibited.

By 4 and 5, W. and M. c. 23. it is enacted, that if any inferior tradesman apprentice, or other dissolute person, shall hunt, hawk, fish, or fowl, (unless in company with the master of such apprentice, duly qualified) such persons may be sued for wilful trespass, on coming on any person's ground, and, if found guilty, shall pay full costs.

*Certificate.* The first act relative to game certificates was passed in the 25th Geo. III. This statute (c. 50, s. 8) levies a penalty of twenty pounds upon persons pursuing or taking game without a certifi-

(*f*) It has been held that a gun is not such an engine, the bare keeping of which is penal; it must moreover be shewn to be used for the destruction of game, 2 Stra. 1098. It is also observable, that though using a gun and a dog are both separately penal, yet, per Lord Kenyon, Chief Justice, if a person go out with a gun and a dog the same day, he is subject to but one penalty. 7 Term Rep. 152.

(*g*) Goods distrained for penalties under the game laws are not repleviable.

(*h*) The justice cannot commit, if the offender have effects sufficient to answer the penalty.

cate; and states further, that the certificate hereby directed to be taken out shall not authorise any person to pursue or take game, unless duly qualified by estate or otherwise. Also, the party thus offending to be liable to the same penalties as are inflicted by former acts now in force.

The list of game includes the following: heron, pheasant, partridge, heathcock, moor game, mallard, duck, wigeon, teal, woodcock, snipe, quail, and landrail; as also hares and rabbits. An act, passed in the 48th Geo. III. inflicts the before mentioned penalties for the pursuit or destruction of any of the animals just mentioned, by persons not duly authorised. See the article *GAME*.

There is an exception, however, in respect to woodcocks and snipes taken in nets or springes: as also in regard to conies taken in warrens or inclosed grounds by the proprietors of such places; or by any person in lands in his or her occupation, either by himself or herself, or by his or her direction or command.

By this act also, a different method of issuing certificates was ordered to be adopted. Instead of applying to the clerk of the county, the sportsman must pay three pounds fourteen shillings and sixpence into the hands of the collector of duties for the parish, ward, or place where he resides; the collector gives a receipt for the money, and on carrying this receipt to the clerk of the commissioner, acting for the district, a certificate will be given in exchange for the collector's receipt, without any further fee.

This act likewise (sect. 7) provides, that, should a gamekeeper quit his master or mistress before the expiration of the season for which his certificate has been obtained, the same certificate will be sufficient for the successor of such gamekeeper, provided the name of such newly appointed person is indorsed upon it, which the clerk to the commissioners is to do, upon application for that purpose, free of expence. Also, land-holders, legally authorised to appoint gamekeepers, may grant deputations to the servants of other persons for that purpose, whose certificate may be renewed in the same way.

Further, by this act, s. 10, the sportsman, when using dog, gun, &c. must produce his certificate, if demanded, to the assessor, collector, commissioner, or gamekeeper, inspector, or surveyor, or other person assessed as aforesaid; or the owner, landlord, lessee, or occupier of the land upon which he may be found sport-

ing; and must allow the persons, so demanding the same, not only to read, but to take a copy of his certificate, if they think proper. But in case the sportsman has not his certificate about him, he must declare to the person demanding, his christian and surname, and place of abode; as also the parish or place where the certificate has been issued. A refusal, or evasion, by fictitious name or otherwise, subjects the offending party to the penalty of twenty pounds.

By this act too (s. 12) a person sporting without a certificate, is liable to pay the duty for the year, and forfeit the sum of twenty pounds over and above, which is to be assessed by way of surcharge, in the district where the offence shall be committed. And finally (s. 11) the commissioners are to cause the names and residences of the persons taking out certificates to be published annually in the newspapers circulated in each county.

N.B. The royal family are exempt from the provisions of this act.

*Statutes to prevent the destruction of winged game, &c. at improper seasons of the year, Christmas Day, Sunday, &c.*—It is provided by 9 Anne, c. 25, s. 4, that if any person shall with hays, tunnels, or other nets, destroy in the *moulting season* (that is, between the first of June and the first of October) any wild duck, teal, widgeon, or other water fowl, such persons shall forfeit five shillings, and the nets, &c. used in taking such fowls to be destroyed.

The proper season for shooting grouse (called *red game*) is from the 12th of August to the 10th of December; that for heath fowls (commonly called *black game*) begins on the 20th of August and ends on the 10th of December; for bustards the season commences on the 1st of September and ends on the 1st of March. The penalty for destroying any of these

is (by the 13th of Geo. III. c. 55, s. 2) buying, or selling, or carrying, or even having in possession at any other season of the year, is any sum not exceeding twenty nor less than ten pounds, for the first offence; for every subsequent offence, a sum not exceeding thirty, nor less than twenty, pounds. One half of the penalty to be paid to the informer, and the other half to the poor of the parish; to be levied by distress, if not immediately paid: and in case no distress is to be had, the offender to be committed to the house of correction for any period not exceeding six months, nor less than three. However, by the 43 of Geo. III. c. 112, the season

for *black game* in the New Forest, Hampshire, does not begin till the first of September.

Also (by 4 and 5 W. and M. c. 22. s. 11) no person is allowed, between the 2nd of February and the 24th of June, to burn any gaig, ling, heath, furze, goss, or fern, on any mountains, heaths, or other places where moor game and heath fowls breed, upon pain of being committed to the house of correction for any time not exceeding one month, nor less than ten days.

The season for shooting *partridges* begins on the 1st of September and ends on the 1st of February; that for *pheasants* commences on the 1st of October, and closes at the same time as partridge shooting: the penalty attached to the taking, destroying, carrying, or having in possession, at any other period of the year, any of these birds, is five pounds for every pheasant or partridge; unless, however, such pheasant or partridge was taken at the proper season of the year, and kept in a mew or breeding place. The whole of this penalty to be paid to the informer, with full costs of suit.

As to woodcocks, snipes, quails, landrails, and rabbits, there is no specified time for their destruction, though snipes as well as quails, breed in this country. In fact, it does not appear that either woodcocks, snipes, or rabbits are that species of game the bare possession of which, in an unqualified person, is penal, unless it can be proved that the two first were *shot*, and the last caught in a place other than a warren, &c.

By the 35th, therefore, of Geo. III. c. 80, s. 1. it is provided, that if any person shall take or destroy any hare, pheasant, partridge, moor game, or heath game, between seven o'clock at night and six in the morning, from the 12th of October to the 12th of February; and between nine o'clock at night and four in the morning, from the 12th of February to the 12th of October; such person, upon conviction before a justice of the peace, upon the oath of one witness, shall forfeit a sum not exceeding twenty pounds, nor less than ten; for every subsequent offence, a sum not exceeding thirty pounds nor less than twenty—half to the informer, the other half to the poor.—Also, should a person be found *using* a dog, net, &c. with an *intent* to destroy the game above mentioned, at the specified prohibited times, he will be liable to the same penalties.

By s. 6, also of the same act, a person

who shall take or destroy any of the last mentioned animals on a Sunday or on a Christmas day (in the day time) or use dog, &c. for that purpose, will be liable to the same penalties as are inflicted for destroying game in the night, and to be convicted in the same manner.

Thirty-nine and 40 of Geo. III. c. 56, enacts, that if two or more persons be found in a forest, park, wood, plantation, field, meadow, or other open or inclosed ground, between the hours of eight o'clock at night and six in the morning, from the 1st of October to the 1st of February; or between the hours of ten at night and four in the morning, from the 1st day of February to the 1st of October; having any gun, &c. for the purpose and intent to take or destroy any hare, pheasant, partridge, moor or heath game; or if any person shall be found with fire arms, or other weapons aiding or assisting any such person as aforesaid, it shall be lawful for the owner of the place where any such person is found, or for his servants, or in fact, any person, to apprehend such offenders, and deliver them into the custody of a peace officer, by whom they are to be conveyed before a justice of the peace; who is authorized to commit such offenders to the house of correction, there to suffer such punishments as are directed to be inflicted on rogues and vagabonds. Or, in case such offenders make their escape, any justice, on the oath of one credible witness, may issue his warrant for their apprehension; and such persons, upon being apprehended, may be committed, upon the oath of one credible witness, the same as though he had been taken on the spot.

*Buying and Selling Game.* The 5th of Anne, c. 14, s. 2, enacts, that if any higler, chapman, carrier, innkeeper, victualler, or alehouse keeper, shall have in his possession any hare, pheasant, &c. (unless belonging to a qualified person) or shall buy, sell, or expose for sale, any such hare, &c. such offender shall forfeit the sum of five pounds; and the oath of one witness shall be a sufficient conviction—half the penalty to the informer, and the other half to the poor of the parish; to be distressed for if necessary; and in default thereof, the offender to be committed to the house of correction for three months; and for the second and every subsequent offence four months.

Also, s. 3 of the same act allows any person buying or selling game to inform against any other person so offending,

and to be allowed the same benefit as any other informer; and himself discharged from the above mentioned penalties.

By s. 4, the lord of the manor, or justice of the peace, may take to his own use any game which shall be found in the custody or possession of any unqualified person; unless protected by some qualified person.

If any person, whether qualified or unqualified, shall sell or expose for sale any hare, pheasant, &c. every such person shall be liable to a penalty of five pounds for every hare, &c.—on the oath of one witness—half to the informer, and half to the poor of the parish. Or, if any game be found in the house, shop, or possession of any poulterer, salesman, fishmonger, cook, or pastry cook, the same shall be deemed an exposing thereof to sale.

By 58 Geo. III. c. 75, the buyer (whether qualified or not) of any partridge, or any other game, is liable to a penalty of five pounds for every head of game he may purchase; and may be convicted on the oath of the very person who sold him the game; who, for his information, will not only be borne harmless, but entitled without further trouble to half the penalty; and is at liberty, if he think proper, to sue for and recover the whole.

*Tracing Hares in the Snow.* Fourteen and 15 Henry VIII. c. 10, inflicts a penalty of six shillings and eight pence for tracing and killing a hare in the snow. The 1st of James I. c. 27, inflicts three months' imprisonment on the offender for tracing or coursing a hare in the snow; unless the offending party pay to the churchwardens for the use of the poor, twenty shillings for every hare; or within one month after commitment, become bound, with two sureties, in twenty pounds each, not to offend again in like manner. Two witnesses are necessary in this case, as also two justices of the peace.

The same penalty, by the same act, is also inflicted for taking hares, with hare pipes, snares, or any other engines—two witnesses are necessary to convict the offender, before two justices.

Also by the 22nd and 23rd of Charles II. c. 25, if any person be found using or setting any snare or other engine, for the purpose of taking hares, he shall make the injured party such recompence as the justice shall appoint, and pay down immediately, for the use of the poor, a sum not exceeding ten shillings; otherwise to be committed to the house of correction for a time not exceeding one month. In

this case, the oath of one witness before one justice, is sufficient; but it must be done within one month after the offence is committed.

Hence the same penalty attaches for *shooting* a hare, even by a qualified person. Hares should be *coursed*, or killed by harriers.

*The Statutes relating to Rabbits.* By 3 James I. c. 13, s. 2, if any person shall, by night or by day, unlawfully enter into any park or grounds, inclosed with a wall, pale, or hedge, and used for the keeping of conies, and unlawfully hunt, take, chase, or slay, any conies, within such park or ground, against the will of the owner, and shall be thereof convicted, at the suit of the king or the party, at the assizes or sessions, he shall suffer three months' imprisonment, pay treble damages and costs to the party, to be assessed by the justices before whom he shall be convicted, and shall find sureties for his good behaviour for seven years, or remain in prison till he does.

And by 22 and 23 Charles II. c. 25, s. 4, if any person shall at any time wrongfully enter into any warren or ground lawfully used for keeping or breeding of conies, though the same may be not inclosed, and shall chase or kill any conies, against the will of the owner, or occupier, not having lawful title so to do, and shall be thereof convicted, within one month after such offence, by confession, or oath of one witness, before one justice, he shall yield to the party aggrieved treble damages and costs, and suffer three months' imprisonment, and so long after till he find sureties for his future good behaviour.

And by 5 Geo. III. c. 14, it is enacted, that if any person shall enter into such warrens or grounds in the night time, and take or kill any coney, against the will of the owner or occupier of the said ground, or shall be aiding or assisting therein, and be thereof convicted at the assizes, he shall be transported for seven years, or suffer such other punishment, by whipping, fine, or imprisonment, as the court shall award.

And by 9, Geo. I. c. 22, if any person, being armed and disguised, shall appear in any warren or place where hares or conies are usually kept, or unlawfully rob any such warren, or shall, though not armed and disguised, rescue any person in custody for such offence, or procure any person to join him therein, he shall be guilty of felony without benefit of clergy.

By 22 and 23 Charles II. it is provided, that no person shall kill or take, in the night, any conies upon the borders of a warren, or other grounds lawfully used for the breeding and keeping of conies, except such person be the owner of the soil, or the lawful possessor of the ground, whereupon such conies shall be killed, or be by him employed, upon pain of such satisfaction as the justices of the peace shall award; and also pay to the overseer for the poor, a sum not exceeding ten shillings; or, in default thereof, to be committed to the house of correction for a term not exceeding one month.

And by the same act, any person convicted of setting or using any snares, or other like engines for the taking of conies, shall be liable to the same penalties as in the last mentioned section.

A man cannot have an action on the case of another man's conies breaking into his ground; because they are in their natural liberty when they are out of the warren; but the owner of the soil may lawfully kill them while they are on his ground. Cro. Eliz. 547. 5 Co. 104.

The lord of the soil may make burrows in a common, and stock them with rabbits; and therefore a commoner cannot justify chasing them thence, *damage fasant*, for he ought to come there but to use his common; but if the lord surcharge the commoner, he is liable to an action for so doing. Cro. Jac. 195, 208, 229.

If the lord hath a right to put conies upon the common, and by an excess in number surcharges the common, and by the number of burrows made by the conies, prevents the commoner's cattle from depasturing the common, an action in such a case is the proper remedy, and the tenant may not of his own accord fill up the burrows and remove the nuisance. Cooper v. Marshall, 1 Burr. 259.

Conies in a warren shall go to the heir, and not to the executor. Co. Litt. 8.

*The law relating to pigeons.* Any person who shall shoot or destroy in any manner, any pigeon, shall, on conviction before two justices, on the oath of two witnesses, be committed to jail for three months; or pay for the use of the poor, twenty shillings for every pigeon; or, within one month after commitment, find sureties not to offend again.

However, by 2 Geo. II. c. 29, one witness and one justice are sufficient; to forfeit twenty shillings to the person who prosecutes, or be committed to the house

of correction and kept to hard labour for any term not exceeding three calendar months or less than one. Notwithstanding a man has a right to shoot any pigeons he may find destroying his corn.

A very severe statute was passed in 1816. It runs thus:—Whereas the laws now in force having been found insufficient to prevent idle and disorderly persons from going out armed in the night time, for the destruction of game: And whereas such practises are found, by experience, to lead to the commission of felonies and murders: For the more effectual suppression thereof, it is enacted, that if any person or persons shall unlawfully enter into, or be unlawfully found in, any forest, chase, park, wood, plantation, close, or other open or inclosed grounds, in the night time, that is to say, between the hours of eight of the clock at night and seven in the morning, from the first day of October to the first of March, or between the hours of ten at night and four in the morning, from the first day of March to the first day of October, in each and every year, having any gun, net, engine, or other instrument, for the purpose and with the intent to destroy, take, or kill, or shall wilfully destroy, take, or kill, any hare, rabbit, pheasant, partridge, heath fowl, commonly called black game, or grouse, commonly called red game, or any other game; or if any person or persons shall be found with any gun, firearms, bludgeon, or with any other offensive weapon, protecting, aiding, abetting, or assisting any such person or persons as aforesaid, every person so offending, being thereof lawfully convicted, shall be adjudged guilty of a misdemeanour, and shall be sentenced to transportation for seven years, or shall receive such other punishment as may by law be inflicted on persons guilty of misdemeanours, and as the court before which such offenders may be tried and convicted, shall adjudge; and if any such offender or offenders shall return into Great Britain before the expiration of the term for which he or they shall be so transported, contrary to the intent and meaning hereof, he or they, so returning, and being thereof duly convicted, shall be adjudged guilty of felony, and shall be sentenced to transportation for the term or terms of his or their natural life or lives.

A justice, on information before him, on the oath of any credible witness or witnesses, may issue his warrant for the apprehension of such offender or offend-

ers; and if, upon the apprehension of any such offender or offenders, it shall appear to such justice, on the oath of any credible witness or witnesses, that the person or persons so charged hath or have been guilty of any or either of the said offences, it shall and may be lawful for such justice to admit such person or persons so charged to bail, and, in default of bail, to commit such person or persons to the county gaol until the next general quarter sessions of the peace, or the next general commission of gaol delivery.

*Mutiny Act.* According to this, if any officer or soldier shall kill any kind of game, poultry, or fish, and be convicted, on the oath of one witness, before a justice, an officer so offending shall forfeit five pounds to the poor of the parish; but if a soldier be thus convicted, the commander-in-chief of the place shall pay twenty shillings for every such offence; and, if not paid within two days after demand by the constable or overseer of the poor, he shall forfeit his commission.

*The Statutes relating to Dogs.* It is a nuisance for any ferocious or mischievous dog to be at large and unmuzzled, and the owner may be indicted.

An action may be maintained against a man for keeping a dog *accustomed* to bite sheep: if it can be proved that the dog has ever bitten one before, it is deemed a sufficient proof of his being *accustomed* to do so.

Should the dog of one man fall upon that of another, he is justified in using violence even to the death of the offending dog, if it appear probable that he could not otherwise rescue his own dog.

If any person take up a lost dog, he must restore him on being demanded by the owner, or an action in trover may be maintained against him, in which he will be liable to damages and costs.

The 10th of Geo. III. c. 18, enacts, that if any person shall steal any dog or dogs, of any kind whatsoever, from the owner, or from any person entrusted by the owner with such dog or dogs, or shall sell, buy, receive, harbour, detain, or keep, any such dog or dogs, knowing the same to be stolen, every such offender, convicted on the oath of one witness, before two justices, shall, for the first offence, forfeit a sum not exceeding thirty, nor less than twenty, pounds, at the discretion of such two justices; together also with the charges previous to and attending such conviction, to be ascertained by such justices. In case such penalty be not im-

mediately paid, such justices may commit the offender to the house of correction, for a time not exceeding twelve, nor less than six, calendar months; or till the penalty be paid. For a second offence, the offender shall forfeit a sum not exceeding fifty, nor less than thirty, pounds; together also with the charges.

November, 1780, *Johnson v. Overall*. The declaration stated, that the defendant discharged a certain gun, loaded with gunpowder and bullets, and shot a certain dog of the plaintiff. The defence was, that only four sorts of dogs were in law of any value, and those specified. Dog in the declaration not specified, and therefore did not appear of any value.—Plaintiff nonsuited.

To an action of trespass for killing plaintiff's dog, the defendant may plead that the dog chased the rabbits in his warren, or the deer in his park; but not that he chased a hare into the defendant's land. 2 Morg. 265.

A dog is such a creature that a man may have a property in, and action has been brought for taking a hound, and the plaintiff recovered. The like of a bloodhound, greyhound, pointer, setter, spaniel, lurcher, and terrier.

If a person hunt upon the ground of another, such other person cannot justify killing of his dogs, as appears by 2 Roll. Abr. 567. But this has been overruled; and in the case of *Wadhurst v. Damme*, Cro. Jac. 44, it was held that a warrener may justify killing a mastiff dog in the warren pursuing the conies, to prevent his destroying them. So, if a dog run after deer in a park. 3 Lev. 28.

A man may justify an assault in defence of his dog. Cro. Eliz. 125.

It having been once known to the owner that his dog bit a person, he appears to be answerable for a subsequent mischief, although the person bitten had given some accidental occasion for it, as by treading on the dog's foot; for it was owing to his not hanging the dog on the first notice. And the safety of the king's subjects ought not to be endangered. 2 Stra. 1263.

*Of destroying the Eggs of Wild Fowl and Winged Game.* By 25 Hen. VIII. c. 11, it is enacted, that no person, from the first day of March to the 30th of June, shall destroy or convey away any eggs of wild fowl from any nest where they shall be laid, upon pain of imprisonment for one year; and of forfeiting for every egg of any crane or bustard, 20 pence; for

every egg of bittern, heron, or shoveld, 8 pence; for every egg of wild-duck, teal, or other wild-fowl, one penny.

And by James I. c. 27, s. 2, any person who shall take the eggs of any pheasant or partridge out of the nest, or wilfully break or destroy the same, shall, on conviction before two justices, by confession, or oath of two witnesses, be committed to gaol for three months, unless he pay to the churchwardens, for the use of the poor, 20 shillings for every egg; or within one month thereafter become bound, with two sureties in 20 pounds each, not to offend again.

GAMES OF ART are those in which the skill, judgment, and penetration of the player are immediately concerned, and upon which alone his success must entirely depend. In this class are included billiards, chess, draughts, cricket, fives, tennis, bowls, and some others, as well as a few upon the cards.

GAMES OF CHANCE. Those games are so called, which depend solely upon the turning up of a card, or the uncertain "hazard of the die."

GANGLION. A moveable tumour formed any where about the tendons of muscles and on the ligaments.

The cure is effected, in horses, by making an incision through its whole length, and afterwards dressing as in wounds in general; or they may be successfully extirpated, taking care not to wound the subjacent tendon or ligament, which can be generally avoided. Cutting away part of the cyst, and then digesting the rest away, by applying verdigrise or sublimate to it, will always succeed.

GANGRENE. A very great and dangerous degree of inflammation, wherein the parts affected begin to put on a state of putrefaction. Hence a gangrene appears to be a mortification in its beginning state, while yet the part retains some sense of pain, and some of the natural heat, by which last it is distinguished from a sphacelus, or thorough mortification, where there is no sense of warmth left.

The signs of a gangrene are when the symptoms of inflammation suddenly disappear, without taking away the cause; a dull sense in the part, softness, flaccidity, not rising again if depressed; pustules full of lymph, sometimes yellowish, at other times of a reddish colour, in and about the place inflamed. After this comes on a blackness of the flesh, &c. the signs of actual mortification.

## GANNET

**GANNET, THE, OR SOLAND GOOSE.** The Gannet is of the size of a tame goose, but its wings much longer, being six feet over. The bill is six inches long, straight almost to the point, where it inclines down, and the sides are irregularly jagged, that it may hold its prey with greater security. It differs from the cormorant in size, being larger; and its colour, which is chiefly white; and by its having no nostrils, but in their place a long furrow that reaches almost to the end of the bill. From the corner of the mouth is a narrow slip of black bare skin, that extends to the hind part of the head; beneath this skin is another that, like the pouch of the pelican, is dilatable, and of size sufficient to contain five or six entire herrings, which, in the breeding season, it carries at once to its mate or its young.

These birds, which subsist entirely upon fish, chiefly resort to those uninhabited islands where their food is found in plenty, and man seldom comes to disturb them. The islands to the north of Scotland, the Skelig islands off the coasts of Kerry in Ireland, and those that lie in the north sea off Norway, abound with them. But it is on the Bass island, in the Frith of Edinburgh, where they are seen in the greatest abundance. "There is a small island," says the celebrated Hervey, "called the Bass, not more than a mile in circumference. The surface is almost wholly covered, during the months of May and June, with their nests, their eggs, and young. It is scarcely possible to walk without treading on them: the flocks of birds upon the wing, are so numerous, as to darken the air like a cloud; and their noise is such that one cannot without difficulty be heard by the person next to him. When one looks down upon the sea from the precipice, its whole surface seems covered with infinite numbers of birds of different kinds, swimming and pursuing their prey. If, in sailing round the island, one surveys its hanging cliffs, in every crag, or fissure of the broken rocks, may be seen innumerable birds, of various sorts and sizes, more than the stars of heaven, when viewed in a serene night. If they are viewed at a distance, either receding, or in their approach to the island, they seem like one vast swarm of bees."

They are not less frequent upon the rocks of St. Kilda. Martin assures us, that the inhabitants of that small island consume annually near twenty-three thousand young birds of this species, besides an amazing quantity of their eggs. On these they principally subsist throughout the year; and from the number of these visitants, make an estimate of their plenty for the season. They preserve both the eggs and fowls in small pyramidical stone buildings, covering them with turf-ashes, to prevent the evaporation of their moisture.

The gannet is a bird of passage. In winter it seeks the more southern coasts of Cornwall, hovering over the shoals of herrings and pilchards that come down from the northern seas; its first appearance in the northern islands is in the beginning of spring, and it continues to breed till the end of summer. But, in general, its motions are determined by the migrations of the immense shoals of herrings that come pouring down at that season through the British channel, and supply all Europe, as well as this bird, with their spoil. The

gannet assiduously attends the shoals in their passage, keeps with them in their whole circuit round our island, and shares with our fishermen this exhaustless banquet. As it is strong on the wing, it never comes near the land; but is constant to its prey. Wherever the gannet is seen, it is sure to announce to the fishermen the arrival of the finny tribe: they then prepare their nets, and take the herrings by millions at a draught; while the gannet, who came to give the first information, comes, though an unbidden guest, and often snatches its prey from the fisherman, even in his boat. While the fishing season continues, the gannets are busily employed; but when the pilchards disappear from our coasts, the gannet takes its leave to keep them company.

The cormorant has been remarked for the quickness of his sight; yet in this the gannet seems to exceed him. It is possessed of a transparent membrane under the eye-lid, with which it covers the whole eye at pleasure, without obscuring the sight in the smallest degree. This seems a necessary provision for the security of the eyes of so weighty a creature, whose method of taking its prey, like that of the cormorant, is by darting headlong down from a height of a hundred feet and more into the water to seize it.—These birds are sometimes taken at sea, by fastening a pilchard to a board, which they leave floating. The gannet instantly pounces down from above upon the board, and is killed or maimed by the shock of a body where it expected no resistance.

These birds breed but once a year, and lay but one egg, which being taken away, they lay another; if that is also taken, then a third; but never more for that season. Their egg is white, and rather less than that of the common goose, and their nest large, composed of such substances as are found floating on the surface of the sea. The young birds, during the first year, differ greatly in colour from the old ones; being of a dusky hue, speckled with numerous triangular white spots; and at that time resembling the colours of the speckled diver.

The Bass island, where they chiefly breed, belongs to one proprietor; so that care is taken never to fright away the birds when laying, or to shoot them upon the wing. By that means they are so confident as to alight and feed their young ones close beside you. They feed only upon fish, as was observed: yet the young gannet is counted a great dainty by the Scots, and is sold very dear; so that the lord of the islet makes a considerable annual profit by the sale.

**GARGET.** A disease of the horse, is a swelling and inflammation of the head, affecting in particular the eyes and lips, and in the end inflaming also the gums and tongue. It is sometimes contagious. For the cure, the creature must be blooded every day till the inflammation subsides. Immediately after the first bleeding, give two ounces and a half of Epsom salts, dissolved in a pint of warm ale; after which, night and morning, the following drench

has been recommended:

Take of warm ale, half a pint;  
Salt prunella, or nitre in powder, half an ounce;  
Venice treacle, a quarter of an ounce.

Mix these together, and give it in one dose.

The animal must be kept clean, dry, and quiet. It may be necessary, however, to look into the mouth for blisters, which

generally appear upon the tongue; and, if there are any, break them, and dress them with ægyptiacum, or honey and vinegar. When the inflammation is likely to be considerable, local bleeding is very useful.

**GASKIN** or **GASCOIN** is that part of the hind quarter of a horse extending from the stifle (or inferior point of the thigh approaching the belly) to the bend of the hock behind; upon the shape, strength, and uniformity of which, the property, action, and excellence of the horse very much depends. If the gaskins are wide, and divide below the tail in a curvilinear arch on the inside, with a prominent swell of the muscle on the outside, it is not only indicative of great strength, but adds considerably to the symmetry and value of the horse when viewed behind. A horse well formed in the gaskins, is seldom badly shaped in the fore quarters; nor are they, in general, horses of inferior action; exclusive of which, they are insured from the very awkward defect of cutting.

**GATE NET.** A gate net is a principal part of the stock in trade of a professed poacher; and, in respect to hares, the most destructive nocturnal instrument that can be brought into use. In the first place, the poacher ascertains, in the course of the day, if possible, the field or fields where hares feed. The animals move from their seats or forms on the approach of dusk, and seem to spend some time in reconnoitring, as it were, the surrounding country, when they approach those places where they intend to feed. An hour after nightfall they will be feeding, and will continue in their feeding place for several hours; when they again scour the country, and return to their feeding ground several hours before day. The experienced poacher is well aware of this, and he acts accordingly. He repairs to the feeding ground, at the period when he knows the animals are supplying the cravings of their appetite, with his gate net, and attended by a dog. A lurcher, or an animal bred between the bull and terrier, is very well calculated for the purpose, as he will generally run mute; and, if not, the poacher is not very scrupulous as to the means he employs in rendering him silent, which he sometimes accomplishes by perforating his tongue by a red hot piece of iron. The net is made sufficiently wide so as to extend from one side of the gate place to the other, and about one yard in depth. The meshes are tolerably wide, even to admit

the head of a hare, by which means she is the more readily entangled. Two sticks, about half the thickness of a man's wrist, or perhaps scarcely so much, are stuck in the ground at such a distance from each other as to stretch out the net, or keep it extended, the top part of the net near to each end or extremity being stuck into notches, or rather clefts, sloping downwards, which have been already cut in the sticks; and thus, though the net is kept suspended, yet a slight pressure against it, pulls it out of the notches just mentioned. When prepared, the bottom of the net, for five or six inches or more, remains on the ground, the better to entangle the object. When all is ready, the dog is encouraged to scour the field, which he does with great alacrity. The hares of course immediately take the alarm, and making directly for the gate, run against the net, which is thus drawn out of the notched sticks, and they become entangled. The poacher or his accomplice has already stationed himself near the gate, and instantly puts a stop to the cry of poor pussy, and re-sets the net. If there is only one hare in the field, it is twenty to one but she is caught; if there are several, more than one might possibly run against the net at the same time; or, if the net is quickly re-set, a second may be caught, &c.—It might at first appear very strange, that, on occasions like these, hares should uniformly make for the gate, and to those who are unacquainted with the subject this will require a little explanation. It is very well known, even by those superficially acquainted with rural affairs, that the hare in general makes use of *meuses*, or small holes in the bottom of the hedge, in passing from one field to another, and hence it might appear that, in preference to making for the gate she would thread these holes or *meuses*; in the day time, in all probability, she would do so: but, strange as it may appear, she will avoid them, if possible, in the night, particularly if chased by a dog, or otherwise alarmed; and thus the poacher by merely placing his net at the gate is enabled to accomplish his object, without the trouble of setting wire snares or purse nets at the *meuses*. In fact, in order to be able to place a snare at the *meuses* or runs, he must have the benefit of daylight, whereas the gate net can be very well managed in the night; and where game is in tolerable plenty, vast numbers of hares may be caught with the gate net only. If there happen to be a

clear open gap in the hedge, it will be necessary to place a gate net there also, as the hare is just as likely to run through it, as to make her way out at the gate. When the hare is alarmed in the dark, she seems anxious to have as clear a course as possible; and cautiously avoids the meuses from fear perhaps of being caught by the briars.

It is said that the most effectual mode of counteracting the effects of the gate net is by painting the lower bar of the gate white: how far this might have the desired effect, the writer is not able to state from experience; but he is inclined to suppose that, though the hares at first might be somewhat alarmed at the white bar or bars, he supposes they would soon become familiar to the appearance, and conse-

quently act as if no appearance of that sort presented itself.—The gate net is placed by the poacher on the outside of the gate, and, as already observed, at about the distance of one yard.

GAZEHOUND. The name by which the species of dog we now term greyhound was formerly called. With what propriety an animal of almost every colour should be equally denominated *grey* does not appear; any more than at what particular period the change in appellation may have taken place. As the pursuit of the greyhound is entirely by *sight* and not by *scent*, it would appear that *gazehound* would be the more proper denomination of the two, and that the present is no more than a perversion of the original.

GAZELLE. An animal between a goat and a deer. The gazelles are, in general, inhabitants of the warmer climates; and contribute, among other embellishments, to add beauty to those forests that are for ever green. They are often seen feeding in herds, on the sides of the mountain, or in the shade of the woods; and fly altogether, upon the smallest approaches of danger. They bound with such swiftness, and are so very shy, that dogs or men vainly attempt to pursue them. They traverse those precipices with ease and safety, which to every quadruped else are quite impracticable; nor can any animals, but of the winged kind, overtake them. Accordingly, in all those countries where they are chiefly found, they are pursued by falcons; and this species of the chase formerly made one of the principal amusements of the upper ranks of people all over the East. The Arabians, Persians, and Turks, trained for this purpose, that kind of hawk called the *falcon gentle*, with which, when properly trained, they went forth on horseback among the forests and the mountains, the falcon perching upon the hand of the hunter. Their expedition was conducted with profound silence; their dogs were taught to hang behind; while the men, on the fleetest coursers, looked round for the game. Whenever they spied a gazelle at the proper distance, the falcon, with the swiftness of an arrow, flew to the animal; that, knowing its danger, endeavours, but in vain, to escape. The falcon soon coming up with its prey, fixes its talons, one into the animal's cheek, the other into its throat, and thus deeply wounds it. The falcon clings with the utmost perseverance, nor ever leaves its prey till it falls; upon which the hunters from behind approaching, take up both, and reward the falcon with the blood of the spoil. They also taught the young ones, by applying them to the dead animal's throat, and accustoming them betimes to fix upon that particular part; for if it should happen that the falcon fixed upon any other part of the gazelle, either its back or its haunches, the animal would easily escape among the mountains, and the hunter would also lose his falcon. They sometimes also hunt these animals with the ounce, called also the cheetah. This carni-

vorous and fierce creature being made tame and domestic, generally sits on horseback behind the hunter, and remains there with the utmost composure, until the gazelle is shewn; it is then that it exerts all its arts and fierceness; it does not at once fly at its prey, but approaches slyly, turning and winding about until it comes within the proper distance, when all at once it bounds upon the heedless animal, and instantly kills it, and sucks its blood. If, on the other hand, it misses its aim, it rests in its place, without attempting to pursue any farther, but seems ashamed of its own inability.

There is still another way of taking the gazelle, which seems not so certain, nor so amusing as either of the former. A tame gazelle is bred up for this purpose, which is taught to join those of its kind, wherever it perceives them. When the hunter, therefore, perceives a herd of these together, he fixes a noose round the horns of the tame gazelle, in such a manner, that if the rest but touch it, they are entangled; and thus prepared, he sends his gazelle among the rest. The tame animal no sooner approaches, but the males of the herd instantly sally forth to oppose him; and, in butting with their horns, are caught in the noose. In this way, both struggling for some time, they fall together to the ground; and, at last, the hunter coming up, disengages the one, and kills the other. Upon the whole, however, these animals, whatever be the arts used to pursue them, are very difficult to be taken. As they are continually subject to alarms from carnivorous beasts, or from man, they keep chiefly in the most solitary and inaccessible places, and find their only protection from situations of the greatest danger.

GENTLES. See BAITS.

GIFT OF GOING is a phrase which implies a horse's possessing a much greater portion of speed in action, particularly in trotting, than could well be expected from his shape and external appearance. When a horse is shewn for sale, having little to recommend him, rough in his coat, low in condition, awkward in shape, and without a single point of attraction, if he can scramble along at the rate of twelve or thirteen miles an hour, he is then said to possess the *gift of going*.

GIGS or FLAPS. Little swellings or bladders, with black heads, that grow in the mouth of a horse, on the inside of the lips and palate, which will sometimes appear as big as a walnut, and are so painful, that the horse will let his meat fall out of his mouth, or, at least, keep it

in his mouth unchewed. Gigs are cured by slitting them open with a lancet, and washing them afterwards with vinegar. But when they degenerate into what are called cankers, which are known by little white specks that spread into irregular ulcers, the best method then is to touch them with a small flat cautery, till the spreading is stopped, and to rub the sores three or four times a-day with ægyptiacum and tincture of myrrh. When, by this dressing, the sloughs are separated, they may be washed with a sponge dipped in alum, green vitriol, or sublimate water, if they continue to spread; or with a tincture made by dissolving half an ounce of alum, and two ounces of honey, in a pint of tincture of roses. Either of these will cure them, and are very useful in most disorders of the mouth.

GILLAROO TROUT, THE, is generally from twelve to eighteen, but increases so high as thirty pounds weight; these fish are esteemed for their fine flavour, which is supposed to exceed that of any other trout; their make is similar to the common, except being thicker in proportion to their length, and of a redder hue both before and after being dressed. The gillaroo is found in some of the

rivers in Ireland, is remarkable for having a gizzard resembling that of a large fowl or turkey; it is usual to dress the gizzards only, which are considered as very favourite morsels.

The celebrated John Hunter made this curious fish an object of his attention, and an extract from his observations upon it may not improperly here find a place: he states, that “one of the digestive organs of this trout being so very extraordinary as to have given name to it, is to be looked upon as its distinguishing characteristic: to throw some light upon the question, whether its resemblance to a gizzard be such as to render the appellation proper, it is expedient to state some general facts. Food of animals may be divided into two kinds; what does require mastication to facilitate digestion, and what does not: all animal food is of this latter kind; but grain, and many other substances which serve for aliment, require a previous grinding or trituration; and therefore animals which live on such food are provided with organs for that purpose. Such birds as live upon food, to digest which trituration is indispensable, have the power of masticating and digesting united in one part, the gizzard, which is for that end peculiarly constructed. In granivorous birds, therefore, a single organ answers both for the teeth and stomach of granivorous quadrupeds, (who have two powers distinct from each other, to masticate and digest their food; first being executed by teeth of a particular form, which serve as so many grindstones, for reducing their food to powder, before it is conveyed into the stomach for digestion) and consequently the gizzard alone of birds will point out the food of the species as clearly as the teeth and stomach together do in those animals in which the two offices of mastication and digestion are not joined together in the same part.

As it appears then to be the difference of the stomachs only that fits birds for their different kinds of food, it is evident that every gradation of stomach must be found among them, from the true gizzard, which is one extreme, to the mere membranous stomach, which is the other; since the food of the various species is from the hardest grain to the softest animal matter. The two extremes above-mentioned are easily defined, but they run so into each other, that the end of one and beginning of the other are quite imperceptible: similar gradations are observed in the food, the kinds suited to the two extremes, mixing together in different proportions, adapted to the intermediate states of the stomach.

A true gizzard is composed of two strong muscles placed opposite, and acting upon each other, as two broad grindstones. These muscles are united at their sides by a middle tendon, into which the muscular fibres are inserted, and which forms the narrow anterior and posterior sides of the flat quadrangular cavity, wherein the grinding is performed: the upper end of this cavity is filled up by the termination of the œsophagus, and the beginning of the intestine; the lower end consists of a thin muscular bag, connecting the edges of the two muscles together. The two flat lateral sides of the grinding cavity are lined with a bony substance, similar to a hard and thick cuticle.

## G I L L A R O O

The two large muscles may be considered as a pair of jaws, whose teeth are taken in occasionally, being small rough stones or pebbles which the animal swallows; and from the feeling on the tongue it can distinguish such of them as are proper from those that are smooth, or otherwise unfit for the purpose, which last it instantly drops out of its mouth. There are other animals which masticate their food in their stomach, but their teeth are by nature placed there: crabs and lobsters are thus formed. Some birds with gizzards have also a craw or crop, which serves as a reservoir and for softening the grain; but as all of them have not this organ it is foreign to our present purpose.

The gradation from gizzard to the stomach is made by the muscular sides becoming weaker and weaker, and the food keeps pace with this change, varying gradually from vegetable to animal; and we find that in granivorous animals of all sorts there is an apparatus for masticating their food, although of various kinds and differently placed." After describing the manner of carnivorous quadrupeds and birds taking and digesting their food, Mr. H. thus proceeds:—"Of all the fish I have seen, the mullet is the clearest instance of the structure of its stomach approaching to that of birds; its strong muscular stomach being evidently adapted, like the gizzard of birds, to the two offices of mastication and digestion. The stomach of the gillaroo trout holds the second place; but still neither of these stomachs can be justly ranked as gizzards, since they want some of the most essential characters; viz. a power and motion fitted for grinding, and the horny cuticle. The stomach of the gillaroo trout is, however, more circumscribed than that of most fish, and endued with sufficient strength to break the covering of small shell-fish, which will most probably be best done by having more than one in the stomach at a time, and also by taking large and smooth stones into it, which will answer the purpose of breaking, but not so well as that of grinding; nor can this fish's stomach possess scarcely any power of grinding, as the whole cavity is lined with a fine villous coat, and whose external surface every where appears to be digestive, and by no means fitted for mastication.

The stomach of the English is exactly of the same species with that of the gillaroo trout, but its coat is not so thick by two-thirds: (the English trout swallows shell-fish, and also pretty large smooth stones, which serve as shell breakers;) how far this difference in thickness of the stomach avails to make a distinct species, or barely a variety of the same, is only to be determined by experiment, which might be tried by putting some gillaroo trout, male and female, into water in which there are no trout, and observing if they continue unaltered.

The œsophagus in the trout is considerably longer and smaller than in any other classes of fish. The intestines are similar to those of the salmon, herring, sprat, &c. the pancreas is appendiculated (this name to the pancreas Mr. H. has adopted from its appearance). The teeth shew them to be a fish of prey. So far, therefore, (con-

cludes Mr. Hunter) as warranted by analogy, we must not consider the stomach of this fish as a gizzard, but as a true stomach."

Respecting the gillaroo trout, Mr. Pennant has the following remarks: "The stomachs of the common trouts are uncommonly thick and muscular; they feed on the shell-fish of lakes and rivers, as well as on small fish; they likewise take into their stomachs gravel or small stones, to assist in comminuting the testaceous parts of their food. The trouts of certain lakes in Ireland, as those of the county of Galway, and some others, are remarkable for the great thickness of their stomachs, which, from some resemblance to the organs of digestion in birds, have been called gizzards: the Irish name the species that has them, gillaroo trouts, and their stomachs are sometimes served up to table, under the former appellation. It does not appear to me (continues Mr. P.) that the extraordinary strength of stomach in the Irish fish should give any suspicion, that it is a distinct species: the nature of the waters might increase the thickness; or the superior quantity of shell-fish, which may more frequently call for the use of its comminuting powers than those of our trouts, might occasion this difference. I had an opportunity of comparing the stomach of a great gillaroo trout with a large one from the Uxbridge river; the last, if I recollect, was smaller, and out of season, and its stomach (notwithstanding it was very thick) was much inferior in strength to that of the former; but on the whole (says Mr. P.) there was not the least specific difference between the two subjects." From the foregoing investigations the gillaroo does not seem to constitute a new species of trout.

**GIMCRACK.** A grey horse, foaled in 1760, bred by G. Elliot, Esq. of Murrell-Green, Hampshire, sold to Mr. Green, and was afterwards the various property of Mr. Wildman, Lord Bolingbroke, Count Lauraguais, Sir C. Bunbury, and Lord Grosvenor.

Gimcrack was got by Cripple; his dam, Miss Elliot, by Mr. Grisewood's Partner; grandam (bred by Mr. Crofts) by Partner; great-grandam by the speedy stallion Bloody-Buttocks, a daughter of Old Greyhound, out of Brocklesby Betty.

At Epsom, May 31, 1764, Gimcrack won 50l. for four-year olds, 8st. 7lb. beating Mr. Everett's Antelope, Mr. Aldridge's Britannicus, and distanced three others:—at starting, Britannicus the favourite. At Guildford, June 15, he won 50l. weight for age, four-mile heats, beating Mr. Blake's Hazard, by Oronooko, 5 years old; Mr. Tate's Punch, by Snap, 6 years old; and Mr. Hawes's Lass of the Mill, 4 years old. At Winchester, July 12, he won 50l. for four-year olds, 8st. 7lb. beating Lord Castlehaven's Sappho, who was drawn after the first heat. At Bedford, August 7, he won 50l. give-and-take, beating Mr. Vernon's Rose, by

South, 4 years old:—Rose won the first heat, and Gimcrack the second, after which Rose was drawn. At Barnet, August 14, he won 50l. give-and-take, (carrying 7st. 7lb. 4oz.) beating Mr. Stoke's Lily, by Dormouse, 6 years old, 8st. 12lb. and Mr. Castle's Ladies' Pad, aged, 8st. 8lb. 4oz. Sir C. Eversfield's Matilda, 5 years old, 8st. 5lb. 14oz. and Mr. Carter's Young Driver, 6 years old, 9st. 4oz. At Reading, August 28, he won 50l. for four years old colts, 8st. 7lb. and fillies, 8st. 4lb. beating Mr. Hawes's Ladythigh, by Merlin; Lord Castlehaven's Sappho, and Lord Portmore's Brown Surrey. And at Burford, September 5, he won 50l. for four-year olds, 8st. 11lb. beating Sir J. Dashwood's Merlitta, by Merlin, &c. which was the seventh time of his winning, and only times of his starting that year. Gimcrack was sold to Mr. Wildman; and at Newmarket first Spring meeting, 1765, he won 50l. for horses rising five years old, 8st. 7lb. R. C. beating Mr. Vernon's Prophet, Sir J. Lowther's Treasurer, and Sir John Moor's South-West. Gimcrack was sold to Lord Bolingbroke; and in the same

meeting, at 8st. he received 250gs. forfeit from the Duke of Cumberland's Selim, 7st. 2lb. B. C. In the second Spring meeting, Gimcrack, 7st. 4lb. beat Mr. Panton's Rocket, aged, 8st. 7lb. B. C. 1000gs.—at starting, 6 to 4 on Rocket. At Newmarket in July, he beat Sir J. Lowther's Ascham, 6 years old, 7st. 10lb. each, B. C. 1000 gs.—at starting, 5 to 4 on Gimcrack. At Newmarket in October, he was beat (for the first time) by Bay Malton, allowing him 7lb. In the second October meeting, Gimcrack, 8st. beat the Duke of Cumberland's Drone, 4 years old, 6st. 7lb. B. C. 500gs.—at starting, 3 to one on Gimcrack. He was sold to Count Lauraguais; and in 1766, Gimcrack ran a match in France of 22 miles and a half within the hour, for a very considerable sum:—after which, he was brought into England, and at Newmarket in April, 1767, Gimcrack was second to the Duke of Kingston's Tyrant, 50l. beating Commodore, Beau, Virago, Flylax, Fop, South-East, Bounce, and Cripple. At Wisbech, June 5, he won 50l. give-and-take, (carrying 9st. 1lb. 12oz.) beating, at three heats, Mr. Wensley's Cub, 6 years old, 9st. 1lb. 12oz. and Mr. Blank's Trifle. At Ascot Heath, June 25, he won 50l. give-and-take, beating at three heats, Mr. Crosoer's Scrip, aged; Lord Orford's Mite, 5 years old, and two others. At Marlborough, July 1, he won 50l. for aged horses, 8st. 7lb. beating Mr. Bell's Selim, by Bajazet; and Mr. Quick's General:—6 to 4 on Gimcrack. At Wells, July 30, he won 50l. give-and-take, beating Mr. Beckford's Damon, and distanced two others. At Epsom, May 13, 1768, he won 50l. give-and-take, beating Mr. Merriot's Sloven, aged; Mr. Quick's Droll, 6 years old; and Mr. Strode's Ladythigh. At Ascot Heath, June 7, he won 50l. for six-year olds, beating Mr. Meadley's Nabob, 6 years old; and Mr. Larkin's Sloven, 6 years old:—at starting, 5 to 4 on Nabob. At Salisbury, June 30, he won the city silver bowl, with 30gs. added, 10st. beating Mr. Bevis's Selim, by Bajazet, aged; Mr. Strode's Leopardess, aged; and Mr. Adams's Gift, aged. Gimcrack was sold to Sir Charles Bunbury; and at Odsey, November 1, he won 50l. for five-year olds, 8st. six-year olds, 8st. 10lb. and aged, 9st. 4lb. beating, at three heats, Mr. Ellis's Spot, aged; Mr. Merriot's Juliet, 5 years old; Lord Farnham's Amazon, 5 years old; Mr. Strode's Ladythigh, 5 years old; Mr. M'Anella's Bar-

ley Corn, 5 years old, &c. At Newmarket, March 13, 1769, Gimcrack, 9st. won a Sweepstakes of 50gs. each, D. C. beating Mr. Vernon's Hermione, 5 years old, 7st. 9lb. and Lord Farnham's Amazon, 5 years old, 7st. 6lb. March 27, he won 50l. for six-year olds, 8st. 7lb. and aged, 9st. R. C. beating Lord Grosvenor's Cardinal Puff, aged; Lord Rockingham's Bay Malton, aged; Mr. Shafton's Hemp, 6 years old; Mr. Pratt's Phoenix, 6 years old; the Duke of Grafton's Bashful, 6 years old; Lord Farnham's Admiral, aged; Mr. Blake's Presto, 5 years old; Mr. Vernon's Chalfont, 5 years old; and Mr. Cross's Topper, aged: after which, Gimcrack was sold to Lord Grosvenor for 1200gs. and it was said, that a premium of 500gs. was immediately offered for him. March 29, Gimcrack, 9st. beat Mr. Vernon's Baber, 4 years old, 7st. 4lb. B. C. 300gs. April 17, Gimcrack, 9st. beat Lord Rockingham's Jack-O! 4 years old, 7st. B. C. 300gs.—7 to 4 on Gimcrack. At Newmarket, in April, 1770, he beat Lord Rockingham's Pilgrim, 10st. each, B. C. for 200gs. and the whip:—at starting, 5 to 2 on Gimcrack. At Newmarket, in April, 1771, he won 50l. for six-year olds, 8st. 7lb. and aged, 9st. R. C. beating Sir C. Bunbury's Bellario, aged; Lord March's Sportsman, 5 years old; Lord Bolingbroke's Chalfont, aged; Lord Orford's Hemp, aged; Mr. Wentworth's Myrmidon, 6 years old; Lord Farnham's Guardian, 6 years old; Mr. Cox's Tetotum, 6 years old; and Lord Rockingham's Tantrum, aged:—at starting, 2 to one on Bellario, and 6 and 7 to 1 against Gimcrack. This was the last time of his running.

Gimcrack was beaten ten times, viz.—at Newmarket in 1765, by Bay Malton; at Newmarket in 1767, by Tyrant; at Wantage, (same year) by Mr. Brereton's Otterley, &c. and at Odsey, by Tortoise, beating Favourite, Coriolanus, &c. at York in August, 1768, by Pilgrim, Chatsworth, Tortoise, and Beaufremont; and at Newmarket in October following, by Guardian and Icarius; at Newmarket in April, 1769, by Cosmo; at York in August following, by Chatsworth and Tortoise, beating Morwick-Ball, Bay Malton, and All-fours; at Newmarket in May, 1770, by Bellario, Nabob, Bashful, and Snipe; also, at Newmarket in October following, by Bellario and Petruchio, beating Chalfont, Fabius, and Pactolus.

Gimcrack measured about 14 hands one-fourth of an inch.

Gimcrack was a stallion at Oxcroft-Farm, near Newmarket, in 1772, at 25gs. and 5s.; in 1773, he was stinted to thirty mares, at 30gs. each, and 5s.; in 1774, 1775, and 1776, at 30gs. and 5s.; in 1777, at 25gs. and 5s.; in 1778, at 20gs. and 5s.; in 1779, at 10gs. and 10s. 6d.—He was sire of Lord Grosvenor's Little Gim, Grey Robin, Scramble and Jemima; of Sir C. Bunbury's Knick-Knack and Comedy; of Lord E. Bentinck's Vestris: of Mr. Peirse's Phaeton; Sir H. Harpur's Maiden; Sir J. Lade's Medley; Sir H. Featherstone's Surprise, &c. He served but few mares.

**GIRLE.** A roebuck of two years old.

**GIRTHS OF A SADDLE.** The strong web, or canvas straps, which being buckled under a horse's belly, serve to fix the saddle. It is a common error to girth a horse too strongly, not only when he is to be mounted, but even when standing clothed in the stable.

**GIVE-AND-TAKE PLATES** are those where the horses carry weight according to their height, by the regular standard of four inches to a hand. The fixed rules for a give-and-take are, that horses measuring fourteen hands, are each to carry nine stone; above or below which height, they are to carry seven pounds, more or less, for every inch they are higher or lower than the fourteen hands fixed as the criterion.—Example: a horse measuring fourteen hands, one inch and a half, will carry nine stone, ten pounds, eight ounces; a horse measuring thirteen hands, two inches and a half, will carry only eight stone, three pounds, eight ounces; the former being one inch and a half above fourteen hands, the other one inch and a half below it. The weight is, therefore, added or diminished, by the eighths of every inch, higher or lower weight in proportion; and these plates were so exceedingly popular some few years since, that very few country courses were without one of this description.

**GLANDERS.** We quote the following from the elegant and scientific Lectures of Mr. Percivall:—"Professor Coleman makes a division of glanders into two forms or species: *acute* and *chronic*. That species is *acute*, which, like other acute diseases, proceeds regularly through its course, and ends in death; that *chronic*, which, so long as it remains so, will not destroy the animal.

*Acute Glanders* may be defined to be, a specific inflammation and ulceration of the schneiderian membrane, more par-

ticularly of that part of it covering the septum: that appearing to possess a higher degree of susceptibility. It is generally attended with tumefaction of the submaxillary lymphatic glands: which tumour is simply the consequence of irritation.

The disease has been long known to be contagious—to be communicable through the medium of contaminated stables, and by inoculation; hence it has been concluded that it had no origin but contagion.

Those who are most conversant in the habits and diseases of horses, now know, that glanders, although demonstrably contagious, much more frequently arises from other causes: it is a disease that rarely or never spreads among horses at pasture, though a glandered subject may have been grazing among them; for, we learn from experiment, that although the disease is communicable by contact, the poisonous matter must be applied to a part bare of hair, and that, even then, the chances are in favour of the animal escaping infection unless the part has previously been, or happen to be in the act, abraded.

So far from contagion being the common cause of glanders, the Professor estimates that not one horse in a thousand, or even in ten thousand, so receives the disease. The poison of glanders is bred and diffused in an atmosphere rendered impure by repeated respiration, and by gaseous impregnations from the dung, urine, and perspiration, emitted in hot and foul stables. No vital being, neither animal nor vegetable, can maintain life in the total absence of pure air; and, according as an animal is from nature habituated to purity, so, generally speaking, it would seem that he suffers from atmospheric contamination.

The horse is an animal destined by nature to breathe an atmosphere of the purest kind; in proof of the salubrity of which to him, suffer him to remain in his native fields, and he will live long and ail nothing. But, bring him once into a state of domesticity, place him in a confined situation, in which he is compelled to breathe air that has been already respired, not only by himself but perhaps by other horses also, air impregnated with the exhalations from the urine, dung, and perspiration, and you sacrifice him a victim to malignant and fatal maladies. And none of our domestic animals, no more than horses, can tolerate this with impu-

nity. Therefore it is, that, in the degree in which a stable is foul and heated, from want of ventilation, we find its inhabitants the subjects of glanders, farcy, ophthalmia, &c. We seldom receive these cases from gentlemen's stables, because in general they are well-constructed, and kept clean, and do not contain many horses; but in collieries, breweries, post-houses, coach establishments, &c. where the stables are filthy from the dung and urine which stagnate in cavities in the pavement, for want of proper sewers to carry them off, and where the men are suffered to add to the mischief by plugging up every air-crevice they can find, we are continually witnessing the ravages of these very formidable diseases. The Professor was first led to adopt this notion of the spontaneous origin of glanders and farcy from an occurrence in our cavalry service which came to his knowledge. Many years ago (I believe about 1796) there was an extensive encampment upon Dover heights, from which the horses could not be removed until the autumnal season was far advanced, in consequence of the stables intended for their reception not being in a state of readiness: now, the stables were newly erected ones, notwithstanding which, great numbers of these horses, though previously in perfect health, soon after entering them became diseased; the greater proportion contracted grease, but several were attacked with glanders and farcy. He has since also received peculiarly satisfactory evidence of this in two memorable instances, in which stables which were hot and foul, and had from time to time turned out several glandered horses, were rendered equally salubrious with others adjoining them by proper ventilation and attention to cleanliness.

We now come to the relation of that celebrated experiment of the Professor's, by which, not only the contagious, but the constitutional, nature of glanders is proved beyond all doubt and idle speculation—that experiment which goes to disprove the assumption of Mr. Hunter, that the blood itself was never diseased. Of a horse afflicted with acute glanders, the Professor laid bare the carotid artery and jugular vein of the same side, and around each vessel placed a ligature. A pipe, furnished with a stop-cock, was then inserted and fastened into the artery; which was made to communicate, through the medium of a tube (a ureter, I believe) with another pipe introduced into the jugular vein of an ass: this animal hav-

ing been previously bled until he fell from exhaustion. In this manner, blood was conducted from the artery of the horse into the vein of the ass until the latter shewed every sign of perfect resuscitation. A circumstance occurred, however, in the revival of the ass, which, though it did not affect the issue of the experiment, may serve as a warning to future experimentalists; and that was, that, in consequence, it was thought, of transfusing more blood than was requisite, the ass appeared to be puffed out or swollen all over the body; this, however, was relieved in the course of four or five days, in which time the animal became glandered in a most violent degree; in confirmation of this, other asses were inoculated from this one, and they all unexceptionably shared the same fate. The loss of blood sustained by the horse was not sufficient to take away life.

Acute glanders, as was said before, consists in a specific inflammation and ulceration of the membrane lining the nose; by *specific* is meant, an inflammation not attended with the usual phenomena. If the inflammation could be as well recognised by any characteristic appearance as the ulceration is, then the horse ought to be pronounced glandered prior to the supervention of the ulcerative stage.

Glanders is not so prevalent in the summer as in the winter season; and it has, in several instances, been known to be epizootic, particularly when horses brought from camp or other external situations have been returned into warm and unventilated quarters. If precautions were taken to properly ventilate stables, the disease might be altogether eradicated. In further proof of the disease originating without contagion, we have instances of glanders breaking out among horses that have been embarked in a perfectly healthy condition on board of ships entirely new. In the expedition to Quiberon, the horses had not been long on board of the transports before it became necessary to shut down the hatchways: the consequences of this were, that the horses were almost suffocated with heat, and that almost all of them disembarked either glandered or farcied.

The acute glanders is the same disease, in regard to the nature of the poison, as farcy, and chronic glanders. Acute glanders hardly ever proves fatal without farcy making its appearance before death; on the other hand, farcy rarely or never of

itself puts an end to life, it being superseded commonly by acute, sometimes by chronic, glanders.

*Chronic Glanders* commonly affects but one side of the head; if, therefore, a discharge makes its appearance from one nostril alone, that of itself is strong presumptive evidence of the presence of this disease. This partial flux cannot come from the lungs, for, if it did, the other nostril would discharge too; it must have its issue from some part anterior to the larynx, consequently it can have no other source but the membrane of the nose or that portion of it lining the sinuses. Should it come from the nose, the membrane, most likely, will have a redder aspect upon that side of the septum than upon the opposite, or there may be a disposition to, or actual, ulceration. If the nasal discharge is considerable, and, at the same time, the animal to all appearances is in the enjoyment of good constitutional health, that is a circumstance which should serve to strengthen your suspicions: people cannot conceive how it is a horse can have glanders so long as he eats and drinks, and does his work like one in perfect health; this very fact, however, I repeat, is corroborative of an unfavourable prognosis. Another circumstance to be attended to, is, that the nasal flux has little or no fœtor: offensiveness of breath is pretty certain evidence that this disease is not present; not but what the two may exist in the same subject, but, fetid breath commonly proceeding from the lungs, and this chronic discharge coming from the sinuses of the head, the one is not in any way necessarily connected with the other. In glanders, the nostrils are contracted and gummed with inspissated discharge; but the flux is not offensive, or, at least, to the same degree as pulmonary fœtor is. Again, in glanders, generally speaking, there is on the same side from which the discharge comes, a defined swelling of the submaxillary lymphatic glands, which is attached closely and immovably to the side of the jaw: if it is a tumour of considerable size, one that is diffused and extends inwardly, or one that is very movable under the fingers, most likely it is not lymphatic, and therefore not connected with this disease. So far as the Professor's observation has gone, no such glandular swelling happens in common inflammation. In chronic glanders, then, the general health, appetite, spirits, &c. remain unimpaired; there is simply a discharge from one nostril,

which is unaccompanied by fœtor, and a circumscribed immovable tumor under the jaw on the same side. In some cases, however, the flux comes from both nostrils; here, commonly, both sets of glands are tumefied, the nature of which swellings will serve to direct the diagnosis; in addition to which, most probably, the animal's health continues good, and the discharge is not offensive. But, if cough is present with such a discharge, the submaxillary tumefaction uniformly diffused between the sides of the jaw, and there are feverish symptoms and evident impairment of the general health, the lungs are probably in this case the seat of disease. Still, in order that we may be certain about the existence of chronic glanders, we have no occasion to implicitly rely even upon these signs; for we may at once decide the point by the test of practical investigation. We have only to perforate (with a spill-gimblet) the frontal sinuses, and inject some clean tepid water into them: should the sinuses be healthy interiorly, the fluid will run from the nose either limpid as it is thrown in, or merely be tinged with blood; whereas, in a case of disease there, the water will carry down with it the matter lodged in the cavities. It is not uncommon, in this disease, to observe a horse discharging profusely for several days and then suddenly cease running altogether: this arises either from inspissation of the matter collected, or from the effusion of adhesive matter, within the sinus, which settles at the bottom of the cavity and plugs up the aperture by which it communicates with the chamber of the nose. During the interval of suspension no sign of disease remains but the submaxillary tumefaction; there is no discharge, and consequently there can be no source of contagion: but, the collection of matter continually augmenting, at length the plug is forced out, and the flux returns with more virulence than ever. In Smithfield, it used to be a common cheat to sell a horse having this disease, for a sound one, the trick consisting in stopping up the nostril of the affected side with a piece of sponge, which, of course, received and imbibed the discharge.

Though we have no specific remedy for chronic glanders, no more than we have for acute, the Professor has seen more cases of recovery from this than from the latter disease. When the discharge early in this affection becomes profuse, and continues long so, it will end, every now

and then, in a spontaneous cure ; at other times the flux will persist and run for years, and the horse, so long as the disease remains chronic, maintain his full health. Many horses of this description are to be found, in various parts of the country, working in road-waggon, brick-carts, agricultural machines, &c. &c. nevertheless, the disease is not only incurable by art, but is contagious ; the matter emitted from the nose has the property of propagating by contact either acute glanders or farcy, or even both.

With regard to remedies for glanders, either in its acute or chronic form, the Professor has nothing to offer. He has prescribed, by way of experiment, almost or quite all the mineral and known vegetable poisons : preparations of arsenic, antimony, copper, zinc, mercury, &c. hellebore, aconitum, digitalis, hyoscyamus, cicuta, belladonna, &c. &c. have

been, in various condemned subjects, internally administered ; but all without any specific or curative effect on this awful and obstinate malady."

GLEAD. A large kind of hawk, frequently seen on the moors or fens, where it breeds and forms its nest on the ground. It is very destructive to young grouse ; and will also seize goslings, young chickens, &c. They may be caught in traps baited with carrion, or part of a rabbit perhaps would be more tempting. They may be thus taken also with lime twigs.

GNAWPOST was a country plate horse of some celebrity, winning several for some years in succession. He was bred by Mr. Shafto ; was foaled in 1767 ; and got by Snap, out of Miss Cranbourne, who was got by the Godolphin Arabian, and bred by the then great Duke of Cumberland.

GODWIT, THE is taken at the same time, and in the same manner, with the ruffs and knots ; and when ready for market, each sells for five shillings and upwards. In the spring and summer it resides in the fens and marshes, where it rears its young, and lives upon small worms and insects. During these seasons it only removes from one marsh or fen to another ; but when the winter sets in with severity, (for the godwit continues with us the whole year) it seeks the salt-marshes, and the sandy shores by the sea-side, which for a great space are uncovered at the ebbing of the tide, where it walks like the curlew, and feeds upon the insects which there abound.

This bird is rather bigger than the woodcock, being in length from sixteen to eighteen inches, and between the tips of the extended wings twenty-eight inches broad. The weight twelve ounces. Bill four inches long, bending a little upwards, black at the point, gradually softening into a pale purple towards the base ; the under mandible the shortest ; the tongue sharp : the nostrils oblong ; and the ears large. A whitish streak passes from the bill to the eye ; the head, neck, and upper parts, of a dingy reddish brown, each feather marked down the middle with a dark spot. The fore part of the breast is streaked with black : in the female the throat and neck are grey or ash-coloured ; the belly, vent, and tail, are white, the latter regularly barred with black ; the six prime quill feathers are black, edged on the interior sides with reddish brown. In some birds the rump is white, and the chin nearly so ; the legs are not very long, naked to the middle of the second joint, and are generally dark coloured, inclining to a greenish blue.

The godwit is met with in various parts of the continent of Europe and Asia, as well as in America ; at Hudson's Bay, the red godwit, in particular, is so plentiful, that Mr. Atkinson, long resident at York Fort, killed seventy-two at one shot !

**GODOLPHIN ARABIAN.** A brown horse, foaled in 1724, and about 15 hands high, was first the property of Mr. Coke, who gave him to Mr. Roger Williams, keeper of St. James's Coffee-House, by whom he was presented to the Earl of Godolphin, in whose possession he continued, as a private stallion, till his death.—He was teaser to Hobgoblin in the years 1730 and 1731, and on the latter refusing to cover Roxana, she was put to the Arabian, and from that cover produced Lath; the first horse that the Godolphin Arabian got. To those who are thoroughly conversant with the Turf, it would be superfluous to remark, that he undoubtedly contributed more to the improvement of the breed of horses in this country, than any stallion before or since his time: It would be equally unnecessary to enumerate his get; but to those who are less acquainted with the annals of racing, suffice it to say, that he was sire of Cade, Regulus, Blank, Babram, Bajazet, and Old England; and may serve as a proof of the remark, that every superior horse of the present day partakes of his valuable blood.—He died at Hoggmagog, in 1753, in the 29th year of his age, and was buried in a covered passage, leading to the stable, with a flat stone over him, without any inscription.—In regard to his pedigree, from all that can be learned, none was brought into England with him, as it was said, and generally believed, that he was stolen.—It may appear trifling to notice the extraordinary affection shown by this Arabian to a cat, who lived in his stable; and which was more particularly manifested by his extreme inquietude on the death of that animal.

**GOLDFINDER.** A bay horse, foaled in 1764, bred by John St. Leger Douglas, Esq. of Spring Fields, Essex, and sold to Jenison Shafto, Esq.

Goldfinder was got by Snap; his dam by Blank; grandam (Lord Bolingbroke's Nettle's dam) by Regulus; great-grandam by Lord Lonsdale's bay Arabian, out of the Duke of Bolton's Bonnylass, the dam of Merry-Andrew, &c.

At Newmarket first spring meeting, April 5th, 1768, Goldfinder won a sweepstakes of 200gs. each, h. ft. (4 subscribers) 8st. 7lb. each, B. C. beating Mr. Vernon's Galba, by Sweepstakes, dam by Cade; and Mr. Fortescue's br. colt, by Old England, out of Bajazetta:—At starting, 5 to 4 on Galba. In the second spring meeting, April 29th, he won the Ascot stakes, of 25gs. each, 8st. 7lb. each, B. C. beating Sir John Moore's Baber, Lord Grosvenor's Bodfach, Mr. Vernon's Flush, the Duke of Ancaster's Jethro, Lord Rockingham's Monkey, the Duke of Bridgewater's Hercules, and Lord Gower's bay colt, by Tearing Robin. In the first October meeting, (Monday) he won a subscription of 200gs. each, h. ft. (8 subscribers) 8st. 10lb. each, B. C. beating

Lord Ossory's Fabius, Lord Grosvenor's Ancient Pistol, the Duke of Grafton's Baber, Lord Bolingbroke's Sejanus, and the Duke of Ancaster's Hostage:—At starting, 5 to 4 on Sejanus.—(Tuesday) Goldfinder, 8st. 7lb. received forfeit from Sir John Moore's bay filly, own sister to South-East, 8st. 2lb. B. C. 300gs. h. ft. In the second October meeting, (Thursday) he won the Contribution Stakes of 5gs. each, (20 subscribers, a non-subscriber paying 30gs. entrance); four-year olds, 7st. 7lb. five-year olds, 8st. 9lb. B. C. beating Lord Ossory's Metaphysician, 5 years old; Lord Bolingbroke's Tartuffe, 5 years old; Mr Strode's Ladythigh, 5 years old (30gs. entrance); and Lord Farnham's Cobbler, 4 years old. In the first Spring meeting, (March 31st) 1769, he won the 150gs. for horses, &c. rising 5 years old, 8st. 10lb. B. C. beating Lord Grosvenor's Ancient Pistol, Mr. Vernon's Flush, the Duke of Bridgewater's Darby, by Blank; and the Duke of Grafton's Charmer, by Blank. In the first October meeting, (Tuesday) he won a sweepstakes of 200gs. each, p. p. and the cup, (10 subscribers) for four-year olds, 7st. five-year olds, 8st. 5lb. six-year olds, 9st. 3lb.

and aged, 9st. 10lb. B. C. beating the Duke of Ancaster's Jethro, 5 years old; Sir C. Bunbury's Bellario, 6 years old; Mr. Vernon's Marquis, aged; Sir L. Dundas's A-la-greque, 6 years old; and Lord Rockingham's Cosmo, 5 years old:—[Lord Grosvenor's bay Halkin, 4 years old; Mr. P. Blake's Leader, 5 years old; Lord Bolingbroke's Sejanus, 5 years old; and Lord Barrymore's Thumper, aged, paid forfeit.]—At starting, 2 to 1 against Jethro, 5 to 2 against Goldfinder, 4 to 1 against Bellario, 5 and 6 to 1 against Marquis, 8 to 1 against A-la-greque, and the same against Cosmo.—On the Saturday, he won a subscription of 50gs. each, p. p. (6 subscribers) for five-year olds, 9st. each, B. C. beating the Duke of Ancaster's Jethro:—5 to 1 on Goldfinder. In the second October meeting, (Tuesday) he received 450gs. compromise from Mr. P. Blake's Leader, by Fearnought, 9st. each, B. C. 500gs. p. p.—On the Wednesday, he walked over for the 150gs. for five-year olds, 8st. 10lb. B. C.—And on the Friday, he walked over for the Contribution Stakes of 5gs. each, (20 subscribers) for all ages, B. C. In the second Spring meeting, 1770, Goldfinder walked over for a subscription of 25gs. each, (8 subscribers) for all ages, B. C.—On the Tuesday, in the first October meeting, he walked over for the cup, for all ages, B. C.—But on the day following, he broke down in his exercise, otherwise he was intended to have started for the King's plate against Eclipse.

Goldfinder was a horse of great speed and power; and was *never beat, or ever paid a forfeit*.—He was sold at Mr. Shaf-to's sale, at Newmarket, on Saturday, October 5th, 1771, to Sir Charles Sedley, for 1350gs.; and covered at Nuttal-Temple, near Nottingham, in 1772 and 1773, twenty mares, (besides those of the owner) at 20gs. and 5s.—In 1774 and 1775, thirty mares, (with the owner's) at 20gs. and 10s. 6d.—In 1776 and 1777, forty mares, &c. at 25gs. and 10s. 6d.—In 1778, fifty mares, (with those of the owner) at 20gs. and 10s. 6d.—After the death of Sir Charles Sedley, he was sold for 375gs; and in 1779, 1780, and 1781, at Coxe's Farm, near Micham, Surrey, at 10gs. and 5s.—In 1782, 1783, and 1784, at the same place, at 5gs. and 5s.

Goldfinder died in 1789, aged 25 years.

**GOLDFISH.** The goldfish are originally natives of China and Japan. About the year 1691 they were first introduced into England, but were not generally known until 1728, when a great number were brought over and presented to Sir Matthew Decker, who circulated them round the neighbourhood of London, from whence they have been distributed to most parts of the country; they have been known to attain the length of eight inches, and in their native place are said to equal the size of the largest herring.

**GOLDEN PLOVER.** See PLOVER.

**GONE AWAY!** is a halloo! in fox hunting, when the game breaks from cover, and goes away.

**GOOSE, THE BERNACLE.** The bill of this bird is very short and black, crossed with a flesh-coloured mark on each side. Part of the head, the chin, throat, under-parts, and upper tail-coverts, are white; and the rest of the head and neck, and the beginning of the back, are black. The thighs are mottled. Round the knee, the feathers are black; and the lower feathers of the back are the same, edged with white. The wing-coverts and scapulars are blue-grey; the ends black, fringed with white at the tip. The rump, tail, and legs, are black.

The Bernacle geese are not uncommon on many of the northern and western coasts of this kingdom, in winter; but they are scarce in the south, and only seen in inclement seasons. They leave our island in February, and retire northward to breed.

Of all the marvellous productions which ignorance, ever credulous, has so long substituted for the simple and truly wonderful operations of nature, the most absurd, and yet not the least celebrated, is the assertion of the growth of these birds, in a kind of shell, called *lepas anatifera* (goose-bearing shell), on certain trees on the coasts of Scot-

land and the Orkney Islands, or on the decayed and rotten timbers of old ships.

Numerous writers have mentioned and credited these circumstances; one of these, Maier, who has written a treatise expressly on this bird, says, that it certainly originates from shells: and what is, still more wonderful, that he himself opened a hundred of the goose-bearing shells in the Orkneys, and found in all of them the rudiments of the bird completely formed!

GOOSE, THE SOLAND.—See GANNET.

GOOSE, THE WILD. Wild geese inhabit the fens of England; and are supposed not to migrate, as they do in many countries on the continent. They breed in Lincolnshire and Cambridgeshire: they have seven or eight young; which are sometimes taken, and are easily rendered tame.

They are often seen in flocks of from fifty to a hundred, flying at very great heights and seldom resting by day. Their cry is frequently heard while they are quite imperceptible from their distance above. Whether this be their note of mutual encouragement, or only the necessary consequence of respiration, seems somewhat doubtful: but they seldom exert it when they alight in their journeys. On the ground they always arrange themselves in a line, and seem to descend rather for rest than refreshment; for, having continued in this manner for an hour or two, one of them with a long loud note sounds a kind of signal, to which the rest always punctually attend, and rising in a group they pursue their journey with alacrity. Their flight is conducted with vast regularity: they always proceed either in a line a-breast, or in two lines joining in an angle at the middle. In this order they generally take the lead by turns; the foremost falling back in the rear when tired, and the next in station succeeding to his duty.—Their track is generally so high, that it is almost impossible to reach them with a fowling-piece; and even when this can be done, they file so equally, that one discharge very seldom kills more than a single bird.

They breed in the plains and marshes about Hudson's Bay in North America: in some years the young ones are taken in considerable numbers; and at this age they are easily tamed. It is, however, extremely singular, that they will never learn to eat corn, unless some of the old ones are taken along with them; which may be done when these are in a moulting state.

Our common tame goose is nothing more than this species in a state of domestication.

GORGED. The common term for swelled legs, when their enlarged and distended state has been occasioned more by severe and hard work, than the effect of humours originating in a sily or morbid state of the blood. A horse having his back sinews flushed, and legs thickened, so as to go short and stiff in action, but not broken down, is said to be gorged. Having the same appearances from hu-

mours, or a viscidty of the blood, he is then said to be foul, and must be relieved by purgatives or diuretics, assisted by a great deal of hand-rubbing and regular friction. Gorged horses should be blistered, and turned out in time, by which they frequently get fresh again.

GOURDINESS, is another term for swelled legs, but of a different description, implying the kind of dropsical laxity of

of the solids, submitting to pressure, and recovering from its indentation when the pressure is removed. This kind of swelling is a gradual approach to the disorder called grease, at which it will soon arrive, if not counteracted speedily, by such evacuants and alteratives as may be thought most applicable to the case.

**GRAINING.** A fish about the size of a grayling; but found only in a few of the rivers in Great Britain.

**GRASS** is that well known produce of the earth, which is the proper food for horses in a state of nature and ease; but not of sufficient nutritive property for horses engaged either in severe or active exertions. Horses taken up from grass, and put suddenly to work, labour under an immediate and perceptible disquietude; the contents of the intestines are soon evacuated in a state of laxity, the frame displays a profusion of foul and foetid perspiration, the body bespeaks its own debility, and the perseverance of a few days demonstrates its emaciation. To horses having been whole months in constant use and work, alternately accustomed to diurnal drudgery, and the routine of the manger, grass, which is conjunctive liberty, must prove a sweet, a comfortable, a proper, and a healthy change: it not only, by its own attenuating property, proportionally alters the property of the blood, but affords, by the comforts of ease and expansion, a renovation of elasticity and vigour to the relaxed sinews, the exhausted spirits, and the battered frame.

Those who turn out horses to grass with a cough upon them, particularly if from a warm stable in a cold season, may expect to take them up with a short, husky, laboured asthmatic increase of the original complaint, or with tubercles formed upon the lungs; and those who turn out in the winter season, with a hope of obtaining the cure of cracked heels, or swelled legs, may probably take up with a confirmed grease.

**GRAVELLED.** A horse is said to be gravelled, when broken particles of stones, or small pebbles, are insinuated between the outer sole of the foot and the web of the shoe. The shoe should be tenderly taken off, by one nail at a time, in preference to tearing it off by main and sudden force, (according to custom,) the sole should be well fomented with good hot milk and water, then covered with an emollient poultice of linseed powder, milk, and two table spoonsful of olive oil, letting the same be repeated daily, till the

inflammation has subsided, and the tenderness gone off; when the bottom of the hoof may be hardened by two or three applications of a sponge dipt in vinegar boiling hot before the shoe is replaced.

**GRAVELING, THE,** *Last-Spring, Shedder, Gravel-Last-Spring, or Sampson*, known by these names in different countries, are found in all the rivers in which the salmon is met with; they are much like the salmon-fry. Various are the opinions respecting them; some contending they are the offspring of the sick salmon, which cannot leave the fresh water, and get to the sea; others, that they are absolutely the produce of the mixed spawn of different kinds of trouts. The baits, and method of angling for them, are the same as used for the salmon-fry.

**GRAY, or GREY.** See COLOUR.

**GRAYLING,** The, haunts rapid and clear streams, and particularly such as flow through mountainous countries; it is found in those of Derbyshire, Shropshire, Yorkshire, &c.; in Lapland, where it is very common, the inhabitants use its entrails, instead of rennet, to make the cheese which they get from the milk of the rein-deer. It is a fish of very elegant form; the body is less deep than that of the trout; the head small, with protuberant eyes, whose irides are silvery, speckled with yellow; the mouth is of a middle size, and the upper jaw the largest. The teeth are very minute, seated in the jaws and roof of the mouth, and feel like a fine file; the head is dusky, the covers of the gills are of a glossy green, yet, when in prime perfection, these parts are blackish, (differing in this respect from all other fish, being least beautiful when most in season;) the back is of a dusky green, inclining to blue; the sides of a fine silvery grey, (from which it derives the name;) yet when first taken, they seem to glitter with spangles of gold, and are marked with black spots irregularly placed. The side line is nearly straight; the scales are large, and the lower edges dusky; forming straight rows from the head to the tail, which is much forked; the large dorsal fin is spotted, the other fins are plain; it is rather hog-backed, and, from the nose and belly touching the ground together, it is conjectured that this fish feeds mostly at the bottom. In length, the grayling seldom exceeds sixteen inches. Mr. Pennant mentions one taken near Ludlow, above half a yard long, and weighing four pounds six ounces, as a

rare instance. One was caught near Shrewsbury that weighed full five pounds.

*Thymallus* is a name bestowed upon the grayling, on account of an imaginary scent proceeding from it similar to that of thyme; the name of *umbra*, which this fish also bears, has a far better derivation, for it is so swift a swimmer, as to disappear like the passing shadow.

Graylings are in great esteem, and their flesh is white and palatable all the year; they are in season from September to January, (some say are best in October, others in December,) and cannot be dressed too soon after they are caught. Graylings lurk close all the winter, and begin to be very active, and to spawn, in April, or early in May; at which time, and during the summer, near the sides, and at the tails, of sharp streams, they will take all the flies that trout are fond of: they rise bolder than the trout, and if missed several times, will still pursue; yet, notwithstanding they are so sportive after the fly, they are inanimate fish when hooked, and the sides of the mouth are so very tender, that unless nicely treated, when struck, the hold will frequently be broken. In September they retire in shoals to the lower end of still holes, just where the water becomes shallow, where they will take a fly at the top, which should be small; the camlet-fly is perhaps the best, and the hook No. 7 or 8.

When the water is not proper for flies, and they are angled for below the surface, use gentles (which they eagerly bite at,) wasp-grubs, or well scoured worms, as near the ground as possible. The cadbait, and other small insects which hide themselves in husks, they greedily feed upon, and have often been observed rooting up the gravel, and catching at every thing of this kind. Some, in fishing with gentles, have two or three hooks, and fish with them as with an artificial fly; others recommend the bait, or at least the lead above it, to drag on the ground, as they will rather take it there than ascend to do so, and use a running line; while others prefer a cork float, insisting that the grayling is more apt to rise than descend, and on that account keep the bait eight or ten inches from the bottom.

Walton has said the grayling will take a minnow, and his authority is not to be lightly questioned; but anglers of great experience have never found this bait successful. Graylings bite during the whole of cool, cloudy days; but the preferable

times, in spring and summer, are from eight in the morn until twelve, and from four in the afternoon until after sun-set; and from September to January, in the middle of the day.

**GREASE.** An inflammation and swelling in the heels of horses, sometimes confined to the neighbourhood of the fetlocks, at other times spreading considerably further up the legs, and secreting an oily matter, to which the disease is probably indebted for its name. The discharge has a particular odour, owing, we imagine, to the secretion of the heels being of a nature peculiar to them, as in the instance of the axilla of the human subject. Horses of the heavy class, with round fleshy legs, are the most liable to grease, and the white legs more than the rest. The disease is almost exclusively found in the posterior extremities.

Grease is brought on by sudden changes from a cold to a hot temperature: such as removing horses from grass into hot stables; from hastily substituting a generous after an impoverishing diet; from the negligence of grooms, in leaving the heels wet and full of sand; and from constitutional debility. The reason which has been assigned for the hind-leg of the horse being particularly the seat of this complaint is, the distance being greatest between that and the heart, in consequence of which the blood's circulation is weakest in these parts, and the pressure of its column overcome with the greatest difficulty by the vessels.

On the approach of this disease, and for several days previously to any striking appearances of swelling and inflammation, considerable pain seems to be experienced by the animal in the affected heel, as he is continually raising it from the ground, and cannot rest upon it without much uneasiness. At this early period the complaint may in general be carried off by a poultice of boiled bran and linseed powder constantly applied to the part, and kept moist with warm water; giving every night, or every second night, a mild diuretic, with plentiful exercise on dry and clean ground.

Where, however, there already exists considerable inflammation, the poultice, as before directed, may be used, and a diuretic of a rather strong quality, or else a purgative, may be administered as often as the state of the case shall seem to require. When the urgent symptoms have abated, and the inflammation has apparently ceased, the heel may be washed,

four times a-day, with the following solution :

Take of Rain or distilled water, one quart;

Alum, in powder, three ounces;

Vitriolated zinc, half an ounce.

Mix.

Should there exist any ulceration, it will generally be found to heal by the astringent power of this application ; but, if it prove tedious, look foul, and have an offensive smell, pledgets of tow or lint, spread with the following ointment, may be retained on the surface of the sores until they assume a healthy aspect, and may then be discontinued:

Take of Ointment of yellow resin, two ounces;

Verdigris, in fine powder, half an ounce. Mix.

In cases of grease, attended with debility and want of condition in the animal, medicines of a purgative or diuretic tendency may be thought improper, as contributing to the debility. Instead of these, something of an alterative quality should rather be preferred, as the following :

Take of Antimony, in fine powder;

Flowers of sulphur, of each, six ounces;

Linseed powder, two ounces;

Honey, sufficient to form a mass for twelve balls.

One of these should be given once or twice a-day. The diet should be generous, and the clothing and exercise plentiful.

Obstinate cases of grease may very frequently be cured by withholding the horse's allowance of water for two days, or even a longer period; let him then be ridden into the sea, and his extreme thirst will most probably induce him to drink pretty freely, notwithstanding the unpleasant flavour of that element. In this case, the salt-water will be found to act as an useful laxative and alterative. The process must be frequently repeated, wherever it may not appear injurious to the horse in any material respect.

We have introduced the latter simple method to the notice of the reader, having been assured of its efficacy from a respectable quarter, and that it afforded great benefit to a number of horses belonging to a regiment situated in a maritime quarter. Further trials certainly are required to establish it as a suitable remedy in these cases, and we have no doubt but many of our ingenious brethren will pay due attention to the hint. The greatest objection that can be entertained

against it seems to be the circumstance of depriving the horse of his usual supply of fresh water, which exclusion might, in some instances, be productive of injurious consequences. Would it not be a preferable plan to drench the horse very liberally with the sea-water, while fasting, in the morning? And, as some advantage is supposed to be also acquired by immersing the heels in it, he might afterwards be taken into the sea for that purpose only. Somewhat analogous to this means of curing the grease, in its earlier stages, is the practice of turning the horse into a salt-marsh. A run of a few months, indeed, on a salt-marsh, will frequently eradicate very tedious cases of grease, and where other and more active remedies have been tried in vain. Another method of cure we can strongly recommend, namely, turning the horse to grass, his heels being previously blistered.

There are but few cases of grease, in fact, that will not yield to one or other of the above methods of cure. The strength of all applications to the heels must bear a proper proportion to the irritation and inflammation apparently existing: and it is necessary to remark, that different medicines, though of a similar tendency, are often required; as any particular formula, when long made use of, is apt to lose its original power. We shall, of course, add a few other recipes, as substitutes, for each other, as their qualifications become diminished.

Take of Rain or distilled water, one quart;

Sugar of lead, six drachms;

Vitriolated zinc, half an ounce.

Mix.

Take of Rain or distilled water, one quart;

Vitriolated copper one ounce.

Mix.

Take of Rain or distilled water, one quart;

Vitriolated zinc, one ounce and a half. Mix.

Sometimes, indeed, applications in the form of lotions do not succeed so much to our wishes as the materials in a dry state; at such times powders may have a superior effect. We recommend the following:

Take of Alum, in fine powder, four ounces;

Vitriolated zinc, one ounce.

Mix.

Take of Alum, in fine powder, four ounces;

Vitriolated zinc,

Vitriolated copper, of each six drachms. Mix.

Take of Alum, three ounces;

Vitriolated zinc,

Acetated ceruse, of each six drachms. Rub them together into a fine powder.

After the heels have been well washed with soft soap and warm water, any of these powders may be slightly rubbed on the diseased parts; but it must be recollected, that they are seldom or never admissible where the inflammation is great, and they are only to be considered as the means of invigorating and of bracing the skin, with the vessels by which it is supplied.

Cases of grease have occurred in which the swelling was excessive, the discharge offensive beyond description, and the surface of the heels has been covered with numberless enlargements resembling grapes. When reduced to this miserable situation, it will, in general, be observed that the horse is accounted of little or no value; and indeed, as the disease has acquired an habitual influence, we may mitigate, but we can seldom quite exterminate it.

The horny substance which is frequently formed on heels of horses, in consequence of grease, should be removed either by the knife or by the actual cautery, as being offensive to the sight, and giving strangers a disposition to suspect that the animal is more liable to the disease than he really may be.

As preventives for the above disease, proper exercise, with attention to cleanliness, and rubbing the heels perfectly dry when coming into the stable, are principally to be depended upon. The legs of some horses are apt to swell at particular periods, but generally at the approach of winter; to such, a few diuretics will be serviceable, and will probably prevent the intrusion of grease. Where any debility exists, the habit must be strengthened

with nourishing diet, and plenty of gentle exercise.

**GREBE, THE.** The grebe is about the size of a duck, and its plumage white and black; it has short legs, made for swimming, and not walking; in fact, they are from the knee upward hid in the belly of the bird, and have consequently very little motion. By this mark, and by the scolloped fringe of the toes, may this bird be easily distinguished from all others.

As they are thus, from the shortness of their wings, ill formed for flying, and from the uncommon shortness of their legs utterly unfitted for walking, they seldom leave the water, and chiefly frequent those broad shallow pools where their faculty of swimming can be turned to the greatest advantage, in fishing and seeking their prey.

They are chiefly, in this country, seen to frequent the meres of Shropshire and Cheshire, where they breed among reeds and flags, in a floating nest, kept steady by the weeds of the margin. The female is said to be a careful nurse of her young, being observed to feed them most assiduously with small eels; and when the little brood is tired, the mother will carry them either on her back or under her wings. This bird preys upon fish, and is almost perpetually diving. It does not shew much more than the head above water, and is very difficult to be shot, as it darts down on the appearance of the least danger. It is never seen on land; and though disturbed ever so often, will not leave that lake, where alone, by diving and swimming, it can find food and security. It is chiefly sought for the skin of its breast, the plumage of which is of a most beautiful silvery white, and as glossy as satin. This part is made into tippets; but the skins are out of season about February, losing their bright colour; and in breeding time their breasts are entirely bare.

**GREEK FIRE.** See **GUNPOWDER.**

**GREYHOUND.** If we are to regard external appearances only, the greyhound may be placed at the head of the dog tribe, as there is an elegance in his form which will be vainly sought in any other variety of the canine race. At what precise period the greyhound first made his appearance in Great Britain is not known; but it must have been many centuries ago—all trace, in fact, of the origin of this animal is completely buried in the oblivion of antiquity.

In ancient times, the greyhound was considered as a valuable present, especially by the ladies, with whom it appears to have been a particular favourite; as, for instance, the wife of Robert Bruce,

## GREYHOUND

when a prisoner to Edward I. in the year 1301, had three men and three women servants, three *greyhounds*, plenty of game and fish, and the fairest house in the manor.

In a manuscript of Froissart, quoted by Montfaucon, there is an illuminated view of Isabella's splendid entrance into Paris in 1324; a *greyhound* attends her, with a flag powdered with *I'leur de lys* about his neck.

In a very old metrical Romance, called *Sir Eglamore*, a princess tells the knight, that if he was inclined to hunt, she would, as an especial mark of her favour, give him an excellent greyhound, so swift that no deer could escape from his pursuit—

Syr, if you be on huntynge founde,  
I shall you gyve a good greyhounde  
That is dunne as a doo:  
For as I am trewe gentylwoman,  
There was never deer that he at ran,  
That might escape him fro.

In the 10th and 11th centuries, the price of a greyhound and also of a hawk appears to have been the same as that of a man. During the reign of King John, greyhounds were frequently received by him as payment in lieu of money, for the renewal of grants, fines, and forfeitures belonging to the crown. The following extracts shew this monarch's attachment to greyhounds. A fine paid in the year 1203 mentions five hundred marks, ten horses, and ten leashes of *greyhounds*; another in 1210, enumerates, one swift running horse, and six *greyhounds*.

We make the following interesting extract from Carr's "Stranger in Ireland:"—"In the morning (says the author, who was then on his journey to Ireland) I wandered to a little church, which owed its elevation to this interesting circumstance: Llewelyn, the Great, who resided near the base of Snowden, had a beautiful *greyhound*, named *Gelert*, which had been presented to him by king John. One day, in consequence of the faithful animal, who at night always sentinelled his master's bed, not making his appearance in the chase, Llewelyn returned home very angry, and met the dog, covered with blood, at the door of the chamber of his child: upon entering it, he found the bed overturned, and the coverlit stained with gore: he called to his boy, but receiving no answer, he too rashly concluded that he had been killed by *Gelert*, and in his anguish, instantly thrust his sword through the poor animal's body. The honourable Mr. Spencer has beautifully commemorated the above event:—

His suppliant looks, as prone he fell,  
No pity could impart;  
But still his *Gelert's* dying yell  
Hung heavy at his heart.  
Aroused by *Gelert's* dying yell,  
Some slumberer waked nigh:  
What words the parent's joy could tell,  
To hear his infant cry.

## GREYHOUND

Nor scathe had he, nor harm, nor dread;  
 But the same couch beneath,  
 Lay a gaunt wolf, all torn and dead,  
 Tremendous still in death.

Ah! what was then Llewelyn's pain,  
 For now the truth was clear;  
 His gallant hound the wolf had slain,  
 To save Llewelyn's heir.

To mitigate his offence, Llewelyn built this chapel, and raised a tomb to poor Gelert; and the spot to this day is called *Beth Gelert*; or, the Grave of Gelert, “where never could the spearmen pass or forester unmoved.”

A further instance of the attachment of the greyhound is to be found among the specimens of early English Metrical Romance, by George Ellis, Esq. under the article *Sir Triamour*;

“The good greyhound, for weal ne wo.  
 Would not fro the knight go;  
 But lay and licked his wound:  
 He weened to have heald him again,  
 And thereto he did his pain;  
 Lo! such love is in a hound!

“He even scraped a pit for the dead body, covered it with moss and leaves, and guarded it with constant attention, except during the times when he was employed in securing his own subsistence.

“As his prey diminished, the length of his chase gradually increased; and at the close of the seventh year, at the festival of Christmas, he suddenly appeared, gaunt with hunger, an unexpected visitor in the hall of king Arragon. Such an apparition excited general surprise, and particularly attracted the attention of Aradas; but the animal, with a gentleness of demeanour, which belied his savage appearance, made the round of the tables and disappeared. He returned on the second day, again surveyed the company, received his pittance, and retreated. The king now recollected the dog, and gave orders to his attendants, that, if he should return, they should follow without loss of time, in the confidence that he would lead them to the place where Sir Roger and the Queen were secreted. On the third day of the festival, the hall was filled at an early hour, and Sir Marrack for the first time took his seat amongst the guests. The greyhound did not fail to repeat his visits, and with the rapidity of lightning, instantly sprung upon the murderer of his master:—

“He took the steward by the throat,  
 And asunder he it bote;  
 But then he would not 'bide:  
 For to his grave he ran.  
 Then followed him many a man,  
 Some on horse, and some beside,  
 And when he came where his master was,  
 He laid him down upon the grass,  
 And barked at the man again.

## GREYHOUND

“ The crowd who had followed him, being unable to drive him from the spot, returned with the tidings to the king, who instantly comprehended the whole mystery. He directed them to dig for the body, which they readily found, and which had been miraculously preserved in such a state of preservation as to be easily recognised. It was then buried in holy ground with all due solemnity, and the faithful dog shortly after expired on the tomb which was raised in memory of his master.”

The greyhounds, however, of these early days, were, in all probability, something similar to the Irish wolf dog, or large rough greyhound, from which the modern greyhound was bred no doubt, but, in the progress of what was considered improvement, very much altered in appearance, and became less powerful and less courageous. The modern greyhound exhibits a striking instance of what may be accomplished by attention in the way of speed and beauty ; but this has been obtained at the expense of strength, of courage, and of sagacity. We have many recorded instances of the striking sagacity of the greyhound of old ; but it is an incontrovertible fact, that the modern high-bred greyhound, on the score of sagacity, is inferior to every other variety of the dog tribe.—But to proceed—

In former days, such was the esteem in which greyhounds were held, that even their collars were composed of the most valuable materials. In Hawes's *Pastime of Pleasure*, written in the time of Henry VII. Fame is attended with two greyhounds ; in whose golden collars, *Grace* and *Governance* are inscribed in golden letters. These ornaments are often mentioned in the inventory of furniture, in the royal palaces of Henry VIII. In the Castle of Windsor, under the article *Collars*, may be found the following entries :—

“ Two *grayhounds'* collars of crimson velvet and cloth of gold, lacking *torretes*.”

“ Two other collars with the king's arms, and at the ende portculis and rose.”

“ Item.—A collar, embrowdered with pomegranates and roses, with torretes of silver and gilte.”—“ A collar garnished with stole work, with one shallop shelle of silver and gilte.”

In Henry the eighth's reign, the greyhound was distinguished as one of the king's beasts :—we read that at the siege of Tournay in the year of 1513, instead of a tent, Henry had a timber house with an iron chimney, and several pavilions, on the top of which stood “ the king's beastes, viz. the lion, the dragon, the antelope, the greyhound, and the dun cow.”

The old couplets that describe the greyhound are very exact in the points they recommend as necessary to form a complete greyhound.

“ Head like a snake,  
Neck'd like a drake,  
Back'd like a beam,  
Sided like a bream,  
Tailed like a rat,  
And footed like a cat.”

## GREYHOUND

In choosing a whelp, the choice was formerly governed by the weight, and that which was the lightest, it was supposed, would prove the nimblest and best. The raw-boned, lean, loose-made, and unseemly whelps, grew up well-shaped dogs; whereas, those that after three or four months appeared round, close trussed, and well built in every part, were not worth the rearing, seldom proving swift or comely. It was also an observation formerly, that *bitches* were commonly more *speedy* than the dogs.

The *time* to first try and train them to their game was at twelve months old, and there is little variation in this respect at the present day.

At two years old, the greyhound is full-grown, and the choice of one at that age was to be directed by his having a fine skin, with soft thin hair, a long lean head, with a nose sharp from the eye downwards; a full clear eye, with large eye-lids, little ears, a long neck bending like a drake, with a loose hanging weasand, broad breast, his body neither too long, nor too great, a back straight and square having a rising in the middle, a small belly, broad shoulders, round ribs, with a long space between his hips, a strong stern, a round foot with large clefts, and his fore-legs straighter than his hinder.

The breeding of the greyhound was recommended to be from the well-tried and best bitches, as an indifferent dog was supposed from such a cross to get better whelps than if the excellence was inverted, and the bitch but tolerable; the surest way to have the whelps excellent was to have both sire and dam good, and not to exceed four years old; if any inequality in their age, it was deemed better to be on the bitch's side, so that the dog was young.

The art of keeping a greyhound formerly, as well as entering him properly at his game, is thus described:—The keeping of a greyhound properly did not consist solely in the meat given him, but also in *kennelling*, *airing*, and *exercise*. When he was full in flesh, he was to have the chippings of bread in fresh broth. Milk and bread, butter-milk and soft bones, morning and evening, which was understood to keep him healthy. When he was low in condition or unwell, sheep's heads or feet with *the wool on*, chopped into small pieces and made into broth, with oatmeal and sweet herbs, was to be his daily food until he recovered his flesh and health.

The kennel was to be commodious, airy, the door towards the south, and the sleeping benches two feet and a half high, perforated with holes for the purpose of carrying off the urine: (A dog of any kind, will rarely eject either his urine or excrements on his bed; on the contrary, if closely confined, he will frequently howl for hours and even days, sooner than be guilty of what appears repugnant to his nature :) the straw on the benches was to be frequently changed, and the kennel kept extremely clean.

For greyhounds that were going to run, the following diet was recommended:—a peck of wheat, half a peck of oatmeal, ground and forced through a sieve; aniseeds bruised and liquorice were to be

## GREYHOUND

scattered amongst it; and it was then to be kneaded up with the whites of eggs and new ale, into small loaves, which were to be well baked. This was to be soaked in beef or other broth, and given to them immediately after their airings, morning and evening.

Previously to airing, the dog was to be brushed or rubbed with a hair cloth; he was then to be led out in a leash half an hour after sun-rising, to some plain where there were neither cattle nor sheep, there to be suffered to frisk about and empty himself, when he was to be led back. In the evening, all this was to be repeated; and in winter, he was allowed once a day the indulgence of the fire. It was recommended to keep him always in kennel, as it was thought his spirit and activity were thereby increased.

The exercise recommended for the greyhound was coursing: if the courses were long, twice a week was deemed sufficient; otherwise, every other day, and they were to be rewarded and encouraged with the *blood* of the hare. When they were first entered, it was allowable to give them every advantage—such as finding a young hare and giving her no law; but this was not allowable after he had once got blood.

A toast and butter, upon coursing days, was given early in the morning; if the dog killed the hare, he was not allowed to break her; the hare was taken from him, his mouth cleared of the fur; and he had afterwards the heart, liver, and lights given him.

After a very hard run, his feet were to be washed with salt and water; and after remaining in the kennel for half an hour, he was to be fed.

In regard to the modern feeding and training of the greyhound, opinions are by no means unanimous. Some insist that they should go through a regular course in these respects, something like the race horse. It is asserted, that a dog which has long courses to run should never be over-burthened with flesh, and that a greyhound too fat should have two doses of physic, allowing an interval of six days, and to be moderately blooded between the doses; his food afterwards to be dry boiled meat, occasionally changed to fine oatmeal, reduced to a proper consistency with boiled milk.—If with this preparative food, he be allowed to run two or three courses a week, and be regularly rubbed with a hair cloth all over until the flesh upon his loins becomes elastic and hard, so far as preparation goes, he is complete. Yet it is admitted that all this nicety, all this systematic training and preparation, have frequently been thrown away, and the same dog that has failed in running, when thus artificially prepared, has shewed itself far superior in its performances, when no course of training has been previously adopted.

One thing, however, the writer will venture to state, that the greyhound should, if possible, always be suffered to go at large. Nothing so much promotes health and activity as a state of perfect freedom.

As the greyhound has always been a great favourite amongst the sportsmen of these islands, all possible pains have been bestowed

## GREYHOUND

upon its improvement ; and its present superiority is to be principally attributed to the unwearied perseverance of the late Lord Orford. It was a predominant trait in the character of this eccentric nobleman never to do any thing by halves, and coursing (and consequently the greyhound) was his most prevalent passion. There were times when he was known to have fifty couple of greyhounds ; and he made it a fixed rule never to part with a single whelp till he had had a fair and satisfactory trial of his speed. In breeding, his Lordship introduced every possible experimental cross. He had strongly indulged an idea of a cross with the bull-dog, from which he could never be diverted ; and it is said that after patiently persevering for seven removes, he found himself in possession of the best greyhounds ever yet known ; giving the small ear, the rat tail, and the skin almost without hair, together with that innate courage which the high bred greyhound should possess, retaining which instinctively, he would rather die than give up the chase.

No man, it is said, ever devoted so much time, or sacrificed so much property, to practical and speculative sporting as Lord Orford. His invincible zeal for coursing, and his undiminished rage for its improvement, remained with him to the last. No day was too long, or any weather too severe, for him ; the singularity of his appearance was laughable. Mounted on a stump of a pie-bald pony, in a full suit of black, without either great-coat or gloves, his hands and face crimsoned with cold, and in a fierce cocked hat which faced every wind that blew ; and while his gamekeepers were shrinking from the sand-gathering blasts of Norfolk, on he rode, regardless of the elements.

At a particular period of life, “ when the springs of nature rose above their level,” there was a necessity for some degree of medical coercion to bring him again within the bounds of prudent regulation. During this period of unavoidable suspension from his favourite pursuits, the extreme attention shewn to him by a person who regulated his domestic concerns, so much influenced his nicer sensations, that he dedicated to her the most tender and grateful affection during her life. The circumstance of her death (though by no means young or handsome) so much affected his Lordship, that the nerves, unstrung, again gave way, and the former malady returned with increasing violence. He was at this time confined to his chamber, with an attendant necessary to the disordered state of his mind ; but, by some plausible pretext, he contrived to get his keeper out of the room, when he jumped out of the window, ran to the stables, and saddled his pie-bald pony, at the time the grooms and stable attendants were all engaged.

On that day, his favourite bitch, Old Czarina, was to run a match of some magnitude ; the gamekeeper had already taken her to the field, where a large party were assembled, equally lamenting the absence of his Lordship, and the cause by which his presence was prevented : when at the very moment of mutual regret, who should appear at full speed on the pie-bald pony but Lord Orford himself.

## GREYHOUND

All attempts and entreaties were in vain ; none had power to restrain him ; the match he was determined to see, and no persuasions could influence him to the contrary, The greyhounds were slipped, and Czarina won ; but, during the course, it was found impossible to prevent him riding after the dogs, more particularly as his favourite displayed her superiority in every stroke : when in the moment of his highest exultation and the eagerness of his triumph, he unfortunately fell from his pony ; and, pitching upon his head, he almost instantly expired.

Shortly after his Lordship's decease, his greyhounds were brought under the hammer of the auctioneer. The late Colonel Thornton was the purchaser of Jupiter, Czarina, and most of his best dogs, giving from thirty to fifty guineas each ;—for the purpose of improving the breed in Yorkshire ; and by the union of the Norfolk and Yorkshire blood, the best greyhounds in the world were produced.—Snowball and his brother Major were superior to all other greyhounds either before or since—they were the very perfection of the animal ; and perfection, at least in greyhounds, appears not to be stationary ; as, notwithstanding every possible exertion, the breed has deteriorated a few shades, though there are at present great numbers of very capital greyhounds.

There was something remarkable in Lord Orford's favourite bitch Czarina : she won forty-seven matches, without ever having been beat ; and shewed not the genial desire till she had completed her thirteenth year, when she brought forth eight whelps by Jupiter, all of which lived, and were excellent runners. She was the dam of Claret and Young Czarina, both of which challenged all Yorkshire and won their matches. Snowball and Major, the two celebrated dogs above-mentioned, who united the very best of the Norfolk and the Yorkshire blood, were got by Claret out of a favourite bitch belonging to Major Topham ; and a couple of the whelps, of which Major was one, were sent to Colonel Thornton ; as, in fact, a sportsman's privilege for the use of his dog. Major, from several private trials, was concluded to be a shade swifter than Snowball ; though the latter was considered as a more complete greyhound ; all countries were alike to him : and, taken “ for all in all,” he was regarded as the most perfect greyhound ever produced. He won four cups, couples, and upwards of thirty matches at Malton, and upon the Wolds in Yorkshire. Snowball ultimately challenged the world, and met with no competitor.

The following epitaph for the tomb of Snowball was written by his master, Major Topham :—

He who outbounded time and space,  
The fleetest of the greyhound race,  
Lies here !—At length, subdued by death,  
His speed now stopped, and out of breath.  
Ah ! gallant Snowball ! what remains  
Up Fordon's banks, o'er Flixton's plains,  
Of all thy strength—thy sinewy force,  
Which rather flew, than ran, the course ?

Ah! what remains? save that thy breed  
 May to their father's fame succeed;  
 And when the prize appears in view,  
 May prove that they are Snowballs too.

Snowball was a jet black; while his brother Major, who perhaps won as many matches as Snowball, was brindled. These two dogs won every match for which they contended; and the same remark will apply to their sister Sylvia. Sylvia in colour was similar to Major; and these were certainly the three best greyhounds ever produced at one litter.

In the year 1792, Schoolboy, the property of T. Clark, Esq. was a greyhound of much sporting celebrity at Newmarket and its vicinity. He ran a great number of matches over Newmarket, upon which very large sums were frequently depending, and never was beat.

Miller, the property of the Rev. H. B. Dudley, though he had little to boast on the score of pedigree, ran himself into much fame.

Mr. Mundy of Derbyshire possessed an excellent breed of greyhounds, and there are few coursers who have not heard of his celebrated *Wonder*. Excellent greyhounds are now to be found in all parts of the kingdom.

GREY PLOVER. See PLOVER.

GRICE. A small wild boar.

GRIPES. See COLIC.

GROGGY implies a tenderness and defect in action, either from a chest, or foot, founder, or an injury sustained in the back sinews. Horses of this description, although they come crippled out of the stable, yet when the circulation is increased by action, and the stiffness gone off, their exertion is incredible, and their endurance of fatigue beyond conception.

GROOM. A man who looks after horses. The duties of a groom consist in dressing, dieting, exercising, and administering physic to them. He should demean himself after so gentle and so kind a manner towards his horses as to cause them to love him; for a horse is much attached to man. Hence, if dealt with mildly and gently, kindness will be reciprocal; but, if the groom or keeper be harsh and choleric, he will put the horse out of patience, make him rebellious, and occasion his biting and striking. So attentive should a person who has the care of horses be to this circumstance, that he should frequently talk to them, giving them good words, &c.

The qualifications necessary in a groom are obedience, fidelity, cleanliness, patience, diligence, and good temper. He ought to love his horse in the next degree to his master; and endeavour to obtain,

by fair usage alone, his implicit obedience. If he knows, indeed, how to act in this manner towards his master, he will the better be able to teach it his horse; and both the one and the other are to be obtained by fair means, rather than by passion and outrage. For those who are so irrational themselves as not to be able to command their own passions, are not fit to undertake the reclaiming of a horse, which is by nature an irrational creature. He must, then, put in practice the patience which he ought at all times to be master of; and by that, and fair means, he may attain his ends.

The next thing requisite to a groom is neatness, as to keeping his stable clean swept and in order. The saddles, housing-cloths, stirrups, leathers, and girths, should be kept perfectly clean. Great diligence is requisite in the daily discharge of this and the foregoing duties. But, above all, his vigilance is required to make the earliest discovery of any the smallest change, whether casual or accidental, either in his countenance, as symptoms of sickness; or in his limbs and gait, as lameness; or in his appetite, as forsaking his meat; and immediately upon any such discovery in the horse, to seek out a suitable remedy.

GROVELLING. A deer is said to *feed grovelling*, when he eats as he lies on his belly.

BIRDS, ETC. *Plate IV.*

GROUSE, or BLACK COCK, *p.* 393.

HARE, *p.* 415.

HERON, *p.* 444.

## G R O U S E

**GROUSE.** The red grouse, or moor game, is the most common of the grouse tribe in England ; but the cock of the wood, the heath cock, or black game, and the ptarmigan, or white grouse ; are all birds of a somewhat similar nature ; and are found in heathy mountains and piny forests, at a distance from mankind. They might once indeed have been common enough all over England, when a great part of the country was covered with heath ; but at present their numbers are thinned.

The cock of the wood, or wood grouse, will sometimes weigh fourteen or fifteen pounds ; the black cock, of which the male is nearly all black, though the female is of the colour of the partridge, generally weighs three or four pounds, the female is one third less ; the red or common grouse is about half as large again as the partridge, and its colour much like that of a woodcock, but redder ; the ptarmigan is somewhat less, is of a grey-ash colour, except in winter, when it assumes the colour of the snow amongst which it resides.

The cock of the wood is chiefly fond of a mountainous and woody situation. In winter he resides in the darkest and inmost parts of the woods ; in summer he ventures down from his retreats to commit depredations on the farmer's corn.

This bird, when in the forest, we are told, attaches himself principally to the oak and pine tree ; the cones of the latter serving for food, and the thick boughs for a habitation. He even makes a choice of what cones he shall feed upon ; for he sometimes will strip one tree bare before he will deign to touch the cones of another. He feeds also upon ants' eggs, which seem a high delicacy to all birds of the poultry kind, as well as upon insects in general ; cranberries are likewise often found in his crop ; and his gizzard, like that of domestic fowls, contains a quantity of gravel, for the purpose of assisting his powers of digestion.

At the earliest return of spring, the cock of the wood begins to feel the influence of the season. During the month of March, courtship is continued, and is not relinquished till the trees have all their leaves, and the forest is in full bloom. During this season, the cock of the wood, we are told, is seen at sun-rise and sun-setting extremely active, upon one of the largest branches of the pine tree. With his tail raised and expanded, like a fan, and his wings drooping, he is seen walking backward and forward, his neck stretched out, his head swollen and red, and exhibiting a thousand ridiculous postures : his cry, on these occasions, is a kind of loud explosion, which is instantly followed by a noise like the whetting of a scythe, which ceases and commences alternately for about an hour, and is then terminated by the same explosion.

During the time this singular cry continues, the bird seems entirely deaf, and insensible to every danger ; whatever noise may be made near him, or even though fired at, he still continues his call. Upon all other occasions, he is one of the most watchful birds in nature ; but now he appears entirely absorbed in his instincts ; and seldom leaves the place where he first begins to feel the accesses of desire.

## G R O U S E

This extraordinary cry, which is accompanied by a clapping of the wings, is no sooner finished, than the female hearing it, replies, approaches, and places herself under the tree, whence the cock descends to impregnate her.

The female is much less than the male, and entirely unlike him in plumage, so that she might be mistaken for a bird of another species: she seldom lays more than six or seven eggs, which are white and marked with yellow, of the size of a hen's egg: she generally lays them in a dry place and a mossy ground, and hatches them without the company of the cock. When she is obliged, during the time of incubation, to leave her eggs in quest of food, she covers them up so artfully, that it is extremely difficult to discover them. On this occasion she is very tame, however wild and timid in ordinary; and it is said, will suffer herself to be lifted off the nest rather than move.

As soon as the young are hatched, they are seen running after the mother with great agility, though not entirely disengaged from the shell. The hen leads them forward into the woods, and shews them ants' eggs, insects, and the wild mountain berries, which, while young, constitute their only food. As they grow older their appetites grow stronger, and they then feed upon the tops of the heath, and the cones of the pine tree. In this manner they soon come to perfection: they are a hardy bird; and as their food lies every where before them, they would increase very fast, were it not for their enemies, not only human, but the eagle and other rapacious birds.

The cock of the wood is unknown in England, Wales, and Ireland; but he has, if we are to believe the account, lately been re-introduced into the Highlands of Scotland, in the neighbourhood of Inverness. They are met with in Denmark, Sweden, and indeed in most of the dark forests of the north; and were once tolerably numerous in the northern parts of Scotland.

The black cock (black grouse) is one of the finest birds offered to the attention of the sportsman: he is the first of the game species known in this kingdom, and is to be met with only in a few places in England, and not in great abundance. These birds are found in great abundance in some parts of the Highlands of Scotland, particularly from the bottom of Loch Lomond up as far as the Firth of Dornach. There are some beyond the Muckle Ferry, and they are to be met with even beyond the Marquis of Stafford's Mound, where the Little Ferry was seen a few years since; further, they are seen in the neighbourhood of Barrow Dale; but they will be vainly sought in the remoter parts of Sutherlandshire or in Caithness. There are also black cocks in some parts of the mountains of Cumberland; as well as on the hilly parts of Derbyshire and Staffordshire, in Devonshire, and also in the New Forest in Hampshire; some have lately been introduced on Delamere Forest in Cheshire, where they are rapidly increasing.

Black game breed on heathy moors, but are generally found in the vicinity of woods, and sometimes, though not often, in corn fields. They lie remarkably well at the commencement of the season (Au-

## G R O U S E

gust 20,) but soon become very wild, and will often fly to a great height.

The food is various, but consists principally of insects and mountain berries; and in winter the tops of the heath, as well as the cones of the pine tree, the seed of the alder, and corn when they can conveniently obtain it. It is said, but with what degree of truth we will not pretend to vouch, that cherries and pease are fatal to these birds. They perch or roost much in the same manner as the pheasant.

The *red grouse*, or *moor game*, is found upon most of the mountainous districts in the united kingdom.

This bird, as we have already observed, is larger than the partridge; the male weighing from nineteen to twenty-four ounces. The female is considerably less than the male; her colours are less vivid, and she has more of the white and less of the red feathers than the male.

The heathy and mountainous parts of the northern counties of England are in general stocked with these birds; but they abound in the Highlands of Scotland, and are very common in Wales and Ireland. They feed on insects, mountain berries, seeds, and the tender tops of the heath.

Red grouse pair very early in the spring, and the female lays from twelve to thirteen eggs, in a very simple nest, formed amongst the heath. The young leave the nest almost as soon as hatched, and continue to follow the hen till the severity of the winter sets in, when they unite in packs of twenty or thirty brace. They continue together in the greatest harmony till the approach of spring, when they feel the access of genial desire; the old females then, contrary to what is generally supposed, drive off the young cocks, and a general dispersion takes place: the males view each other with a jealous eye, and furious battles are the consequence.

Grouse are very difficult to be netted, owing to the straggling manner in which they lie, and their scattering on the approach of the sportsman, or on the least noise.

The care and stratagem of the female for the security of the young are wonderful, and similar to those of the partridge, to which article we refer the reader.

The *white grouse* or *ptarmigan*. This bird is something less than the red grouse. They moult on the approach of winter, and change their summer dress for one more calculated for the rigours of the climate in which they are destined to pass the winter; and, instead of having their feathers of many colours, they then become nearly white. By a wonderful provision, every feather also, except those of the wings and tail, becomes double, a downy one shooting out of the base of each; which, of course, gives an additional protection against the cold.—In the latter end of February, a new plumage begins to appear, first about the rump in brown stumps: the first rudiments of the coat they assume in the warm season, when each feather is single. In answer to inquiries made by Sir Joseph Banks, Dr. Solander, and some other naturalists, from

## G R O U S E

Capt. George Cartwright, who resided many years on the coast of Labrador, on the subject of the grouse changing their colour, he says, " I took particular notice of those I killed, and can aver, for a fact, that they get at this time of the year (September) a very large addition of feathers, all of which are white. In the spring most of the white feathers drop off, and are succeeded by coloured ones; or, I rather believe, all the white ones drop off, and they get an entire new set. At the two seasons they change very differently: in the spring beginning by the neck and spreading from thence; now they begin on the belly, and end on the neck."

Their feet, by being feathered entirely to the toes, are protected from the cold of the northern regions. Every morning they take a flight directly upwards into the air, apparently to shake the snow from their wings and bodies. They feed in the mornings and evenings, and in the middle of the day they bask in the sun.

About the beginning of October they assemble in flocks of one hundred and fifty or two hundred, and live much among the willows, the tops of which they eat. In December they retire from the flats about Hudson's Bay to the mountains, where, in that month, the snow is less deep than in the low lands, to feed on the mountain berries.

Some of the Greenlanders believe that the ptarmigans, to provide a subsistence through the winter, collect a store of mountain berries into some cranny of a rock near their retreat. It is, however, generally supposed, that by means of their long, broad, and hollow nails, they form lodges under the snow, where they lie in heaps to protect themselves from the cold. During winter they are often seen flying in great numbers among the rocks.

Though found in many of the mountains of the Highlands of Scotland, the ptarmigans are chiefly inhabitants of that part of the globe which lies about the arctic circle. Their food consists of the buds of trees (or rather perhaps the seed, as the writer is inclined to think, that neither the ptarmigan, nor any of the grouse tribe, devour the buds) mountain berries, and no doubt insects, of which all the ramifications of the grouse are remarkably fond. They are so stupid and silly, as often to suffer themselves without any difficulty to be knocked on the head, or to be driven into any snare that is set for them. When frightened, they fly off; but immediately alight, and stand staring at their foe. When the hen bird is killed, it is said, that the male will not forsake her, but may then also be killed with great ease. So little alarmed are they at the presence of mankind, as even to bear driving like poultry; yet notwithstanding this apparent gentleness of disposition, it is impossible to domesticate them; for, when caught, they refuse to eat, and always die soon afterwards.

Their voice is very extraordinary; and they do not often exert it but in the night. It is very rarely that they are found in Denmark; but by some accident one of these birds, some years ago, happened to stray within one hundred miles of Stockholm, which very much alarmed the common people of the neighbourhood; for, from its

PTARMIGAN.

or, White Grouse.

## G R O U S E

nightly noise, a report very soon arose, that the wood where it had taken up its residence was haunted by a ghost. So much were the people terrified, that nothing could tempt the postboys to pass the wood after dusk. The spirit was, however, at last happily removed, by some gentlemen sending their gamekeepers into the wood by moonlight, who soon discovered and killed the harmless ptarmigan.

Ptarmigans form their nest on the ground, in dry ridges; and lay from six to ten dusky eggs with reddish brown spots.

The usual method of taking these birds is in nets made of twine, twenty feet square, connected to four poles, and propped with sticks in front. A long line is fastened to these, the end of which is held by a person who lies concealed at a distance.—Several people drive the birds within reach of the net; which is then pulled down, and is sometimes found to cover fifty or sixty of them. They are found in such plenty in the northern parts of America, that upwards of ten thousand are frequently caught for the use of the Hudson's Bay settlement, between November and May.

They are taken by the Laplanders by means of a hedge formed with the branches of birch trees, and having small openings at certain intervals with a snare in each.—The birds are tempted to feed on the buds and catkins of the birch; and, whenever they endeavour to pass through the openings, they are caught.

Such is the account collected from natural historians, of the ptarmigan or white grouse; and as natural histories are very frequently put together by closet writers; or, in other words, by men of education, but with little practical knowledge on the subject, they are compelled to receive their accounts from others, and as many of the details are gathered from unlettered ignorance, so it is not to be wondered at that the delightful science of natural history is still so miserably defective.

The ptarmigan or white grouse is principally to be found in the most northern countries, amidst the snows of those inhospitable regions; but its constitution and habits are admirably adapted to the climate where it resides. It does not make its appearance farther south than the Highlands of Scotland, where it is found in tolerable plenty on the grey tops of most of the higher mountains. It is a laborious task to climb or ascend to those elevated regions where this bird is only to be found, though it is not difficult to shoot; yet as far as the writer has had an opportunity of observing (in the Highlands of Scotland), the ptarmigan will never "bear driving like poultry;" though it is not a bird by any means remarkably shy of human approach: but this, in all probability, arises from its so seldom coming in contact with man. It seems precisely of the same hue (at least in Scotland) as the grey rocks amongst which it is found; so much so indeed, that if, after shooting one, it be laid down, the similarity will scarcely fail to astonish the sportsman.

It is never seen (in Scotland) but on the tops of the mountains; and its colour so nearly resembling its abode, is beyond all question, its best security against rapacious birds, and the eagle in particular,

which seems for ever hovering over the heights where the ptarmigan is found. It is smaller than the red grouse, though its flesh presents a similar flavour; and from its never being observed in the valleys or lower grounds (in Scotland) it may be fairly presumed, that it can exist only in the colder regions, for which, nature, indeed, has admirably adapted it. In fact, from a due consideration of the ptarmigan, it would appear to be the grouse of the north, as the red grouse, or moor game, may be regarded as the grouse of the south; while its inferiority in size evidently arises from the frigid nature of its abode. It is said to be found not only on the mountains, but in the valleys also, in the colder regions near the pole; and hence we may justly conclude, that its never being seen in the lower grounds in the Highlands of Scotland, arises from the circumstance of the comparative mildness of the climate not suiting its hardy constitution.

**GUDGEON, THE,** is to be found in most of the English rivers: it delights most in gentle streams, with gravelly and sandy bottoms. Mr. Pennant records one caught near Uxbridge that weighed half a pound: though properly a river fish, they thrive amazingly in ponds which have gravelly scours, and are fed with brooks running through them. The compiler had gudgeons in a pond of this description, so large, that their average weight was five, and at most six to the pound: the shape of the body is thick and round; the irides tinged with red, the gill covers with green and silver: this fish is leather-mouthed; the lower jaw is shorter than the upper: at each corner of the mouth is a single beard; the back is dark olive, streaked with black; the lateral line straight; the sides beneath that, silvery, the belly white; the tail is forked, and, as well as the dorsal fin, is beautifully marked with black. The flesh of the gudgeon is so delicious, as to be called the fresh-water smelt, and is compared with the smelt in point of flavour.

Gudgeons spawn twice or thrice in a year; the chief time is the latter part of April, again during the summer, and in the beginning of autumn: about the end of spring they seek shallows, which they frequent all the hot months; but the rest of the year they are usually taken in deep water, upon a bottom sandy, with mud.

The gudgeon bites freely, and from the latter end of spring until autumn commences, in gloomy, warm days, from an hour after sun-rise to within the same space of its setting: during the rest of the year, the middle of the day, when it is warmest; for they do not take readily in cold weather, nor soon after spawning.

In angling for this fish in the shallows, the tackle must be very fine, a hook No. 7 or 8, a short rod and line, and a quill float; the bait should drag on the ground; they will take the small red-worm, gentles and blood-worms; the last is perhaps the best, and a rake (or the boat-hook, if fishing from a boat) should be kept frequently stirring the bottom. To this spot they assemble in shoals, expecting food from the discolouring of the water; and by now and then throwing in a few broken worms or gentles, they are also kept together, and sometimes great quantities are thus taken. They are apt to nibble at the bait; the angler ought not therefore to strike at the first biting: some use two or three hooks on the line. Such singular fascination had this fishing in one instance, that a clergyman, minister of Thames Ditton, who was engaged to be married to a daughter of the then bishop of London, overstaid the canonical hour, and the lady, justly offended at his neglect, withdrew her assent.

**GUN.** See the article FOWLING-PIECE.

**GUNPOWDER.** The first *fire* that was used in war occasioned as great (if not a more considerable,) alarm, as that caused by the explosion of gunpowder. It was called the *Greek fire*, and it is said to have been discovered in very ancient times. It was the invention of Calinicus, an architect of Heliopolis or Balbeck, who left the service of a Caliph, and brought the important arcanum to Constantinople in the reign of Constantine Pagonatus. That emperor forbade the art of making of it to be communicated to any except his own subjects, and the secret was long preserved: it was, however, at length known among the nations confederated

with the Byzantines. It is supposed to have been compounded of the gum of the pine and other resinous trees, reduced to powder with brimstone, to which were added naptha and other bitumens, and, according to some, the water of a fountain in the east, which had the property to amalgamate with these combustibles, and to render them more inflammable; but this last article seems hardly possible to have been included, as in that case it could have been only made where that water was to be had, whereas it was in use both all over Asia and in Europe. Anna Comena says it was composed of bitumen, sulphur, and naptha.

The *Greek fire* was employed A. D. 883, by Nicetas, the high-admiral of the eastern empire, who was sent by the Saracens of Crete with a navy to assault Constantinople: he attacked and utterly defeated the enemy, burning twenty of their ships by "the *Greek fire*."

Procopius, in his History of the Goths, calls it "Medea's oil," considering it as an infernal composition prepared by that sorceress. It is said to have been known in China, A. D. 917, three hundred years after Constantine Pagonatus, under the name of the "oil of the cruel fire;" and was carried thither by the Kitan Tartars, who had it from the king of Ou. This wonderful and destructive mixture twice preserved the metropolis of the Eastern Romans from the infidel armaments. The *Greek fire* is much spoken of in all the histories of the holy wars, as being frequently employed with success by the Saracens against the Christians. During the Crusades, and in the reign of Richard *Cœur de Lion*, we shall find, that it struck with dismay the most intrepid Christian knights, until a method of extinguishing it was discovered by the French. By the following description of it, given by Joinville, who was an eye-witness, it had somewhat the appearance of the *iron rockets* still used in India: he says it was thrown from the bottom of a machine called a *petrary*, and that it came forward as large as a barrel of verjuice, with a tail of fire issuing from it as big as a great sword, making a noise in its passage like thunder, and seeming like a dragon flying through the air; and from the great quantity of fire it threw out, giving such a light, that one might see in the camp as if it had been day. Such was the terror it occasioned among the commanders of St Louis's army, that Gautier de Cariel, an experienced and valiant knight, gave

it as his advice, that so often as it was thrown, they should all prostrate themselves on their elbows and knees, and beseech the Lord to deliver them from that danger, against which he alone could protect them: this counsel was adopted and practised; besides which, the king being in bed in his tent, as often as he was informed that the *Greek fire* was thrown, raised himself in his bed, and with uplifted hands thus besought the Lord; "Good Lord God, preserve my people!" But the great terrors it occasioned, the effects of this fire do not seem to justify, as a mode had been found of quenching it. We are told, some of their castellated cats (a covered shed, occasionally fixed on wheels, and which had crenelles and chinks, from whence the archers could discharge their arrows; it was used for covering soldiers employed in filling up the ditch, preparing the way for the movable tower, or mining the wall; sometimes under the cover of this machine the besiegers worked a small kind of ram,) were set on fire, but the flames were extinguished. The *Greek fire* was thrown thrice in the night from the petrary, and four times from a large cross-bow: the blaze lighted by this composition was inextinguishable by water. Geoffry de Vinesauf, who accompanied Richard I. to the crusade, says of it, "with a pernicious stench, and livid flame, it consumes even flint and iron, nor could it be extinguished by water; but by sprinkling sand upon it the violence may be abated, and vinegar poured upon it will put it out. To these, some add urine, and even oil."

From other descriptions it appears, this composition was of an unctuous and viscid nature, sticking to the objects against which it was directed. In land engagements and sieges, it was projected by the machines of the times, and at sea by hand, enclosed in vessels or phials, in which it was also kept and transported; it was likewise sometimes fastened to the heads of arrows: sea water, instead of quenching, seemed to give it new violence and activity.

Both parties used the *Greek fire* at the siege of Acre, A. D. 1190, and Father Daniel says, "this wild fire was not only used in sieges, but even in battles, and that Philip Augustus, king of France, having found a quantity of it prepared in Acre, brought it with him to France, and employed it at the siege of Dieppe, for burning the English vessels in that harbour. At several other sieges in France,

it was also used; and an engineer, named Gaubert, a native of Mante, acquired the art of making it, which luckily for mankind, has been since lost." A composition something of the same nature was some years since invented by a chemist in this country, and who has an annual allowance so long as it shall remain a secret; our government being unwilling to increase the destruction and cruelty of war: a like discovery was made formerly in France or Holland, and for the like reason suppressed. It was supposed that this was what Earl Stanhope referred to, when he said in the House of Lords, "that the French were not only in possession of a secret respecting this unquenchable fire, but meant to practise it against our navy to its certain destruction." Notwithstanding, they do not appear to be fond of coming close enough to our fire of common gunpowder, to enable them to apply any of this supposed more destructive material.

Greek fire was used long after the introduction of fire arms, particularly in sieges. When the Bishop of Norwich besieged Ypres, A. D, 1383, the garrison is said, by Walsingham, to have defended themselves so well with stones, arrows, lances, *Greek fire*, and certain engines called *guns*, that they obliged the English, to raise the siege with such precipitation, that they left behind them their *great guns*, which were of inestimable value. A great part of that army was soon after besieged in the town of Burburgh, by the French, who threw such quantities of *Greek fire* into it, that they burned a third part of the town, and obliged the English to capitulate.

Although the invention of gunpowder, with its application to fire-arms, may be ranked among the most important discoveries, yet the date of that invention, with the name of the person to whom mankind are indebted for it, are both equally unknown. From the number slain in engagements previous to its introduction, what, at first view of its fatal effects, might be deemed an additional and severe scourge, has rather proved beneficial to the human race, by reducing the destruction of the species in battle within narrower limits. Formerly, when men engaged *hand to hand*, they were so intermingled, that the only criterion of victory was, the having no more of the enemy to kill: the duration of sieges has also been considerably shortened since the use of gunpowder and artillery, by which the lives of many

millions have been saved, who would otherwise have perished by hardships or disease, commonly in sieges more fatal than the sword, and in providing man with increased power over the animal world, and thus multiplying the catalogue of his food, the advantages derived from gunpowder are eminent.

The common story respecting the invention of gunpowder and artillery is thus related: about the year 1320, one Bartholdus Schwartz, a German monk, and student in alchymy, (a pursuit then much in fashion,) having, in the course of his experiments, mixed saltpetre, sulphur, and charcoal in a mortar, and partly covered it with a stone, it somehow took fire, and blew the stone to a considerable distance: thus, by one accident, furnishing the hints for making gunpowder, its force, and a piece of ordnance for using it: and it is worthy of observation, that *stones* are said to have been thrown from mortars long before *point blank* shooting was attempted: possibly this story may be true; but it does not at all follow from thence, that gunpowder was not *before known*, the same discovery having been frequently made by different persons engaged in the same study.

Many modern writers carry the invention of gunpowder, and even its application to artillery, back to very remote antiquity. The ingenious translator of the *Gentoo Laws*, finds *fire arms*, *gunpowder*, and *cannon*, mentioned in that code, supposed at least coeval with Moses.

Our countryman, Friar Bacon, whose works were written at Oxford about the year 1270, fifty years before the supposed invention by Schwartz, has expressly named the ingredients of gunpowder as a well-known composition used for recreation, and describes it as producing a noise like thunder, and flashes like lightning, but more terrible than those produced by nature, and adds, this might be applied to the destruction of an enemy by sea and land: Bacon acquired this composition from a treatise on artificial fire-works, written by one Marcus Græcus; the manuscript is still extant, and is quoted by the Rev. Mr. Dutens, in order to prove that gunpowder was known to the ancients; the composition therein prescribed is, two pounds of charcoal, one pound of sulphur, and six pounds of saltpetre, well pounded and mixed together in a stone mortar; this is a better mixture for powder than many late in use.

Bishop Watson, in his *Chemical Essays*,

remarks, that the history of the discovery of gunpowder is involved in much obscurity; the most ancient authors differing from each other in their accounts of this matter, and many of them confounding two distinct inquiries:—viz. the discovery of the composition of gunpowder; and the discovery of finding out the means of applying it to the purposes of war.

In 1378, is the first authentic mention of the lately invented instruments of death to be found; for then Richard II. sent to Brest great quantities of saltpetre, sulphur, and charcoal, together with two greater and two lesser engines called cannons, and 6,000 stone bullets.

In several accounts of military stores during the reign of Edward VI. and Elizabeth, there are large quantities of serpentine powder.

The making of gunpowder after the most ancient manner:—

Anno 1380, saltpetre, brimstone, charcoal, equal parts.

Anno 1410, saltpetre three parts, brimstone two parts, charcoal two parts.

Anno 1480, saltpetre eight parts, brimstone three parts, charcoal three parts.

Anno 1520. The making best powder, saltpetre four parts, charcoal one part, brimstone one part.

Anno 1647. The best sort now made, saltpetre six parts, brimstone one part, charcoal one part.

The musket powder is now commonly made of saltpetre five parts, brimstone one part, charcoal one part.

The cannon powder, saltpetre four parts, one part charcoal, one part brimstone.

The Bishop of Landaff, in his essay on the Composition and Analysis of Gunpowder, states, “that in the proportion in which they are combined, the manner of mixing, the goodness of the ingredients, and the drying of the powder after being made, its strength and excellency consist. Saltpetre, in its crude state, whether it be brought from the East Indies or made in Europe, is generally, if not universally, mixed with a greater or less proportion of common salt: now a small portion of common salt injures the goodness of a large quantity of gunpowder; hence the very finest saltpetre becomes necessary to be used in its formation. The purest sulphur is that sold under the name of flowers of sulphur; but the roll sulphur being much cheaper than the former, and being also of a great degree of purity, it is the only sort which is used in the manufac-

turing of gunpowder. With relation to the charcoal, it has been for the most part believed that the coal from soft and light woods was better adapted than the hard and heavy ones to the making of gunpowder; thus Evelyn says of the hazel, that ‘it made one of the best coals used for gunpowder, being very fine and light, till they found elder to be more fit.’ An eminent French chemist (M. Baume) has shewn from actual experiment, that this opinion in favour of coal from light wood is ill founded: he affirms, that powder made from lime tree coal, or even from the coal of the pith of the elder tree, is in no respect preferable to that made from coal of the hardest woods, such as guiacum and oak. This remark, if confirmed by future experience, may be of service: as it is not always in the power of gunpowder makers to procure a sufficient quantity of the coal of soft wood.

“The mixture of the materials of which gunpowder is made should be as intimate and uniform as possible; for in whatever manner the explosion may be accounted for, it is certain that the three ingredients are necessary to produce it. In order to procure this accurate mixture, the ingredients are previously reduced into coarse powders, and afterwards ground and pounded together, till the powder becomes exceedingly fine; and when that is done the gunpowder is made. But, as gunpowder, in the state of an impalpable dust, would be inconvenient in its use, it has been customary to reduce it into grains, by forcing it, when moistened with water, through sieves of various sizes.

“The necessity of a complete mixture of the materials, in order to have good gunpowder, is sensibly felt, when such as has been dried, after being accidentally wetted, is used. There may be the same weight of the powder after drying that there was before it was wetted; but its strength is greatly diminished, on account of the mixture of the ingredients being less perfect. This diminution of strength proceeds from the water having dissolved a portion of the saltpetre (the other two ingredients not being soluble in water); for upon drying the powder, the dissolved saltpetre will be crystallized in particles much larger than those were which entered into the composition of the gunpowder, and thus the mixture will be less intimate and uniform than it was before the wetting. This wetting of gunpowder is often occasioned by the mere moisture of the atmosphere. Great complaints

were made concerning the badness of the gunpowder used by the English, in their engagement with the French fleet off Grenada, in July, 1779; the French having done much damage to the masts and rigging of the English, when the English shot would not reach them. When this matter was inquired into by the House of Commons, it appeared that the powder had been injured by the dampness of the atmosphere; it had concreted into large lumps, in the middle of which the saltpetre was visible to the naked eye. If the wetting of gunpowder has been considerable, it is rendered wholly unfit for use; but if no other foreign substance has been mixed with it, except fresh water, it may be made into good gunpowder again, by being properly pounded and granulated. If the wetting has been occasioned by salt-water, and that to any great degree, the sea salt, upon drying the powder, will remain mixed with it, and may so far vitiate its quality, that it can never be used again in the form of gunpowder. However, as by solution in water, and subsequent crystallization, the most valuable part of the gunpowder, namely, the saltpetre, may be extracted, and in its original purity, even from powder that has been wetted by sea water, or otherwise spoiled, the saving damaged powder is a matter of national economy, and deservedly attended to in the elaboratory of Woolwich.

“The proportions,” continues Dr. Watson, “in which the ingredients are combined together are not the same in different nations, nor in different works of the same nation, even for powder destined to the same use. It is difficult to obtain from the makers of gunpowder any information upon this subject: their backwardness arises not so much from any of them fancying themselves possessed of the best possible proportions, as from an affectation of mystery, common to most manufacturers, and an apprehension of discovering to the world that they *do not*

ENGLAND.	FRANCE.	SWEDEN.
Saltpetre 75lb. ...	75lb. ...	75lb. ...
Sulphur 15 ...	9½ ...	16 ...
Charcoal 10 ...	15½ ...	9 ...
100	100	100

“Several experiments have been made in France to ascertain the exact proportions of the several ingredients which would produce the strongest possible powder, and the result has been in favour of

*use so much saltpetre as they ought to do,* or as their competitors in trade really do use. Saltpetre is not only a much dearer commodity than either sulphur or charcoal, but it enters also, in a much greater proportion, into the composition of gunpowder than both of those materials taken together; hence there is a great temptation to lessen the quantity of the saltpetre, and to augment that of the other ingredients; and the fraud is not easily detected, since gunpowder, which will explode readily and loudly, may be made with very different quantities of saltpetre.

“Baptista Porta died in the year 1515: he gives three different proportions for the making of gunpowder, according as it was required to be of different strength, the quantities of the several ingredients contained in one hundred pounds weight of each sort of powder.

	WEAK.	STRONG.	STRONGEST.
Saltpetre	66⅔lb. ...	75lb. ...	80lb.
Sulphur	16⅔ ...	12½ ...	10
Charcoal	16⅔ ...	12½ ...	10
	100	100	100

“It is somewhat remarkable, that in these three powders the sulphur and charcoal are used in equal quantities. Cardan died about sixty years after Baptista Porta, and during that interval the proportions of ingredients of gunpowder seem to have undergone a great change. Cardan’s proportions are expressed as follows:

	GREAT GUNS.	MIDDLE SIZED.	SMALL.
Saltpetre	50lb. ...	66⅔lb. ...	83⅓lb.
Sulphur	16⅔ ...	13⅓ ...	8⅓
Charcoal	33⅓ ...	20 ...	8⅓
	100	100	100

“For great and middle sized guns, we see a much greater proportion of charcoal than of sulphur was here used: at present it is in most places the reverse; or at least the charcoal no where exceeds the sulphur. The proportions are as under, for the best kind of gunpowder in England, France, Sweden, Poland, and Italy.

	POLAND.	ITALY.
Saltpetre	80lb. ...	76½lb.
Charcoal	12 ...	12½
Sulphur	8 ...	12½
	100	101½

And from hence it appears that, in a certain weight of saltpetre, the powder

would produce the greatest effect when the weight of the charcoal was to that of the sulphur as three to one. On the other hand, experiments are produced from which it is to be concluded that in a certain weight of saltpetre the best powder is made when the sulphur is to the charcoal as two to one. From these different accounts it seems as if the problem of determining the very best possible proportions was not yet solved.

"In drying gunpowder, after it is reduced into grains, there are two things to be avoided, too much and too little heat. If the heat is too great, a part of the sulphur will be driven off, and thus the proportions of the ingredients being changed, the goodness of the powder, so far as it depends upon that proportion, will be injured. In order to see what quantity of sulphur might be separated by a degree of heat not sufficient to explode it, I took," says Dr. Watson, "twenty-four grains of the powder marked FF in the shops, and placing it on a piece of polished copper, I heated the copper over the flame of a candle; the gunpowder soon sent forth a strong sulphureous vapour, and when it had been dried so long that no more fume or smell could be distinguished, the residue weighed nineteen grains, the loss amounted to five grains. The remainder did not explode by a spark like gunpowder, but, like a mixture of saltpetre and charcoal, and it really was nothing else, all the sulphur having been dissipated. Gunpowder was formerly dried by being exposed to the heat of the sun; and this method still obtains in France, and in some other countries: afterwards a way was invented of exposing it to a heat equal to that of boiling water; at present it is most generally in England dried in stoves, heated by great iron pots; with any tolerable degree of caution, no danger of explosion need be apprehended from this method. All the watery part of the gunpowder may be evaporated by a degree of heat greatly less than that in which gunpowder explodes, that degree of heat having been ascertained by some late experiments to be about the six hundredth degree on *Fahrenheit's* scale, in which the heat of boiling water is fixed at two hundred and twelve. There is more danger of evaporating a part of the sulphur in this mode of drying gunpowder than when it is dried by exposure to the sun.

"The necessity of freeing gunpowder from all its moisture is obvious from the

following experiment, which was made some years ago before the Royal Society. A quantity of gunpowder was taken out of a barrel and dried with a heat equal to that in which water boils, a piece of ordnance was charged with a certain weight of this dried powder, and the distance to which it threw a ball was marked. The same piece was charged with an equal weight of the same kind of powder, taken out of the same barrel, but not dried, and it threw an equal ball only to one half the distance. This effect of moisture is so sensible, that some officers have affirmed that they have seen barrels of gunpowder which were good in the morning, but which became (by attracting, probably, the humidity of the air) entirely spoiled in the evening. To keep the powder dry, by preventing the access of the air, it has been proposed to line the barrels with *tin foil*, or with thin sheets of *lead*, as tea boxes are lined. Would it not be possible," asks Dr. Watson, "to preserve powder free from moisture, and from the loss of a part of its sulphur in hot climates, by keeping it in glazed earthen bottles, or in bottles made of copper or tin, well corked? The disposition to attract the humidity of the air varies in different sorts of powder; it is the least in that which is made from the purest saltpetre. Pure saltpetre, which has been dried as gunpowder is dried, does not become heavier by exposure to the atmosphere; at least, so far as my experiments have informed me, not amounting to above one seventy-second part of its weight. I rather think," continues Dr. Watson, "that it does not acquire any increase of weight; however, in order to judge with more certainty concerning the effect of sea salt when mixed with saltpetre, in attracting the humidity of the air, I made the following experiment: five parts of pure saltpetre, in powder, were exposed for a month to a moist atmosphere, but I did not observe that the saltpetre had gained the least increase of weight; for the same length of time, and in the same place, I exposed four parts of saltpetre mixed with one of common salt, and this mixture had attracted so much moisture, that it was in a state of fluidity."

For ascertaining the strength of powder, gunsmiths generally make use of an instrument, which, I believe, is called a *trier*, and from which may be obtained tolerably accurate results: I prefer the fowling-piece for this purpose: by adjusting the charge very exactly, and firing at paper, many sheets in thickness, and at

given distances, much satisfaction may be obtained, not only as to the quality of the powder, but of the manner in which the gun throws the shot.

**GWINIAD.** It is found, according to Pennant, in one of the lakes of Ireland, Lough Neagh, where it is called the pollen; in Loch Mabon, in Scotland, where it is termed the vangis; and the Scotch have a tradition that it was there first introduced by their beauteous Queen, the unhappy Mary Stuart; and as in her time the Scotch court was much Frenchified, it seems likely that the name was derived from the French *vendoise*, a dace, to which a slight observer might compare it from the whiteness of the scales: the British name, gwiniad, or whiting, was bestowed upon it for the same reason.

It is a native of the lakes in Cumberland; and in Wales in that of Pemble Meer, or Llynteged, near Bala, in Merionethshire. In the lakes of the Alpine parts of Europe, in those of Switzerland, (in that of Geneva it is named *ferra*,) Savoy, and Italy, of Norway, Sweden, and Lapland, (where Schæffer asserts they are caught of the weight of ten or twelve pounds,) this fish is an inhabitant. It is, continues Mr. Pennant, gregarious, and approaches the shores during spring and summer in such vast shoals as to prove, in many places, to the poor of inland counties, as great a relief as the return of the herring is to those who dwell upon the coasts; and he recites an instance of an Ulles-Water fisherman who took between seven and eight thousand at one draught: it is there called *schelly*, a name which the inhabitants of Cumberland give also to the chub, from its being a scaly fish.

It has long since been observed in Camden, that the gwiniad never wanders into the Dee, nor does the salmon ever venture into the Bala lake; and, generally speaking, this is the case; but, by accident, the first has been known to stray as far as Landrillo, six miles down the river, and a salmon has now and then been found trespassing in the lake.

The late Honourable Daines Barrington remarks upon this fish, that it is universally supposed (and even by Lhwyd, in his additions to Camden's *Britannia*) salmon are never caught in the lake of Bala, although they are frequently taken in the river Dee, just below where it issues from the lake, whilst the contrary is observed with regard to the gwiniad, which is conceived to be a fish peculiar to the lake; but, says Mr. B. I happened to see a salmon of

about fifteen pounds caught in the lake, at least two hundred yards above the bridge through which the Dee issues; and, although I never saw the gwiniad taken in that river, yet was I most authentically informed that several were caught, within three years, as low down as Landrillo, nearly six measured miles from the lake of Bala; and with respect to the gwiniads being only in this lake, I can myself flatly contradict this notion, as the first parcel of fish which I happened to see in the market of Penrith, in Cumberland, were of this sort, and were brought from Ulles-Water, about four or five miles from thence.

One very striking mark in this fish, which cannot but be attended to by those who are not naturalists, is, that they have the ventral fins of a very deep blue, and the belly at most seasons is marked with blue spots; which, concludes Mr. B. is what I do not recollect in any other fish of this island.

According to Mr. Pennant, the gwiniad is an insipid fish, and must be soon eaten, as it will not keep; and those that choose to preserve, salt them: (Schæffer represents them as being of an eminently fine luscious taste, and known in Lapland and Sweden by the name of *sijk*:) the largest Mr. P. ever heard of weighed between three and four pounds; that from which he took his description was eleven inches long, and its greatest depth three. The head is small, smooth, and of a dusky hue; the eyes very large, and the pupil of a deep blue; the nose blunt at the end; the jaws of equal length; the mouth small and toothless; the covers of the gills silvery, powdered with black; the back is rather arched, and, as far as the lateral line, glossed with a deep blue and purple colour, but towards the line assumes a silvery cast, tinged with gold, beneath which those colours entirely prevail; the belly is a little prominent, and quite flat on the bottom: the first dorsal fin is placed almost in the middle; the second is thin, transparent, and not distant from the tail; the ventral fins in some are of a very fine blue, in others as if powdered with blue specks; the ends of the other lower fins are tinged with the same colour; the tail is very much forked; the scales are large, and adhere close to the body. Their spawning season in Llynteged is in December. They are taken in nets, but never by any bait, keeping on the bottom of the lake, and feeding on small shells, and the leaves of water gladiol, a plant peculiar to these mountain lakes.

THE JOCKEY'S HACK.

# H

**HACK, THE.** From a superficial glance at the subject, it might be hastily supposed, that hacks were every where to be met with; and such is the case: but, of all descriptions of the horse, I am of opinion that a thorough good hack is the most difficult to procure. A horse of this description should go well in all his paces, and be perfectly free from stumbling; and in this case, as in that of the hunter, a certain combination of figure and form are indispensably necessary for the satisfactory accomplishment of the object in view. Let it not, however, be hastily supposed, that the form and character of the hunter are precisely those which are requisite in the hack; the cases are very different; and it rarely happens that a hunter, however excellent his qualities in the field, becomes a good roadster. Further, a horse used to harness, a gig horse, for instance, how safe soever he may be in his going, is seldom, if ever, pleasant to ride. By leaning against the collar, he is induced to accommodate his paces accordingly; and thus, if used as a saddle horse, the rider will soon perceive, that he is any thing rather than a pleasant hack. A horse may be used (and sometimes is) for hunting, running in a gig, and as a hack; if he excels in *one* of these, it is as much as can be reasonably expected: he cannot be superior in all.

In a hack, I am an advocate for a large portion of blood; nor would I refuse a hack as highly bred as possible, supposing his form and mode of going were such as met my approbation. But I must candidly confess, that the best hacks which I have ever seen, have not been thorough-bred, though they have evidently manifested very considerable breeding. What indeed is understood by the term blood, is a quality of which, in my opinion, scarcely any horse should be destitute; since it gives the animal superior courage, strength, activity; and, even when *over-marked*, enables him to regain his wonted health and vigour in a short space of time. It is well known to persons conversant with the subject, that horses with plenty of breeding, when worked to a stand still, much sooner recruit, or come round again, than those of inferior blood.

From fourteen hands, three inches, to fifteen hands, two inches, may be considered as the hack standard. The hack should be a compact, rather than a *lengthy*, horse, free from vice of every description, and remarkably sure-footed: a stumbling hack places his rider's neck in continual danger. The first and most essential point in a hack is the form of the shoulders: if they are not placed in the true declining position—if they do not possess sufficient slope, the animal can never be safe. The reason is evident: an upright or straight shouldered horse carries the saddle too forward, and thus the weight of the rider, by being placed too near, or too much over, the fore legs, prevents, as it were, the free use of them; with his burden thus placed upon him, the horse is incapable of raising his fore feet sufficiently high; his toe is consequently liable to strike, or catch, the most trifling inequality of the road, he stumbles, is less able to recover himself from his load being placed too forward, and

is therefore very likely to come down or fall. Some horses are apt to go *too near*, as it is called, that is, not to lift their fore feet sufficiently high: these will frequently catch and stumble; but, if the form of their shoulders be correct, they will seldom fall:—the reason is obvious—the weight is placed further back, they have thus the free use of their fore legs, and are enabled to recover themselves. Thorough-bred horses will often go very near; and, for the purposes of the course, it is a great recommendation, as by it they acquire an acceleration of speed; but in a hack it is an evident draw-back, however great his merits may be in every other respect. It is somewhat difficult to give a satisfactory reason why blood-horses almost uniformly manifest a disposition to go too near, since their shoulders are generally well placed. Originally they are descended from the Arabian steed, which is a *daisy cutter* by nature as well as habit:—the Arabian horse, in his native country, has to traverse sandy deserts—speed is the principal object of his master; and as the surface of the ground over which he passes is the very opposite of that to which an English hack is accustomed, and offers little or no impediment to closeness of going, he is habituated to it accordingly, and the propensity is propagated from one generation to another.

A hack should be a compact well-formed animal, bony, with good legs and feet, thighs long, quarters wide and well set in, deep ribs, shoulders well thrown back, long muscular arm, short from the knee to the ground, legs straight, neck long rather than short, and a well formed head, dropping prettily at the end of it. Full clear eye, forehead broad, nostrils wide (See the article HUNTER). A ewe-neck presents an unsightly appearance: well-bred horses, however, are frequently seen inclining to the ewe-neck: *Fleur de Lis*, for instance, one of the finest mares in England, and unquestionably a very superior racer, is ewe-necked; I have seen many excellent horses thus formed; and therefore should not reject a hack, otherwise eligible, because he happened to be rather ewe-necked.

I have already observed that a hack should be good in all his paces, but as there are some persons who prefer the walk, others the trot, and others the canter—in procuring a hack, a person should endeavour to suit his own taste or inclination in this respect. Some elderly persons, and a few others, are satisfied with the walk, and these should consequently seek for an animal who excels in it: horses are to be found that will walk five or perhaps six miles an hour; and good walkers I have often found safe goers. Those who prefer the trot, should seek for a horse whose form of trotting is safe, rather than fast; one that lifts his feet up well, and trots out fairly: a horse of this description is very safe to ride, and will generally be found to be quite swift enough for all ordinary purposes. If the canter be preferred, a short compact horse should be chosen for the purpose.

It will be here necessary to remark, that some horses in their slow paces, and particularly in their walk, will loll upon the bridle, and become consequently very heavy in hand; than which nothing can be more unpleasant; and, what is worse, animals of this description are very liable to fall, and that too very suddenly. A horse

seldom falls when going fast. A hack (and indeed all descriptions of horses;) should be light in hand, in which case, he seldom fails to have what is called a good mouth.—Whoever purchases a horse with which he has not been previously well acquainted, ought to ride him a few miles, in order to ascertain whether he is a “*tumble down*,” restive, or has contracted any other vicious habits. By riding slowly, with a slack bridle, and in a careless manner, if the horse have a propensity to stumbling, it will soon be discovered. Many horses have a great aversion to meeting a stage coach, a large caravan, or any large vehicle, and such a circumstance cannot fail to be unpleasant and alarming to a timid or unskilful rider. Not that I should reject a horse merely on this account, as, unless the animal is old, and the habit absolutely and inveterately confirmed, it is a defect not very difficult to remedy.—Generally speaking, those persons whose business or avocation in life it is to attend horses, are seldom remarkable for education or intelligence; and if they possess the power or faculty of reflection, they seldom exercise it in a correct or philosophical manner. A young horse, before he is backed or ridden, is unaccustomed to a turnpike road, and consequently when first brought upon it, the vehicles which he there meets are new to him, and the manner in which they approach generally alarms him (he seldom testifies any symptoms of alarm when carriages are moving in the same direction as himself—not nearly so much even on passing them). When he comes to pass the object which had already excited his fears, he presses to the extreme side of the road, in order to place himself as far as possible from the object of his alarm, and rushes by or past it; or, instead of this, on approaching it turns about, and refuses to pass altogether. An ignorant groom or horse-breaker immediately applies the whip and spurs most unsparingly, which is making bad worse; if he succeed in forcing the horse in the wished-for direction, it is at the expense of his fears; and when a similar object presents itself, the animal is still more alarmed, from the excessive punishment which he received before, and the same scene is played over again, most likely with increased violence on both sides. Thus, on the approach of whatever has originally alarmed the horse, he immediately recollects the punishment he has endured, expects a repetition of it; his fears increase, rather than subside, and the habit, in a short time, may perhaps be difficult to remove, even when proper means are adopted for the purpose. Now, if instead of the whip and spur, soothing, friendly words, caresses and mildness had been substituted, though the animal might not have met the object of his alarm with indifference, his resistance would have been much less violent; and a few repetitions would have removed it entirely.

Whenever a horse manifests alarm at any object, whether stage coach, caravan, windmill, &c. he should never be violently pressed to face it: he should be coaxed, patted, and not forced too near the object which causes his terror, on the first occasion. He should be accustomed to the sight as much as possible, and by gentle, but firm, treatment (for he must not be suffered to avoid it altogether;) he will soon be brought to face it with indifference. I had a horse, some

few years ago, which, the first time I happened to be passing near a windmill, turned suddenly round, and galloped back with me for several hundred yards before I could pull him up. The horse was a good tempered creature, but high spirited, and it was not without great difficulty I could induce him to approach within about thirty yards of the mill. It was evident that severe punishment had been administered on some former occasion. However, the following morning I rode the same way ; and being prepared for the business, I took care he did not turn and carry me back as before. By kind treatment, I induced him to approach much nearer, and to remain in that position for some minutes : after a few lessons of this sort, I was enabled to ride him as near the mill as the sails would allow, and for the three years following, while he remained in my possession, he uniformly passed a windmill with as much indifference as his rider.

I should never advise any person to purchase a restive horse ; and this vicious propensity, which arises from a base, cowardly disposition, is easily discovered, when the animal is mounted by a stranger. Many restive horses will go quietly enough with those who are perfectly master of them ; but the moment they are mounted by a stranger they prepare for battle. Some of these animals will go pleasantly enough, even with a stranger, provided they are ridden but a short distance from the stable ; or, if in a town, the ride be confined to the town ; but when the animal is taken farther than he wishes (suspecting a journey is the object, as restive horses have an inveterate antipathy to work ; ) he may be perceived to stare, place his ears in a forward direction, will breathe very hard or loud, and will appear to labour under some degree of alarm. He is looking out for his object ; and will seldom fail to stop at the first stable, barn, house, or building, or any thing else which he approaches. He will turn suddenly round and go back, he will stand still, or perhaps attempt to run into the yard, if there be one ; or into the stable, if the door be open ; or force himself against the wall or gate post, and perhaps break the rider's leg. If you attempt to fight with him on these occasions (and gentle means are out of the question ; ) he will be found prepared for the contest.—With one fore foot placed in advance, on the side on which his mouth is the hardest (and all horses have one side harder than the other) he will be prepared to resist all attempts at pulling him round. The best method under such circumstances, is to pull the opposite rein suddenly, pull him quite round, and continue pulling him completely round three or four times as quickly as possible, which makes him giddy, throws him off his guard, and completely confuses him. As soon as three revolutions have been completed, his head should instantly be placed in the direction in which it is wished to proceed, and, at the same moment, the spurs and whip applied in the most liberal manner possible. He will, of course, gallop for some time ; and, if the nature of the road will allow, he should be compelled to gallop considerably further than his own disposition would induce him to go. The greater part of restive horses may be compelled to abandon this highly dangerous propensity by the method just described, and in a much shorter time

than is generally supposed; but they are never to be trusted, and seldom fail to try for mastery with every strange rider that may happen to mount them. Moreover, there are horses to be met with so inveterately restive, as to be incurable—they will rear most alarmingly, a vice dangerous in the highest degree; which is seldom totally eradicated, but may be partially suppressed, by those who are masters of the science of equitation.

Yet, it is but fair to remark, that there are horses, which, from a little obstinacy of disposition, are apt to manifest a wish or will in opposition to that of their rider, which are, nevertheless, valuable animals. Ten years since, I purchased a little black Irish horse, which I rode very pleasantly for some weeks; but happening to take a journey of some distance, when on my return, a few miles from home, I wished to call on a friend, and for that purpose attempted to turn the horse down a lane which led to the house, in a different direction from my house, and consequently from the horse's stable. He was perfectly conscious of this; for he placed his off fore foot in advance, and immediately assumed a tone of disobedience. I instantly pulled the opposite rein of the bridle, twisted him round three or four times, placed his head in the direction I wished to proceed; at the same time, I applied the steel and the lash most freely, and we thus went along as fast as the horse could gallop for about half a mile; when he went forward as quietly as possible. This could scarcely be called vice: the horse was anxious to get to his own stable, and was aware the road I wished to take did not lead to it.—He never made but one more attempt of the same kind; and was, on the whole, a very good horse.

Professed horse dealing is that kind of business in which neither candour nor honour is to be expected: deception is studied by horse dealers as a science; and whatever act of dishonesty may be committed by one of this knowing fraternity, the transaction is regarded by the author of it as very clever; he laughs in his sleeve, and takes much merit to himself for his own dexterity and cunning; while the world view the matter as relating to the man's avocation, and, generally speaking, he is not regarded as dishonest on that account. Indeed, it may be further remarked, that most persons (not including dealers) who have horses to dispose of allow themselves a very wide latitude, or rather perhaps a very considerable stretch of conscience; and, although in other matters they would shudder at the idea of being guilty of any thing like dishonesty, yet, in the sale of a horse, would not hesitate to resort to the most culpable equivocation, if not to positive and deliberate falsehood.

Under such circumstances, therefore, it behoves those who wish to purchase a horse, and are incapable of forming a good opinion for themselves, to be very circumspect in the business. A horse may be returned, it is true, if warranted sound; dealers are also ready enough to give a warranty: yet if it becomes necessary to return the horse, as the seller had, in all probability, been guilty of studied falsehood in ridding himself of the animal, he resorts to the same means, and even to false swearing, for the purpose of retaining the

money which he has received for him. For my own part, in my horse dealing transactions, I neither require, nor give, a warranty. I never purchase a horse till I have ridden him sufficiently to satisfy myself that he will suit me. In the sale of a horse, I allow a similar latitude. By this method, I avoid every thing in the form of litigation: yet I by no means offer my system as an example for others, since a regular warranty must, after all, operate as a sort of protection for the unskilful in horse flesh.

But to return to the subject of vice in horses, and those tricks which are almost daily in practice by horse dealers. Having made all the requisite observations respecting unsafe goers, those which are said to *shy* on the road, and on restive horses, I have further to remark, that there are several other circumstances or cases incident to the business of purchasing a horse, which require consideration. A broken winded horse is very easily discovered, even by the most indifferent judge, when galloped a short distance, unless means are adopted to prevent it. The dealers in what are called *screws* for the purpose of hiding the defect of broken wind, give the animal bacon fat, (most likely any kind of fat or animal oil would answer the same purpose,) to which some of them add shot or lead, which, it seems, will enable the horse to breathe for twenty-four hours without exhibiting those very obvious and well-known symptoms which denote the disease. Again, if a horse is a kicker, or be otherwise vicious, when approached or handled, he is dosed with opium, the effect of which is too well known to need a description in this place.

Horses with very delicate mouths should be ridden in a plain snaffle, unless they are given to stumbling, in which case the curb is to be recommended—a powerful curb upon a hard mouthed horse.

Cobs and ponies may be appropriately enough placed under the present head, since they are very generally employed as hacks. Many of what are called cobs, are perhaps the most generally useful of any of the horse tribe. They may be regarded as “*large horses in a little compass*,” and, when they possess the gift of going well, make not only good hacks, but may be applied to almost any purpose.

Ponies are useful creatures, and occasionally create surprise by the long journies which they perform; but they cannot be so pleasant in their paces as horses with a proper large stride. They are best calculated for children.—Timid ladies are partial to riding on ponies; they would be more securely and pleasanter carried on good sized horses.

The *Lady's Pad* is seldom required to be a powerful animal; but, above all horses, should be safe and surefooted, with a mouth as delicate as possible: and, in order to accomplish these objects, the horse should have his mouth properly made, and he should then be ridden over the most uneven ground possible with the bridle lying loose upon his neck: he would most likely fall at first, but would soon learn to take care of himself, without trusting to the bridle: he should also be well reconciled to every noise, and all objects which are calculated to create alarm: another person mounted should gallop

by or past him, cracking a whip and making a great noise : he will thus become so perfectly steady that a lady may ride him with the utmost confidence and safety. The canter is the pace best calculated for a female.

*Butchers' Hacks* are remarkable equally for their mean appearance and the long journeys which they perform. Butchers are hard riders, and they contrive to make their rough-looking nags go a great distance in a very short time. At first view this seems surprising, as their hacks seldom manifest any very high pretensions to breeding, and at the same time very often appear battered and blemished; their condition too, none of the best. I must confess I have scarcely ever been able to satisfy myself on this score.—However, it may be justly remarked, that butchers are seldom sparing of the spur (they seldom appear with more than one;) or the ash plant; and although they perform long journeys in a short space of time, their hacks seldom fail to exhibit incontestible proofs of the violence which has been called into action for the purpose of forcing the animal to accomplish the object which the rider had in view. But it is not always that the unfortunate quadruped is able to perform the inhuman task imposed upon him:—nature sinks under it, and the creature expires.—A butcher, now living, while riding between Chester, and what is called the Rock Ferry, on the banks of the Mersey, perceived his horse lame, five or six miles before he reached the last mentioned place, and as he rode along, a rustic called to him, saying that his horse's near fore foot was covered with blood:—the blood was oozing out at the coronet, owing most likely to a wrench, from the foot catching between two stones. The fellow, nevertheless, forced the animal forward: he reached the Rock Ferry, where his horse walked, as it were, out of his hoof—*it came completely away!* The trot is the butcher's general pace; and, it may correctly be observed, that, if the horse has any trot in him, they will bring it out: little doubt can be entertained, that the trot is the least fatiguing to a horse of any of his quick paces, and that which will enable him to accomplish long journeys in the shortest period of time. Butchers' hacks are seldom much better than screws, at least in appearance—they are almost every where to be met with: butchers indeed may be regarded as a sort of semi-horse-dealers; they are often changing their hacks.

It may be observed of butchers, that they slaughter their hacks as well as their cattle; or, in other words, by mere dint of punishment, they compel the horse to perform that of which he is generally supposed incapable.

Finally, it may be remarked, that a horse with thin shoulders, and a flat chest, whose fore feet stand boldly forward and even, his neck rising rather semicircularly from the points of those thin shoulders to his head, may justly be said to have a light forehand, and to be better calculated for the saddle than the collar. As most horses in the hands of farmers, while young, are drawn, which, notwithstanding their make, occasions them to move heavily, if you desire a nimble footed horse, choose one that has never drawn.

**HACK, COVER.** A horse used by sportsmen to ride to the

fixture, or place of the hounds' meeting, when the hunter is mounted, having been previously sent forward by a servant.

HAIR,—with which the frame of the horse is so completely covered, and more familiarly termed *coat*, is, in general, indicative of the good or ill state of the horse; not only in respect to health, but to his condition, for whatever work he may be designed. If the subject is sleek in his coat, with a glossy shining surface, soft and pliable in the skin; not tight upon the ribs, as if firmly adhering to the side; no enlargements upon the lower joints of the legs, nor any profuse and faint perspiration upon moderate work, the blood may be pronounced in a healthy state, and the horse in fair and good condition.

If, on the contrary, the coat is rough, hollow, staring different ways, of a variegated hue, with a tinge of dust or scaly scurf beneath the surface, the perspirative matter has been thrown upon the circulation by a collapsion of the porous system, the blood is become sizzly, and disposed to morbidity, in proportion to the preternatural weight by which it is overloaded, and the obstructions it has to encounter in its passage through the finer vessels, occasioned by the languor of the circulation.

Where a loss of hair has been sustained by some injury, as in broken knees, wounds after being healed, blistering or firing, the growth may be promoted (particularly in slight cases) by reducing three drachms of camphire to fine powder, then letting it be well incorporated with two ounces of spermaceti ointment, upon a marble slab, and a small portion of it well rubbed into the part affected at least once, but it will be better if persevered in twice, a day. Neats' foot oil, sheep's foot oil, or indeed any animal oil is still better, and more simple.

HALLOO.—A term or shout frequently used in the chase. In coursing, where a hare is started, the dogs are excited to pursue by the vociferation of *Halloo!* *Halloo!*—In hunting, its meaning will require a more verbose explanation; halloos may be called the language of the chase: they are used to encourage the hounds, as well as for the purpose of reprehension; there is also the view halloo: the meaning of which will be very intelligibly explained by a few words from Beckford.—“I have a friend (says he) who hunts his own hounds, who has the strangest voice, and the oddest halloo, I ever heard. He has, however, this advantage: no dog can possibly mistake his halloo for another. Singularity constitutes an essential part of a

huntsman's halloo:—it is for that reason alone, I prefer the horn, to which, I observe, hounds fly more readily than to the huntsman's voice. Good voices certainly are pleasing; yet it might be as well, perhaps, if those who have them, were less fond of showing them. When a fox is hallooed, those who understand this business, and get forward, may halloo him again; yet, let them be told, if the hounds go the contrary way, or do not seem to come on, upon the line of him, to halloo no more. With regard to its being the hunted fox, the fox which every man halloos is the hunted fox in his own opinion, though he seldom has a better reason for it than because *he* saw him. Such halloos as serve to keep the hounds together, and to get on the tail hounds, are always of use; it is the halloos of encouragement to the leading hounds, when injudiciously given, that spoil your sport. I am sorry to say, view halloos frequently do more harm than good. They are pleasing to sportsmen, but prejudicial to hounds. If a strong cover be full of foxes and they are often hallooed, hounds seldom take much pains in hunting them: hence arises that coldness and indifference, which may be sometimes observed in fox hounds when pursuing their game.” Hounds should never be taken off to a halloo, if they are running with a good scent; but if otherwise, and the halloo can be depended on, it may be advisable to lift or take the hounds to the spot, particularly if the fox is a great way before them, or persists in running his foil; as such foxes are difficult to kill, unless you get nearer to them by some means or other. Hounds may be hallooed too much. If they are often used to a halloo, they will expect it, and may trust perhaps to their ears and eyes more than to their noses. While hounds can get on with the scent, it cannot be right to take them off from it; but when they are stopped for want of it, it cannot then be wrong to give them every advantage in your power. A huntsman should nevertheless be cautious of going to a distant halloo. The halloo itself must, in a great measure, direct him; and though it affords no certain rule, yet you may frequently guess by it whether any reliance can be placed on it. However, if it is resolved to go to a halloo, the sooner the hounds reach it the better. Huntsmen who are slow at getting to a halloo are void of com-

mon sense. They frequently commit another fault by being in too great a hurry when they are there. "It is hardly credible (says Beckford) how much our eagerness is apt, at such a time, to mislead our judgment: for instance, when we get to the halloo, the first questions are natural enough:—Did you see the fox?—which way did he go?—The man points with his finger perhaps, and then away you all ride as fast as you can; and in such a hurry, that not one will stay to hear the answer which you all were so desirous of knowing: the general consequence of which is, you mistake the place, and are obliged to return to the man for better information."—In hunting the stag and the hare, halloos are used in a somewhat similar manner; though they should not be nearly so often resorted to with harriers as with fox hounds.—The English halloo is unquestionably derived from a similar term used by French sportsmen in wolf hunting, "*au Loup!*" (to wolf!) the sound of which, as every one acquainted with the French language will instantly recognise, is precisely similar.

It will be necessary here to remark, that, though the language of the chase, or rather the language used to hounds, is comprised under the general denomination of *Halloo*, yet the word itself, that is, halloo, is made use of in scarcely any other instance than when a hare starts before greyhounds:—on this occasion, a cry of *Hal-loo! Halloo!* is raised by the sportsmen, in order to induce the greyhounds to look out for their game and pursue it. As to the language of huntsmen to their hounds, though, as before observed, it is comprehended under the general term *Halloo*, yet it is branched out into a variety of sounds, all of which are of course understood by the hounds. It seldom happens indeed that two huntsmen have precisely the same tone, which, however, is of no consequence so long as the meaning is understood or correctly interpreted by the hounds: indeed, any peculiarity in the voice of a huntsman may be said to be advantageous to the hounds, as, under such circumstances, they can never mistake his voice for that of another. It is frequently difficult, in the general halloos of huntsmen, to discover any definite word, but the corruption of a well-defined expression may be mostly traced: *Yoic* is the word (or halloo) from which many of the corruptions or deviations may be traced. *Here, boy!* is also tortured into a variety of forms (if the expression may be allowed);

and indeed so many of these ill-defined deviations present themselves, that it is not possible to image them to the mind by any form of words on paper: at the same time, it may be justly remarked, that some of the terms (halloos) which seem to admit of no deviation, the most prominent of which, are *tallyho* and *whoo-whoop*, the former appears to have been derived from the French *au tailli*, to cover; though it is used in a sense somewhat different by English sportsmen.—*Tallyho!* is the term for a fox breaking cover or going away, and indeed every time he is viewed: *whoo-whoop* is used at the death, and constitutes of course what we call the death halloo.—*Whoo-whoop* is most likely derived from the same language as *tallyho*; and it is highly probable that most, if not all, our terms of the chase sprung from the same source, and were originally introduced by the Normans.

**HALTER** is that well-known convenience by which a horse is fastened to the manger when confined in the stable.

**HALTER-CAST.** This is an accident to which horses are constantly liable, and it very frequently happens; but, in general, from the inadvertency of leaving the rein of the halter of too great a length on either one side or the other: for when the horse is lying down, and has occasion (from itching, or some other cause) to rub his neck or head with the hind foot, it is no uncommon thing to have it get entangled in the halter-rein; which encircling the cavity of the heel, renders it impossible for the animal to extricate himself, unless the halter breaks in his favour; and during these struggles, the heel is sometimes so terribly excoriated, as to become not only a wound of much trouble, anxiety, and loss of labour, but often leaves a very vexatious blemish, never to be removed.

**HALTING** may be considered a limping, or slight impediment to free and easy action, implying some kind of perceptible defect or disquietude, not amounting to absolute lameness.

**HAM, HOUGH, OR HOCK**, is the joint in the centre of the hind leg; and although so wonderfully united for strength and action, is nevertheless the seat of serious injuries, as spavins, curbs, &c.

**HAMBLETONIAN** was bred by Mr. Hutchinson, of Skimpton, near York, and foaled in 1792; was got by King Fergus; dam by Highflyer; grand-dam by Matchem.—1795, May 5, when three years old, he won a stakes of fifteen gui-

neas each, over Hambleton, (five subscribers) beating Sober Robin, Tarquin, and another. At York, May 20, he won a sweepstakes of twenty guineas each, four subscribers. He was then purchased, with all his engagements, by Sir C. Turner, Bart. in whose possession he won, on the 27th of August, at York, a sweepstakes of 100 guineas each, (six subscribers) beating Benjamin, Minus, and Maximus. Two days after, he won a sweepstakes of fifty guineas each (four subscribers). At Doncaster, the 22nd of September, he won the St. Leger stakes of 25 guineas each, twelve subscribers. The next day he won the gold cup of 100 guineas value, four miles, beating Governor, Capsicum, and Bradamant. 1796, at the York August meeting, he won a subscription purse of 227*l.* 10*s.* beating Spread Eagle, Sober Robin, and another. The next day he won the ladies' plate, beating Lord Darlington's St. George. At this period of uninterrupted success, he was purchased by Sir Henry Tempest Vane, Bart. and at Doncaster, September 28, won the gold cup of 100 guineas value, beating Sir Robin, Ambrosio, and three others. In the Newmarket Houghton meeting, November 2, he beat Mr. Tatton's Patriot (who was got by Rockingham) over the Beacon course, for 1000 guineas. 1797, Monday, in the Newmarket Craven meeting, he won the Craven stakes of ten guineas each, beating Sober Robin, Bennington, Paynator, Hermione, Parisot, Cymbeline, and five others. The same day he received 250 guineas forfeit from Spread Eagle. On Thursday, in the same week, he beat Lord Clermont's Aimator, Beacon course, 300 guineas. At York, August 23, he won one third of the great subscription of 25 guineas each, (twenty-five subscribers) to which was added a 50*l.* plate given by the city. The next day he won another third of the same subscription, with an additional 50*l.* plate by the city, beating Beningbrough, Trimbush and Brilliant. At Doncaster, the 27th of September, he won the stakes of ten guineas each, (ten subscribers) with twenty guineas added by the corporation; and on the 29th, received 100 guineas forfeit from Mr. Sitwell's Moorcock. In 1798, he was slightly lame, and never started. 1799, Monday, in the Craven meeting at Newmarket, he beat Mr. Cookson's famous horse, Diamond, over the Beacon, for 3000 guineas, with the odds of five to four in his favour, on ac-

count of his superiority in size and strength; it being jocularly observed by the rider of Diamond at starting, that it seemed "a little like a race between a mare and her colt." This match was the greatest in popularity ever known from one extremity of the kingdom to the other, and was decided before one of the fullest meetings ever seen at Newmarket. It was won by no more than three parts of a length, to effect which, the winner had felt the utmost force of the spur; and, it was generally believed, if they had had then one hundred yards farther to have ran, Diamond would have been the winner; in proof of the justice of which opinion, Mr. Cookson challenged a repetition of the match, which was declined.

At Doncaster the same year, he won the renewed stakes of ten guineas each, (fourteen subscribers) with twenty guineas added by the corporation, beating eight of the best horses in the north of England. In 1800, he won the great subscription at York, with 50*l.* given by the city, which was the last time he started. He once ran out of the course, soon after starting, when running three miles over York, 1797, for a sweepstakes of 100 guineas each, against Deserter and Spread Eagle; and paid one forfeit to Sterling (from being amiss in 1792) at Newmarket; but never was beat.

**HAND** is the term for a mode of measurement by which the height of a horse is ascertained. A hand (so called originally from its breadth) is four inches; three hands is consequently one foot; and a horse of fifteen hands is exactly five feet high.

*Bridle-hand.* The left hand is so termed, in contra-distinction to the right, which is called the whip-hand.

To say a horse is light in hand, implies his being playful, lively, champing his bit, firm upon his haunches, and not dwelling upon the ground with his fore feet. A horse is heavy in hand, when, bearing his weight upon the bit, and lifting his fore legs with reluctance, he goes boring on, with no other sensation to the rider, than an eternal fear of his pitching upon his head. A vicious horse, breaking away with his rider, seems a dreadful sight to a spectator, but can never be attended with misfortune, if the rider is a good horseman, and has him "well in hand," which is, in fact, the power of "gathering him together," or stopping his career at pleasure.

*Hand-gallop* is that easy kind of pacing

adapted to the aged and infirm, who wish to obtain every possible degree of motion, most consonant to bodily ease ; it is the degree of equestrian action synonymous with, and more universally known by, the denomination of *canter* ; which is, in fact, the slowest, or most contracted, gallop, and can only be enjoyed by those who possess horses of good temper, and well broke for the purpose.

A colt said to be "taken in hand," implies his being brought from the field to be handled, quieted, led about, and stabled, previous to his being broke in for the saddle or harness.

**HANDICAP.** A handicap match, is A, B, and C, to put an equal sum each into a hat ; C, who is the handicapper, makes a match for A and B, who, when they have perused it, put their hands into their pockets and draw them out closed ; then they open them together, and if both have money in their hands, the match is confirmed ; if neither have money, it is no match. In both cases, the handicapper draws all the money out of the hat ; but if one has money in his hand, and the other none, then it is no match ; and he that has money in his hand is entitled to the deposit in the hat.

**HARE.** The hare is one of the most timid animals in nature : fearful of every danger, and attentive to every alarm, it is continually upon the watch ; and being provided with very long ears, which are movable at pleasure, and easily directed to any quarter, it is warned of the distant approach of its enemies. As the hare is destitute of the means of defence, nature has aided it with the powers of evasion in a surprising degree : every part and member of this animal seems peculiarly formed for celerity, and it is consequently one of the swiftest quadrupeds in the world. Its hind legs are much longer than the fore ones, and are furnished with strong muscles, which give it a singular advantage in running up a hill ; and of this it appears very sensible, as it is generally observed to fly towards rising ground when first started.

The colour of this animal is another great means of its preservation, as it often so much resembles the ground on which it sits, as not to be easily distinguished. In cold countries near the pole, where the ground is covered with snow the greater part of the year, the hare becomes white, or at least assumes the colour of the country it inhabits ; and it is thus rendered less conspicuous in those frigid regions.

Thus formed for escape, it might be supposed, the hare would enjoy a state of tolerable security ; but, although harmless and inoffensive in itself, it has no friend. Dogs of all kinds, as well as foxes, pursue it, seemingly by instinct ; wild cats, weasels, &c. catch and destroy it ; birds of prey are still more dangerous enemies ; while man, more powerful than all, makes use of every artifice to obtain

*Free Handicap* is an expression which frequently appears in race lists, the meaning of which is, that a number of horses being named, a weight is placed against the name of each, by the clerk of the races, or some disinterested person, who is well acquainted with the performances of the horses. These weights are supposed to be such as will bring all the horses as nearly on a par as possible ; and the list containing them being handed to the owner of each horse, they accept or decline according as they imagine the chances are for or against them.

**HANDING A COCK.** See **COCKING**.

**HANDLING.** A term applied by cockers to the judicious handling of a cock, when brought up from his walk, to ascertain whether he is in proper condition to be placed in the pens. This is done by a particular mode of taking the girth of the body by grasp, to discover the shape and substance, the bone, the probable strength, as well as the firmness or flaccidity of the flesh.

**HARBOUR** is a sporting term applicable to deer, and used in stag hunting. A stag is said *to harbour* when he goes to rest ; and to *unharbour* a deer is to dislodge him.

## H A R E

a creature which constitutes one of the numerous delicacies of his table.

According to naturalists, the hare lives six or seven years, and attains its growth in one ; though there is much reason to believe, that, if undisturbed it would live much longer than the period just stated. It engenders frequently before it is a year old. The buck seeks the doe principally from the month of January to the month of April. The female goes with young thirty or thirty-one days, and brings forth generally two young ones (though they have been known to produce three or four) and deposits them in a tuft of grass or heath, or in a little bush, without any apparent preparation.

The ridiculous assertions which some writers on natural history have made, viz. of hares being generally hermaphrodites, or of changing their sex every month, as well as of possessing the power of superfetation, are too glaringly absurd to need a detailed refutation in this place. The circumstance which seems to have given rise to the first of these notions is the formation of the genital parts of the male hare, whose testicles do not obviously appear when he is young. Another reason is, that on the side of the penis, which is scarcely to be distinguished, there is an oblong and deep slit, the orifice of which, in some measure, resembles the vulva of the female. The male and female are known to the sportsman by the following distinctions : the head of the male is more short and round, the whiskers long, the shoulders more ruddy, and the ears shorter and broader than those of the female ; whose head is long and narrow, the ears long, and sharp at the tip, the fur on the back of a grey colour, inclining to black, and in point of size she is frequently found smaller than the male. There is also considerable difference in the feet. In the male, the feet are small and pointed, and the nails short ; whereas, in the female, they are much longer and more spread ; the nails also are much longer.

Two species of hare may be distinguished : those of the wood, and those of the plain. The hares of the wood are in general much larger than those of the open ground ; the fur is not of so dark a colour, and they are better covered with it ; they are also supposed to be swifter in the chase, and their flesh to possess a finer flavour. These distinctions, however, are rather fanciful than real ; but the following is true enough :—Among the hares of the plain, those may be distinguished which inhabit marshes ; they are scarcely so large, perhaps not quite so swift, are less covered with fur, are darker coloured, and their flesh is neither so fine flavoured nor so delicate.

A young hare that has attained the full growth may be known from an old one by feeling the knee joints of the fore legs with the thumb nail. When the heads of the two bones which form the joint are so close, that little or no space is to be perceived between them, the hare is old. If, on the contrary, there is a perceptible separation, the hare is young ; and is more or less so, in proportion to the separation of the bones. It may also be known whether a hare is old or young, but without pretending to ascertain the precise age, by compressing the under jaw bones : if they break at the point immediately

## H A R E

under the fore teeth, upon a slight degree of pressure, the hare is certainly a young one; but if considerable force is required, the contrary may be inferred.

The hare is very prolific, and it is supposed the female will take the buck the latter end of the same season the early part of which gave it birth. In fact, were it not for its surprising fecundity, the species, in England, at least, would soon become extinct. To say nothing of its other numerous enemies, this animal appears to be the peculiar object of the poacher. There are various methods of taking them, and so little skill is required, that any bungler is able to execute his purpose. The wire snare is most commonly employed by the poacher, though hares may be covered on their seats in the day time with a net, much easier than a covey of partridges.

Those who are desirous of having hares very numerous in their parks or warrens, should destroy some of their buck hares before the rutting season; as, if the latter are left in great numbers, they will prevent the does breeding properly by their incessant teasing.

The hare, of which we have been speaking, is found in all the warm and temperate climates; but there remains the *white* or *Alpine hare* yet to describe. The alpine hare is smaller than the common hare, for the reason which we gave under the head of the ptarmigan or white grouse. The following is a particular description:—The alpine hare is about nine inches in length. It has a long head and whiskers; and above each eye there are two very long hairs. The ears are short and rounded. The fur is dusky at the roots, of a bright bay at the ends, slightly tipped with white, and intermixed with long dusky hairs; at first sight, the animal appears of a bright unmixed colour.

Such is the description of the alpine hare by one who has written on the subject; and who had perhaps an opportunity of examining a solitary individual. The fact is, that the alpine hare, like the ptarmigan, alters its appearance according to the season, and in winter, when snow covers those regions where it is found, it becomes so white as scarcely to be distinguished from the general colour of its abode. Like the ptarmigan, the alpine hare is found on the tops of the higher mountains of the Highlands of Scotland, and changes its colour according to the season of the year.

“ Their most southern residence (say naturalists) is on the Altaic chain of mountains near the lake Baikal, in Siberia; and they extend from thence as far northward as to Kamtschatka. They are always found in the middle regions of the snowy mountains, where these are clad with woods, and where herbs and moisture abound. They sometimes burrow between the rocks, but more frequently lodge in the crevices. They are generally found in pairs; but, in bad weather, they collect together, lie on the rocks, and whistle so much like the chirp of a sparrow as to easily deceive the hearer. On the report of a gun, they run off into their holes; whence, however, if nothing more is heard, they soon return.

“ By the usual wonderful instinct of similar animals, they make a provision against the rigorous season. A company of them, towards

autumn, collect together vast heaps of favourite herbs and grasses, nicely dried; which they place either beneath the overhanging rocks, or between the chasms, or around the trunk of some tree. The way to these heaps is marked by a worn path; and in many places the plants appear scattered, as if to be dried in the sun and harvested properly. The heaps are formed like round or conoid ricks; and are of various sizes, according to the number of the society employed in forming them. They are sometimes about a man's height, and usually three or four feet in diameter.

“Thus they wisely provide their winter's stock; without which they must, in the cold season, infallibly perish; being prevented by the depth of snow, from quitting their chosen retreat in quest of food. They select the most excellent vegetables, and crop them when in their fullest vigour. These they make into the best and greenest hay, by the very judicious manner in which they dry them. The ricks they thus form are the origin of fertility among the rocks; for the relics, mixed with the dung of the animals, rot in the barren chasms, and create a soil productive of vegetation.”

But to return to the hare, which is so numerously found amongst us, the author of an Essay on Hare Hunting says, that he has accurately noticed the refined senses of *smelling* and *hearing* which she possesses, particularly the latter. All the hare's dependance, says this writer, is on this talent alone; still, however, there is one inconvenience attending it, that whilst this sense of hearing is so exquisitely alive to any noise proceeding from behind, yet a hare under pursuit has but an imperfect aid from her ears straight before or sideways. It is this ability of hearing so accurately from behind that enables her to avoid the throw of the greyhound; and, when hunted, to continue her course till quite clear from the clamour of the hounds; although, at the same time, deaf to the noise of foes before, and having all her faculties employed on that single point of hearing and flying from the peril that pursues. On advancing such a seeming improbability, most of the sportsmen in England will smile, but let them ask any anatomist, who has inspected the structure of this creature's ears, and he will (says the writer) justify my assertion.

As the only mode of preservation the hare has is flying from danger, it is easy to perceive the reason of her being endowed with this exquisite sense of *sound*, by which she may receive timely information of the distant or near approach of her enemy; destitute of such quickness of hearing from behind, a hare might run herself blind, or until she died, after she was out of danger, from the want of being conscious that she was so. No sportsman can correctly assert, that a fresh hare started or coursed ever stops or turns her head to look back; how is she sensible then that she is clear from the enemy that pursued her? Her *ears* are her constant and unerring instructors.

It has been confidently mentioned, he continues, that a hare, when hunted, hearkens with one ear to the cry of the hounds, and stretches out the other as a sail to promote her course. This notion is ridiculous. Whenever she pricks her ears on end, or draws one apart from,

## H A R E

or forwarder than, the other, it is to listen more distinctly on that side the forwardest ear inclines to; had nature designed any singular aid to her feet from stretching forth the ears, she would have supplied her with *two pair*, one to lie flat upon the shoulders for listening, whilst she sailed by the other; and never would she have had more occasion for both, than when severely coursed, at which time the ears she has may be observed to lie close to the neck; and although she is compelled, when thus pressed, to try every shift to escape, this quality of sailing by the ears is never seen; both ears are very strictly applied to catch the smallest sound of the greyhound *behind*, by which she accordingly retards or increases her speed.

That Providence has furnished every creature with endowments proper for preservation, the attainment of food, and for defence, is obviously certain. Enquire of a country labourer, why an owl, at the dusk of the evening, sits on the barn door, or perches upon a gate post, rail, or beam?—his immediate answer will be, that it is watching for a mouse. A man, without being a very eminent naturalist, knows the owl is *hearkening*, rather than looking, for a mouse; its *ears* give it notice of the motions of its prey, long before its *eyes* distinguish it; but, in this nicety of hearing, it is to be remembered, that owls are circumscribed; their ears are chiefly excellent in hearing what happens *beneath*; their hearing is very imperfect when the sound proceeds from *before* or *sideways*, nor have they the least advantage in hearing any thing *above* them; admitting that they could hear acutely from *above*, to what purpose would it tend? They have not the least expectation of mice running over their heads, but directly the contrary; and for that reason, nature has befriended them in the confining their sense of hearing in perfection, to what passes *beneath* them.

The fox that roves about, and has various means of acquiring subsistence, depends greatly upon the faculty of hearing from *above*, which he possesses superior to most creatures, and equal to any. What principle, is it imagined, directs him in his prowlings, to lurk underneath, or climb the pear or plumb tree where the poultry roost?—not so much his eyes as his ears; a feather is scarcely moved but he hears it. On the other hand, the polecat's talent consists in hearing directly *forward*; he is deaf as an adder, both to his prey and to his danger, behind. This is not offered as conjecture, but as matter of fact, the animals' ears being constructed for such peculiar modes of hearing, especially the passage directing to the *os petrosum*, which, in an owl's ear, is produced further out above than below, for the better reception of sound *ascending*; in a fox, it is exactly the reverse, and calculated to intercept the least noise from *above*; in a polecat, far before, to take the *forward* sound; but the ear of the hare is supplied with a tube directed extremely *backward*. It is owing to these backward tubes that she perceives the smallest sound that comes from that quarter, and acts upon it so instantaneously for her preservation.

The deficiency of the hare's sight straight forward is generally known; and, when close pursued, the fear of the dogs takes away her

presence of mind, and she will frequently run against objects; from whence has arisen the vulgar notion of the hare running herself *blind*. Some insist that hares are of the tribe of *nocturnal* animals, that have imperfect sight in the day, and that their eyes are of a similar texture to those of cats or owls. I am no oculist (says the author) but if common reason may be attended to, it is natural to suppose that *night* or *day* is indifferent to the hare; and that she only prefers the former to relieve in, from its being the most favourable and least dangerous time. The disadvantage of wanting *quick* sight before may be accounted for from the situation of the eyes, which are fixed in the head at a distance from each other, like those of the horse; the eyes are formed to turn in their sockets every way; and it is evident that by so much as the eyes are turned out of the centre of sight to look *upward*, they can the less see *downward*; and by so much as they are strained towards the nose to see *forward*, they can be the less directed for sight *backward*, supposing the head to be steady and fixed, which is the case when a hare runs fast; at other times, she turns and manages her head as she pleases. In an even posture of body, the eyes appear situated to see quickest and best full on each side; whence it arises that a coursed or hunted hare does not see clear directly *forward*; and the reason is, that being chiefly apprehensive of danger from behind, she employs all her senses to escape that danger, and the more effectually to accomplish it, endeavours to see it, and strains her eyes as *backward* as possible, according to the degree of terror she is in; so that she becomes (for want of a due proportion of her vision employed forward) frequently a victim to the enemy before her. Any person may experience the truth of the foregoing remark, that will cast his eyes upward or downward, or from side to side; he will soon find, when he points them in one direction, how imperfect his sight is in the other.

Whether a hare's eyes receive any inconveniency from being so large and convex, or that they suffer damage by being exposed night and day to dust and prickles, from the lids not covering them completely, cannot be determined; but it is certain that hares do not see so perfectly before as *sideways* or *aslant*; and indeed nature has in some measure compensated for this defect, and likewise that of not hearing forward, by an incomparable sense of *smelling*; not the sort of smelling peculiar to hounds, but that species which sportsmen term *winding*, as when a dog holds up his nose on smelling carrion. The hare has this faculty in such perfection, that, with the wind in her favour, she will never come within a certain distance of a person, however closely concealed.

Some believe (continues the author) that hares propagate but *once* a year, but they breed from February to the end of harvest. The paps of the doe come forwarder under her belly, than those of almost any other quadruped; she does not long suckle her young; if she did, and had many, the udder would be drawn too big, and lie inconveniently whilst the hare was running; she brings forth differently from the rabbit, her offspring being completely formed and quick-sighted the instant they are dropped.

## H A R E

It is a well experienced truth that some places are remarkable for being seldom without hares; and others (although as likely in all appearance) rarely with any. Whether it is any particular excellence in the *feed*, in the situation for *forming* advantageously, for warmth, hearing, or seeing, that induces them to prefer certain spots to others, or that on the death of a buck or doe another succeeds, and they possess their usual circle, cannot be ascertained; but the fact is perfectly established.

The following circumstance will prove that the hare, when alarmed, sees but very imperfectly forward:—In Sandpit Wood, in the parish of Terling, in Essex, a pack of fox-hounds, very early in the season of 1782, had just unkennelled, and the hares, of which, as well as of the foxes, there were plenty in the cover, were many of them disturbed. In one of the paths, a hare met and ran against a terrier that was hastening to the cry, with such velocity, that both animals were apparently killed: the dog, with some difficulty, was restored, but the hare's skull was completely fractured.

In a wood belonging to Mr. Corbet, of Strawberry Park, in Shropshire, a hare very nearly of a pure white, was killed in November, 1797, which weighed upwards of nine pounds; and a singular account is given for this change of colour, which is imagined to have proceeded from the animal being overheated, to which its *terror* probably added: a much more reasonable way, however, of accounting for this change of colour, would be to ascribe it to the effect of age:—the writer has, at various periods, seen several very light coloured or white hares, which were all remarkable for age. It is certain that when a hare becomes what may be called old (four years of age, for instance) she assumes a lighter colour, she becomes grey, (strictly according to the general system of nature) and this lighter colour continues to whiten as long as she lives. All old hares are difficult to kill, and the striking fact of the one above mentioned so often beating the dogs, serves to confirm the idea that her colour proceeded from age rather than from any adventitious circumstance. She was well known to have been often coursed by greyhounds; and some time before her death, she was run by three greyhounds: one of the dogs caught and died with the hare in his mouth, and she made her escape; the other two greyhounds were to all appearance dead; but by bleeding and proper treatment they recovered. As a proof of its being the same hare, half of the scut remained in the dog's mouth that died, and when the hare was killed she wanted that part. She was at last chopped by a pointer upon her seat; and her skin was preserved as a curiosity.

An old hare, which has been repeatedly run, does not easily surrender her life. One of this kind, grown nearly white with age, was well known in the parish of Lathom, in Lancashire, about the year 1807. The writer saw her coursed several times, and she uniformly escaped. The last time he saw her run was by two excellent dogs belonging to Mr. T. Brandreth, of Ormskirk, one of them in particular, a light coloured dog, called Topper, was supposed to be the fleetest greyhound in that part of the kingdom. The course exhibited

## II A R E

a desperate struggle between the hare and the dogs, during which two other dogs that were upon the ground accidentally broke loose, and joined in the pursuit. The hare, however, beat them all.

In February, 1804, a hare, completely *white*, was started by the Lisburn club hounds, and after a chase of nearly an hour was taken alive.

In further confirmation of the difficulty of killing an old hare, the writer will take leave to mention, that a hare had for several years frequented a particular corner of the township of Maghull, eight miles on the north road from Liverpool. She was repeatedly seen in the garden belonging to Henry Meadows, the village blacksmith, as well as several other gardens in the immediate neighbourhood. She had many times beaten the greyhounds; and in the winter of 1824-1825, she was repeatedly run by the harriers of R. Seed, Esq. as well as coursed by greyhounds. The writer, who generally followed the harriers just mentioned, was, upon one occasion, accidentally afforded an opportunity of observing this hare's manœuvres, when she was before the harriers, and was much surprised at the extraordinary sagacity manifested by her. She was one day pressed so hard by these staunch little harriers, that, after a long and a hard run, she was under the necessity of crossing the canal, which saved her life. This hare was always to be found at home; and whenever the harriers were at a loss for diversion, they knew where to procure a run.

One of the "mean, murderous, coursing crew," who lived in a neighbouring township, and was proud of his greyhounds, visited Maghull, found the hare, and was beaten by her. A few days afterwards, he run her with a leash of greyhounds, and two couple of beagles; and yet she escaped. Bent on her destruction, the courser, a few days afterwards, again came to Maghull, accompanied by two couple of greyhounds, and three couple of beagles. The hare was well known in the neighbourhood, and, from her gallant conduct so many times, had become a great favourite; when therefore such a murderous phalanx appeared, accompanied by a host of myrmidonian bipeds, it created a sort of ferment in the village. The man's former conduct had excited the most superlative disgust of the sportsmen in the neighbourhood, and had filled the village with murmurs of disapprobation. The women upbraided the courser as he passed along; but he proceeded, regardless of the taunts and wordy war. Six beagles and four greyhounds against one poor hare!!!

The hare, as usual, was easily found, and beat the four greyhounds handsomely; but the business was not to end here. The poor hare was again put up by the beagles, and again she beat the tremendous odds which had been arrayed against her. Again the beagles were put upon her foot, again she was viewed, and, as a last resource, made her way into the garden of Henry Meadows, the village blacksmith. Here she was surrounded, not only by the dogs, but the myrmidonian band before mentioned; the latter repeatedly struck at the hare with their staves, and the poor animal thus unfairly lost its life—was thus miserably murdered! Henry Meadows, who had watched the operations of these *highly accomplished sportsmen*,

## H A R E

through one of the windows of his shop, no sooner heard the foul death cry of his old acquaintance, than, snatching the fiery bolt from his forge, he charged the semi-assassins with the utmost fury; who thereupon took to flight, leaving the village amidst the general execrations of the rustics.

In Siberia, were once seen by Mr. Muller, two hares of a jet black and wonderfully fine gloss; and in the winter of 1768, a third was taken near Casan: these exceeded the common hare very much in bulk.

A black hare was seen by Captain Colquitt, R. N. in the winter of 1822, in the neighbourhood of Seacombe, in Cheshire.

In February, 1789, the hounds of Mr. Barnard, of Linsell Hall, found a hare near Falsted, in Essex, which was taken alive, out of a drain in a farm yard, after running upwards of twenty miles in a little less than two hours.

In October, 1792, a hare after a chase of sixteen miles by the Seaford hounds, took the sea near Cuckmere, in Sussex, and swam a quarter of a mile from shore, before she was overtaken by the dogs.

Mr. Pleydell's harriers, hunting in the Isle of Purbeck, in 1795, found a hare, which, after some running, took towards the sea, and on the edge of one of the highest cliffs the hounds came to a check. A cast was made both to the right and left without effect; and some foot people having seen the hare exactly at that spot, without being able to view her afterwards, both hounds and sportsmen were at a loss, as it appeared impossible for her to have got down the rocks alive, and if she had been killed at the bottom she must have been seen. While each man was giving his opinion, the hare was perceived in the sea, dead, and continually rolling over with the waves. A person who knew where he could descend the precipice, went and brought her up. Upon examining her, both thighs were found to be broken. The cliff was at least seventy feet high, and as the sea was at some distance from its bottom, the animal must have leaped from the summit as far as she was able, or could not otherwise have reached the water. The most remarkable part of the circumstance is, that the hare should have taken this extraordinary leap, when the hounds were not within a quarter of a mile of her, and consequently there was no immediate escape from the hounds to incite this uncommon act of self destruction.

Lord Ongley's harriers, in March, 1798, in the course of a very hard chase of three hours, ran a hare through part of eight parishes, and three counties.

Mr. Feuston's harriers found a hare at Metfield, which ran through seven parishes in Suffolk, then crossed a river, and after a chase of four hours and a half, was killed at Mendham, in Norfolk.

It is not unfrequent in an inclosed country for the hare to betake herself to the wood or brick drain, when over-rated by the greyhound; and there was once a story published of some *sportsmen*, who blocked up this sort of retreat the *fourth* course, although poor pussy had thrice beaten their dogs. Yet this is not so bad as the conduct of the courser previously mentioned.

## II A R E

Hares are sometimes killed by hawking, and the Iceland hawk is used for this quarry; the hare, however, feels the hawk's superiority so much, that she would not stir, were she not impelled by a dog to keep upon her legs; the poor animal is thus placed betwixt two enemies, and some time generally elapses before the hawk gives the *coup de grace*.

The hare's most favourite food is pinks, parsley, carrots, and birch; in hard weather they will eat haws; and in young plantations they are highly injurious by eating the bark from the trees, which they will do from almost every sort, the alder and lime amongst the exceptions.

Hares will do great mischief among flowering shrubs, and are fond of Spanish broom, scorpion senna, and evergreen cytissus. The following mixture, which answers very well in the preservation of trees, is not so easily applied to shrubs; but by circling their branches with new tar twine, put several times round the shrub, it has had the desired effect. The tar twine, exposed to the air and rain, will lose its smell and must occasionally be renewed:—Take any quantity of tar, and six or seven times as much grease, mixing them well together: with this composition, brush the stems of young trees as high as rabbits and hares can reach, and it will effectually prevent their being *barked*.

Hares and rabbits have an aversion to tar, which, though fluid, when exposed to the sun and air, contracts great dryness and a very binding quality, and if applied to trees in a pure state will perhaps occasion them to become bark bound: the addition of the grease, before mentioned, prevents this effect.

In the year 1798, a Suffolk gentleman was obliged to destroy his hares near some new plantations; and the amount of what was known to have fallen victims, was *five hundred and forty-one brace*!

Lord Craven, in December, 1804, in the course of a few days, killed in Ashdown Park, *eight hundred brace*!

We have already remarked, that the hare generally brings forth two at time, sometimes three; but, in the spring of 1799, in the orchard of W. Cole, of Helions Bumpsted, in Essex, seven young hares were found in one form; and what was very remarkable, if true, (which we very much doubt) each leveret was marked with a star of white in its forehead.

According to Buffon, the hare is the only animal which has hair in the inside of its mouth. The breast of the hare is narrow, and at the same time, the *chest* is most capacious. During the time of its being hunted, the lungs are in a continual state of violent expansion, and by the frequent inspiration and expiration become in the end so vastly distended, as to require a much larger space than is assigned for the purpose; the chest therefore is fashioned to receive more breath, or give the lungs more room to perform their office, than in any other creature.

A brace of hares (the doe pregnant when shut up) were inclosed in a large walled garden, and proper plants supplied for their sustenance. At the expiration of twelve months the garden was examined,

## H A R E

and the produce was *fifty-seven* hares, in all ! So at least it is recorded ; but at there is neither name nor date attached to it, we cannot help entertaining some suspicion as to its correctness. Hares are unquestionably very prolific ; and, when thus placed at their ease in the midst of plenty, would be more so than in a state of unlimited freedom, exposed to all the attacks of their numerous enemies, yet, fifty-five young, in one year, partakes somewhat of the marvellous.

Hares, it is said, are subject to *fleas* ; and in summer very much annoyed with *ticks*, which, at that season, swarm in the woods. The writer never recollects observing either of these insects upon the hare ; but sportsmen seldom take the pains, we apprehend, to examine. Linnaeus tells us that cloth made of hares' fur will attract the former insects, and preserve the wearer from their troublesome attacks : Linnaeus is an *awful* authority ; yet few thinking people will give implicit credit to what has been just stated.

There are instances recorded of persons who felt as violent an antipathy to the hare as others have manifested towards a cat. The old Duke d'Eperon, who owed his fortune to his courage, used to faint at the sight of a leveret ; and General Monckton, soon after his return from Quebec, where he had shewn so much heroism as a soldier, and so much affection as a friend, as he was one evening knocking at his own door, fainted away at seeing a cat upon the walls of the area.

Our ancestors deemed it impious to taste the flesh of the hare ; their descendants, on the contrary, brave pains and penalties to obtain it for their tables. The Romans reckoned a young hare a great delicacy, and the *wing* the best part, which our forefathers threw to the dogs.

Pliny, with some degree of doubt, observes, that the flesh of the hare causes *sleep*, and that those eating it look *fair, lovely, and gracious* for a week afterwards. Pliny was an author of great merit, and might be a very honest man, but he was certainly a very credulous writer.

However, let the properties of this animal be what they may, in regard to what has just been stated, the hare was in ancient days preserved as an omen ; and Boadicea, Queen of the Britons, let loose a concealed hare from her bosom immediately before her conflict with the Romans, which, by taking (what by her soldiers was thought) a *fortunate* course, animated them to such a degree that they fought with the most undaunted resolution, and threw the disciplined legions of Rome into confusion.

When Arnold besieged Rome, a hare ran towards the walls and the Germans pursued ; a panic having seized the Romans they deserted the gate, and the Germans became master of the city.

Hares are said to foresee the changes of the weather, and to seat themselves accordingly. Hare finders are in some degree, directed by the wind in looking for hares, which, however, seldom sit in the middle of a field, but at no great distance from the hedge which surrounds it. Shepherds on the Downs assert, that hares have a variety of seats, which, as the weather directs, they change from time to time, and return to again ; and that the more rain that falls, the

## II A R E

nearer to the tops of the hills will the hares seat themselves. When sitting, the hare covers her hind legs with her belly, her fore legs are extended forward, and her chin appears to rest upon them. The author of the Rural Sports, the Rev. W. B. Daniel, observes, that when a hare is seen sitting, its sex may be known :—“ if a *buck*, the ears will be close together ; those of the doe will be distended on each side of the neck and shoulders.” Experienced sportsmen will look for more unquestionable indications upon which to form an opinion in this respect than the very doubtful one just mentioned, which have been already noticed in the course of this article. But the Rev. Author in question makes use of several assertions respecting the hare, which, if they have no other effect, at least manifest his consummate ignorance of the subject. An experienced sportsman will be abundantly convinced of this, when he reads what the Rev. Mr. Daniel asserts in regard to the position of the hare on her seat : it is very evident the Rev. Gentleman never saw a hare on her seat.

The hare is subject to a disease very similar to the *rot* in sheep ; and numbers are sometimes found dead in a wet season, particularly on the marshy and low lands ; though, on the *mosses* (morasses) in Lancashire and the north of England, they suffer less from this disease than on low wet meadows.

Mr. White, in his History of Selbourne, gives a curious instance of a leveret being suckled by a cat. He says, a leveret was brought to him, which the servants fed with a spoon ; about the same time that the leveret arrived, the cat had kittened, and her progeny was destroyed : the leveret was soon lost, supposed to have been killed ; however, after a fortnight, Mr. White, being in his garden, observed the cat trotting up to him, making that short call that a cat uses to its kittens, and something gambolling after her, which proved to be the leveret which the cat had supported with her milk, and continued to cherish with great affection. This strange attachment (says Mr. W.) was perhaps occasioned by those maternal feelings which the loss of her own young had awakened, and by the ease she derived to herself, from having her teats, too much distended with milk, drawn by the leveret, until from habit, she became as much attached to the leveret, as if it had been her own offspring.

Dr. Darwin relates that the Rev. Mr. Sawley of Elford, near Litchfield, having taken out the young ones from a hare he had shot, which were alive, he gave them to a cat, which had just lost her kittens. The cat carried them away, as it was supposed, for the purpose of eating them ; but it afterwards appeared to have been affection, and not hunger, which had incited her, as she suckled and reared them with all possible care and attention.

A similar circumstance happened a few years ago to a Mr. Harrop of Liverpool, with this difference, however, that the foster parent was a bitch instead of a cat.

A spaniel bitch, at Dyne's Hall, in Essex, the seat of Mr. Sperling, whose whelps had just been drowned, brought home a leveret from the plantations adjoining the house, which she suckled, and for which she testified the utmost affection.

## H A R E

In covers where it is wished for hares to be preserved, no pains should be spared to render them dry at the bottom, if they are not naturally so: if the extent be considerable, walks should be cut; if small, a circular one near the side will answer the purpose. Furze covers are good preserves, particularly if mixed with broom. If the ground be prepared on purpose, spaces should be left for the purpose of sowing parsley, of which hares are remarkably fond, as already stated. No dog should be allowed to enter the cover, and all kinds of vermin should be carefully destroyed, particularly weasels, stoats, and polecats. This part of the business should be confided to a trusty and skilful gamekeeper; or to some person well acquainted with the various modes of destroying vermin.

The idea that rabbits and hares will not live together is perhaps erroneous, at least as far as relates to the generally received opinion of the antipathy which these animals naturally entertain—it is true, hares are not often found in a rabbit warren; nor are they found in great plenty perhaps where rabbits are numerous; but this, we are inclined to think, arises from some other cause than a natural aversion.

Of the susceptibility of the hare for education, we have several recorded instances, which may be relied on. In 1564, a hare was exhibited in England, which not only danced to measure, but to the astonishment of beholders, played with its fore feet upon a tabaret, and observed a correct number of strokes. Afterwards the hare fought with a dog (no doubt instructed for the purpose) when it bit with its teeth, and beat forcibly with its feet.

Still more complete was the education of the hare exhibited some years ago at Sadler's Wells, which beat a drum with its fore feet while a person carried it round the stage. It is said that the hare is partial to the sound of the drum, and that on this account she has been frequently found in the heart of various camps. Hares will frequently sit in the immediate vicinity of a dog kennel. At the latter end of the year 1822, a hare took up its position in a small orchard belonging to the writer, within ten yards of a wooden kennel, to which a dog was constantly chained. She formed several seats, all within very short distances (none exceeding twelve yards) and thus continued to reside for nearly two months, no way alarmed by the frequent barking of the dog. She was often seen, but never disturbed, and her death, which was a sort of accidental occurrence by a neighbour's greyhound, excited considerable regret.

Mr. Barlace asserts, that he saw a hare so familiar as to feed from the hand, lie under a chair in the parlour, and appear altogether as easy and comfortable as a lap dog. It sometimes went into the garden; but, after regaling itself, always returned to the house as its proper habitation. Its usual companions were a greyhound and a spaniel, both so fond of hare hunting that they were frequently questing or trying in the fields by themselves. With these dogs the hare spent the evenings; they always slept on the same hearth, and very often would rest themselves by lying upon parts of each other.

We will close the present article by the interesting account given

by Cowper, the poet, of the habits and manners of the domestic hare :—

In the year 1774, being much indisposed both in mind and body, incapable of diverting myself either with company or books, and yet in a condition that made some diversion necessary, I was glad of any thing, that would engage my attention without fatiguing it. The children of a neighbour of mine had a leveret given them for a plaything ; it was at that time about three months old. Understanding better how to tease the poor creature than to feed it, and soon becoming weary of their charge, they readily consented that their father, who saw it pining and growing leaner every day, should offer it to my acceptance. I was willing enough to take the prisoner under my protection, perceiving that, in the management of such an animal, and in the attempt to tame it, I should find just that sort of employment which my case required. It was soon known among the neighbours that I was pleased with the present, and the consequence was, that in a short time I had as many leverets offered to me, as would have stocked a paddock. I undertook the care of three, which it is necessary that I should here distinguish by the names I gave them—*Puss*, *Tiney*, and *Bess*. Notwithstanding the two feminine appellatives, I must inform you that they were all males. Immediately commencing carpenter, I built them houses to sleep in ; each had a separate apartment, so contrived that their ordure would pass through the bottom of it ; an earthen pan placed underneath each received whatever fell, which, being duly emptied and washed, they were thus kept perfectly sweet and clean. In the day-time they had the range of a hall, and at night retired each to his own bed, never intruding into that of another.

*Puss* grew presently familiar, would leap into my lap, raise himself upon his hinder feet, and bite the hair from my temples. He would suffer me to take him up and carry him about in my arms, and has more than once fallen fast asleep upon my knee. He was ill three days, during which time I nursed him, kept him apart from his fellows, that they might not molest him (for, like many other wild animals, they prosecute one of their own species that is sick), and by constant care, and trying him with a variety of herbs, restored him to perfect health. No creature could be more grateful than my patient after his recovery ; a sentiment which he most significantly expressed by licking my hand, first the back of it, then the palm, then every finger separately, then between all the fingers, as if anxious to leave no part of it unsaluted ; a ceremony which he never performed but once again on a similar occasion. Finding him extremely tractable, I made it my custom to carry him always after breakfast into the garden, where he hid himself generally under a cucumber vine, sleeping or chewing the cud till evening ; in the leaves also of that vine he found a favourite repast. I had not long habituated him to this taste of liberty, before he began to be impatient for the return of the time when he might enjoy it. He would invite me to the garden by drumming upon my knee, and by a look of such expression as it was not possible to misinterpret. If this rhetoric did not imme-

diately succeed, he would take the skirt of my coat between his teeth, and pull at it with all his force. Thus *Puss* might be said to be perfectly tamed, the shyness of his nature was done away, and on the whole it was visible by many symptoms, which I have not room to enumerate, that he was happier in human society than when shut up with his natural companions.

Not so *Tiney*; upon him the kindest treatment had not the least effect. He too was sick, and in his sickness had an equal share of my attention; but if, after his recovery, I took the liberty to stroke him, he would grunt, strike with his fore feet, spring forward, and bite. He was, however, very entertaining in his way; even his surliness was matter of mirth, and in his play he preserved such an air of gravity, and performed his feats with such a solemnity of manner, that in him too I had an agreeable companion.

*Bess*, who died soon after he was full grown, and whose death was occasioned by his being turned into his box, which had been washed, while it was yet damp, was a hare of great humour and drollery. *Puss* was tamed by gentle usage; *Tiney* was not to be tamed at all; and *Bess* had a courage and confidence that made him tame from the beginning. I always admitted them into the parlour after supper, where the carpet afforded their feet a firm hold; they would frisk, and bound, and play a thousand gambols, in which *Bess*, being remarkably strong and fearless, was always superior to the rest, and proved himself the *Vestris* of the party. One evening the cat being in the room, had the hardiness to pat *Bess* upon the cheek, an indignity which he resented by drumming upon her back with such violence, that the cat was happy to escape from under his paws and hide herself.

I describe these animals as having each a character of his own. Such they were in fact, and their countenances were so expressive of that character, that, when I looked only on the face of either, I immediately knew which it was. It is said that a shepherd, however numerous his flock, soon becomes so familiar with their features, that he can, by that indication only, distinguish each from all the rest; and yet, to a common observer, the difference is hardly perceptible. I doubt not the same discrimination in the cast of countenances would be discovered in hares, and am persuaded that, among a thousand of them, no two could be found exactly similar; a circumstance little suspected by those, who have not had an opportunity to observe it. These creatures have a singular sagacity in discovering the minutest alteration that is made in the place to which they are accustomed, and instantly apply their nose to the examination of every new object.

A small hole being burnt in the carpet, it was mended with a patch, and that patch in a moment underwent the strictest scrutiny. They seem too to be very much directed by the smell in the choice of their favourites: to some persons, though they saw them daily, they could never be reconciled, and would even scream when they attempted to touch them; but a miller coming in engaged their affections at once; his powdered coat had charms that were irresistible. It is no wonder that my intimate acquaintance with these specimens of the kind

has taught me to hold the sportsman's amusement in abhorrence ; he little knows what *amiable* creatures he persecutes, of what gratitude they are capable, how cheerful they are in their spirits, what enjoyment they have of life, and that impressed, as they seem, with a peculiar dread of man, it is only because man gives them peculiar cause for it.

That I may not be tedious, I will just give a short summary of those articles of diet, that suit them best.

I take it to be a general opinion that they graze, but it is an erroneous one, at least grass is not their staple ; they seem rather to use it medicinally, soon quitting it for leaves of almost any kind. Sow-thistle, dent-de-lion, and lettuce, are their favourite vegetables, especially the last. I discovered by accident that fine white sand is in great estimation with them ; I suppose as a digestive. It happened that I was cleaning a bird-cage while the hares were with me ; I placed a pot filled with such sand upon the floor, which being at once directed to by a strong instinct, they devoured voraciously ; since that time I have generally taken care to see them well supplied with it. They account green corn a delicacy, both blade and stalk, but the ear they seldom eat : straw of any kind, especially wheat straw, is another of their dainties ; they will feed greedily upon oats, but if furnished with clean straw never want them ; it serves them also for a bed, and, if shaken up daily, will be kept sweet and dry for a considerable time. They do not indeed require aromatic herbs, but will eat a small quantity of them with great relish, and are particularly fond of the plant called musk : they seem to resemble sheep in this, that, if their pasture be too succulent, they are very subject to the rot ; to prevent which, I always made bread their principal nourishment, and filling a pan with it cut into small squares, placed it every evening in their chambers, for they feed only at evening and in the night : during the winter, when vegetables were not to be got, I mingled this mess of bread with shreds of carrot, adding to it the rind of apples cut extremely thin ; for, though they are fond of the paring, the apple itself disgusts them. These however not being a sufficient substitute for the juice of summer herbs, they must at this time be supplied with water ; but so placed that they cannot upset it into their beds. I must not omit that occasionally they are much pleased with twigs of hawthorn, and of the common briar, eating even the very wood when it is of considerable thickness.

*Bess*, I have said, died young ; *Tiney* lived to be nine years old, and died at last, I have reason to think, of some hurt in his loins by a fall : *Puss* is still living, and has just completed his tenth year, discovering no signs of decay, nor even of age, except that he is grown more discreet and less frolicsome than he was. I cannot conclude without observing, that I have lately introduced a dog to his acquaintance, a spaniel that had never seen a hare to a hare that had never seen a spaniel. I did it with great caution, but there was no real need of it. *Puss* discovered no token of fear, nor *Marquis* the least symptom of hostility. There is therefore, it should seem, no natural antipathy between dog and hare, but the pursuit of the one

## H A R E

occasions the flight of the other, and the dog pursues because he is trained to it: they eat bread at the same time out of the same hand, and are in all respects sociable and friendly.

I should not do complete justice to my subject did I not add, that they have no ill scent belonging to them; that they are indefatigably nice in keeping themselves clean, for which purpose nature has furnished them with a brush under each foot: and that they are never infested by any vermin.

May 28, 1784.

*Memorandum found among Mr. Couper's papers.*

Tuesday, March 9, 1786.

This day died poor *Puss*, aged eleven years eleven months, He died between twelve and one at noon, of mere old age, and apparently without pain.

The underwritten epitaph on *Tiney* was by his old master.

Here lies, whom hound did ne'er pursue,  
Nor swifter greyhound follow,  
Whose foot ne'er tainted morning dew,  
Nor e'er heard huntsman's hollo'.

Old *Tiney*, surliest of his kind,  
Who, nursed with tender care,  
And to domestic bounds confined,  
Was still a wild *Jack-hare*.

Though duly from my hand he took  
His pittance every night,  
He did it with a jealous look,  
And, when he could, would bite.

His diet was of wheaten bread  
And milk, and oats, and straw;  
Thistles, or lettuces instead,  
With sand to scour his maw.

On twigs of hawthorn he regaled,  
On pippins' russet peel,  
And, when his juicy salads failed,  
Sliced carrot pleased him well.

A Turkey carpet was his lawn,  
Whereon he loved to bound,  
To skip and gambol like a fawn,  
And swing his rump around.

His frisking was at evening hours,  
For then he lost his fear,  
But most before approaching *showers*,  
Or when a *storm* drew near.

Eight years and five round rolling moons  
He thus saw steal away,  
Dozing out all his idle noons,  
And every night at play.

I kept him for his humour's sake,  
 For he would oft beguile  
 My heart of thoughts that made it ache,  
 And force me to a smile.

But now beneath his *walnut* shade  
 He finds his long last home,  
 And waits, in snug concealment laid,  
 Till gentler *Puss* shall come.

He, still more aged, feels the shocks,  
 From which no care can save,  
 And, partner once of *Tiney's* box,  
 Must soon partake his grave.

HARE HUNTING. This diversion is of very ancient date:—if we are to believe the poet, it formed one of the amusements of the mighty Nimrod:—

Bold Nimrod first the lion's trophies wore,  
 The panther bound, and lanc'd the bristling boar;  
 He taught to *turn the hare*, to bay the deer,  
 And wheel the courser in his mid career.

TICKELL.

Zenophon, who lived three hundred and fifty years before Christ, has left many observations upon hunting the hare. He says the *trail* (the track taken by the hare in going to her seat in the morning) is long in proportion to the length of the night. In the winter there is no scent early in the morning, when there is either a hoar or a hard frost. The hoar frost, by its force contracts and retains all the warm particles in itself, and the harder frost congeals them: in these cases, dogs

with the most delicate noses cannot touch, before the sun dispels the frost, or the day is advanced,—when the trail yields a scent as it evaporates. The trail is also spoiled by much dew, and by showers after a long drought; which, by extracting scents from the earth, hunt the scent of the hare until the ground is dry again. The *south winds* are injurious (he says) by spreading moisture! An English sportsman will start at such an assertion:—the song says, and says truly—

“ A southern wind, and a cloudy sky  
 Proclaim a hunting morning.”

But to proceed with Zenophon:—The north winds, if not too severe, preserve it. Rains and drizzling mists drown, and the heat of the moon, at full, destroys it; the trail is likewise the most irregular, for in the light the hares play together, and throw themselves very differently than when at feed. In the winter, autumn, and summer, the trail is for the most part straight; in the spring it is more perplexed; for, though these animals copulate at all times, they do it chiefly at that season, and their wandering on that account, in search of each other, occasions it.

The scent of a hare going to her seat, lasts longer than that of her course when pursued; in going to her form she proceeds slowly and stops often; but her course when chased, is performed running; therefore the ground is saturated with the one, and not filled with the

other. The scent is stronger in woods, whether she proceed slowly or otherwise, for there she is touched by many things. The hare makes her seat under, upon, or within any thing that covers the surface of the earth; in spring she prefers cultivated places to the mountains; but, wherever seated, there she continues while the hounds are trailing to her, unless she has been much disturbed in the night, when she will sometimes move. The scent of young hares is stronger than of those full grown, on account of the weakness of their limbs suffering their whole body to touch the ground. The hares of the mountains are swifter than those bred in the plains; the marsh hares are the slowest of any; those hares which wander in all places are the most subtle and difficult to pursue: those of a year old, will run the first ring swiftly, but

not at all afterwards, being very active, but weak. Those that are met with in open situations, run the longest, on account of their being used to the light; those in woody places, the reverse, being hindered by the darkness.

When the hare is started, there should be no hallooing, lest the hounds, being thus made too eager, should not stoop to the scent. Hares are most conspicuous when running over ploughed land. If they perceive the dogs, they stop, and, sitting on their breech, raise themselves up and listen if they hear any opening of the hounds near them, and then turn from the spot where they hear it; but if there be no noise, they will, of their own accord, return by the same track to where they were first disturbed from. Their eyes project, and their eye-lids are not sufficiently long to protect the ball, which, added to the quantity of sleep the hare takes, renders her sight indistinct; the swiftness of its pace contributes also to dazzle it; for a hare that is pressed by the dogs passes by every object before she perceives what it is, on which account she often runs against many things.

Zenophon's formation of the hare is not worth recapitulation, on account of what has been already stated in the preceding article. But being so constructed, he observes, it is impossible but that the hare must be strong, agile, and light; as a proof of her lightness, when going without being alarmed, she always leaps, throwing the hinder beyond the fore feet; and she runs in that manner, as is manifest in snow. Her tail is inconvenient in running, being unable, on account of its shortness, to guide her body; but she does that with either of her ears; and when nearly taken by the dogs, she lays down the ear on the side whence she apprehends the danger, by which means she turns instantly, throwing the dogs that are dashing at her a great way behind.

When hunting in cultivated lands, the sportsman should avoid injuring the fruits of the earth that are in season; and where no game is found all the hunting apparatus should be entirely taken away.

Hounds ought to be hunted every day, if well and the weather suitable; but should never be taken out to hunt, unless they eat their food heartily, their refusal being a sign of ill health. A high wind is unfavourable to hounds, as it dissipates the scent, and prevents their hearing each other; neither can the toils or nets stand; they should never be suffered to hunt

foxes, as that does them the greatest injury, and renders them unsteady to their own game.

The places of hunting should be frequently changed, in order that the dogs and the sportsman himself may obtain a thorough knowledge of the country. An early hour is necessary, that the trail may not be gone. The huntsman's dress should be light, and he should have a pole in his hand, the man who carries the nets following him; and they should proceed silently, lest the hare should steal away before the nets and toils are placed.

The best time for breeding hounds is in winter, when the labours of the chase are over, on account of the quiet of that season, and the approach of spring, which is the time of the year best agreeing with the growth of dogs. The bitches should be shut up with the best dogs, and whilst in whelp should not often be taken out, lest the exertion should injure them.

When the whelps can run about, they should have nothing but milk for the first year; for the filling them with too heavy food will distort their legs, fill their bodies with diseases, and hurt their insides. The bitch puppies should be first taken out to hunt at eight months old, and the dogs at ten; they should not be let loose during the trail; but, being controlled by long leather slips, should be allowed to follow the hounds that were trailing.

When the hare was started, if the whelps promised to have much foot, they were not to be slipped immediately, but after the hare was got out of sight; for those that are high mettled and swift of foot, if let go while the hare is in view, will be apt to strain themselves before their limbs have sufficient strength. If slow, they were to be slipped immediately; for, having no hopes of catching their game by speed, they will not be so eager, but may be permitted to follow by foot until the hare is started again, which, if taken, the young hounds should be permitted to tear. When they will not keep the scent, and run straggling about, they should be called back until they are taught to find the hare, lest, being used to hunt without order, they become skirthers, and skirting is a fault which hounds should never be suffered to contract. When they are hungry, the huntsman should feed them himself: they will disregard the person who feeds them when they are not hungry; but will diligently follow him who attends and prepares their food when they are so.

Descending to writers of a date less remote, we find Mr. Blome, after some prefatory remarks not necessary in this place, observes, that the season commences in September, and that an expert huntsman may distinguish the sex, strength, and age of his game by the following signs :—when a hare rises out of her seat, if she erects her ears, and at first runs slowly with her scut cast over her back, she is surely old and crafty. When a hare is hunted to her form along the hard highways, and feeds far away from cover, and that the doublings and crossings are wide and large, it is a buck; as she does generally keep close to the side of some cover, and when going to feed in the corn fields, seldom cross over the furrows, but follow in the track of them; when hunted, they turn frequently, use many stratagems, and rarely leave the country round their seats; while the buck, after two or three turns about his form, runs straight forward four or five miles, and then probably squats in some place where he has before preserved himself. A buck hare may also be known at starting by the whiteness of his hinder parts.

The chase of the hare, continues Mr. B. makes the best diversion of all chases, is procured with less expense as to the hunting establishment, and she shews more cunning and subtlety to avoid the hounds: amongst the many shifts of the hare, the following is remarkable :—a hare that is run in or immediately after rain, will not take to the woods on account of the wet that hangs on the small boughs, but will often squat at the edge of a cover, and as soon as the hounds have overrun the scent, will return to her seat; to prevent which, unseen, the huntsman should keep at a distance from the wood which she seems to enter, that he may halloo off the hounds, and again lay them upon the scent, before the hare is too long gone.

Mr. B. entertained some strange notions respecting the entering of young hounds. He says, it is not advisable to enter young hounds in the mornings, because of the dew and moisture of the earth; for then, when wanted to hunt in the heat of the day, especially in warm weather, or when the wind has dried the ground, they will betake themselves to shady places to rest and sleep; therefore, the best time for entering hounds is in the heat of the day, and about October and November, the weather being then temperate, and young hares that have

not been hunted are then more easily taken for their encouragement. He adds a further caution—never at the entering of young hounds, to help them to kill the hare with greyhounds, which will prevent the hounds from putting their noses to the ground, or trying to hunt for themselves.

Hounds, after two years old, should be hunted three times a week, if they feed well, and may be kept out the greatest part of the day to try their stoutness.

The hare should be sought according to the season of the year :—if it be spring, upon fallows or green corn; during the autumn, in stubbles and turnips; in winter, they will seat themselves near houses, in brambles and tufts of thorns.—The beating her from her seat is recommended in preference to trailing her from her feed to her form.

Great exactness was to be observed at the first entering of hounds; they were not to be repeatedly uncoupled on the same sort of ground, lest by being uncoupled constantly in an open field, they would be at a loss what to do when turned into a cover.

It was a received opinion, that, according to the places where hounds were first entered, they would continue afterwards to shew a preference; as, for instance, if entered in a champaign country, they would always hunt better there than in covers, marshy or mountainous grounds: it was therefore recommended to accustom them to all kind of countries that they might become perfect in all.

Some of the early sportsmen would not suffer the huntsman to halloo when the hounds were at fault, nor to be assisted in any way; on the contrary, the dogs were suffered to hunt it out by themselves: which was considered a sure way of ascertaining the goodness of the hounds. There were not wanting others, however, who deemed it right to take all advantages and kill the hare as soon as possible.

An old author observes,—if there be any hound which has found the trail of a hare, where she relieved that night, let the huntsman then forbear being over hasty, but let the hounds make it out of themselves; and when he perceives that they begin to draw in together, and call on freshly, then let him encourage them, especially that hound which hunts best, frequently calling him by his name.

A hare, he continues, leaves better scent when she goes to relief than when she goes towards her form: for when she

relieves in the field, she couches her body low upon the ground, passing often over one piece of ground to find where lieth the best food, and thus leaveth the better scent, crotting (dunging) also sometimes.

Besides, when she goes to her form, she commonly takes the highways, doubling, crossing, and leaping as lightly as she can ; in which places the hounds can have no scent by reason of the dust, &c. The hares will squat also by the sides of the highways, and therefore the huntsman should well beat the sides of the highways.

Now, having found where a hare hath relieved in some pasture or corn field, then must you consider the season of the year, and what weather it is. For if it be in the spring time or summer, a hare will not then sit in the bushes, because they are frequently offended with pismires, snakes, and adders, but will sit in corn fields and open places.

When a hare is started on foot, then step in where you saw her pass, and halloo in your hounds until they have all undertaken it, and go on with it in full cry : then recheat to them with your horn, following fair and softly at first ; making neither too much haste, nor too much noise with your horn or voice ; for, at the first, hounds are apt to overshoot the chase through too much heat. But having ran the space of an hour, and that you see the hounds are well in with it, sticking well upon it, then you may come in nearer with the hounds, because by that time their heat will be cooled, and they will hunt more slowly. But, above all things, mark the first doubling, which must be your direction for the whole day ; for all the doublings that she shall afterwards make will be like the former ; and according to the policies that you shall see her use, and the place where you hunt, you must make your compasses, great or little, long or short, to help the defaults, always seeking the moistest and most commodious places for the hounds to scent in.

The plan which some of the ancient sportsmen adopted in rewarding the hounds clearly shews the very imperfect notions which they entertained of this part of the business. The hare, when killed, was to be laid on the grass and bayed by the hounds ; it was to be skinned before them, and after the gall and lights were taken away, which were supposed peculiarly liable to make the hounds *sick*, the huntsman, who carried a wallet,

containing bread cut into small pieces, dipped them in the blood, and, with the entrails, gave them to the hounds : the hare was afterwards distributed, and if any young hound was fearful to come amongst the rest, he had the head given him by himself. After which, the hounds had bread given them to prevent *sickness*. It was supposed that the flesh of an old hare was not fit for human food, being hard of digestion, and apt to produce melancholy ; leverets, however, were allowed to be nourishing.

Thus far the notions of old sportsmen, which may be considered as obsolete. We now bring under consideration the ideas of one who published his ex-cogitations in 1733 ; and although quaintly written, and displaying much self-conceit in the author, are nevertheless characterised by much more than ordinary discernment and reflection.

The author in question observes, there is something noble and heroic in hunting the wild boar, the tiger, and the lion ; but we inhabit an island where art and activity are more requisite to the huntsman than strength of body, and where safety must compensate for want of glory.

The principal games of Great Britain (says he) are the deer, the fox, the hare, the otter, the badger, and the martin ; though the three last of these would hardly deserve the honour of being hunted, were they not in season in the spring of the year, when the poor hare ought to be in peace to multiply her species, and were not our young gentlemen contented to play at a small game rather than stand idle.

The stag, he admits, is a noble prize ; and as the taking it requires a large pack of dogs, the very best horses, and a great expence, it is calculated for the nobility and men of princely fortunes only. The pursuit after the fox is also violent, and rather fit for those youthful heroes, who glory in breaking the hearts of their horses, and venturing their own necks.

The author in question further observes — Every hare is no sooner started than she seems immediately to form a scheme, and to take into it the gravity of the air, the position of the wind, the difference of the soil, the succour of a flock of sheep, and every other accident or advantage that may be most likely to baffle her adversaries, and favour her escape. Nor is the experienced hound less acute and crafty, to stop at every double in order to apprehend her where she squats ; to try

every bye-path, gate, gutter hole, to round it on the side where she seems to bend ; to proportion his speed to every degree of alteration of the scent, or sinking of the foe. He seems also, with no less curiosity, to distinguish the scent he is engaged in from any new offer, as well as to discern and pick it out as often as she repeats the foiled path.

It is very common for a hare to run a mile or two forward, and then, making a small ring, to fly back in the same track, whilst her enemies are puzzling at the head of her works : and I have been several times an eye witness (says he) of her beating about, and thrusting out a fresh hare in her place, and then saving herself by a swift retreat, and two or three large leaps, the better to impose upon the eager dogs. I have also seen an old dog, on the like occasion, standing to his first scent, looking over his shoulder, and, as it were, scolding at his headless juniors for going on so eagerly, or for changing their game. —A hundred more of this sort of observations, you may hear from any old weather-beaten huntsman, over a bottle of *October*.

The author, whose opinions we have latterly been quoting was an enthusiastic admirer of hare hunting, and indeed many of the ancient sportsmen preferred it to any other chase ; but they had no idea of that perfection which fox hunting has attained since their time. Their horses were very inferior to those of the present day ; and unless the horses, and hounds too, are of the best possible description, fox hunting must be very vexatious and tiresome, and will generally end in disappointment. So the sportsmen of the ancient school no doubt found it ; on which account it was not much practised or studied by them ; and, in consequence, the accounts which they have left behind them, say but little on the subject, and that little is neither instructive nor satisfactory.

On the subject of hare hunting, Beckford observes, that, though he kept harriers for many years, he never was a hare hunter from inclination. “ I followed the diversion (he continues) more for air and exercise than for amusement ; and if I could have persuaded myself to ride on the turnpike road to the third mile stone and back again, I should have thought I had no need of a pack of harriers.—Excuse me, brother hare hunters ! (he exclaims) I mean not to offend ; I speak only of the country where I live. The hare hunting there is so bad, that, did you know it,

your wonder would be how I could have persevered in it so long, not that I should forsake it now. I respect hunting, in whatever shape it appears ; it is a manly and a wholesome exercise, and seems by nature designed to be the amusement of a Briton.”

Beckford's opinion is, that the hound most likely to shew sport in hare hunting is one bred between the large slow hunting harrier and the little beagle ; one is too dull, too heavy, and too slow ; the other, too lively, too light, and too fleet. The first have most excellent noses, and will kill their game at last, if the day be long enough. The others, on the contrary, fling and dash, and are all alive ; but every cold blast affects them (says he) ; and if the country is deep and wet, it is not impossible but some of them may be drowned. “ My hounds were a cross of both these kinds, in which it was my endeavour to get as much bone and strength in as small a compass as possible. It was a difficult undertaking. I bred many years, and an infinity of hounds, before I could get what I wanted. I at last had the pleasure to see them very handsome, small, yet very bony ; they ran remarkably well together ; ran fast enough ; had all the alacrity you could desire, and would hunt the coldest scent. When they were thus perfect, I did as many others do, I parted with them.”

The huntsman to a pack of harriers, Beckford says, should not be young ; he should be quiet and patient ; for patience indeed he should be a very grizzle ; and the more quiet he is the better. He should have infinite perseverance, for a hare should never be given up whilst it is possible to hunt her ; she is sure to stop, and therefore may always be recovered.

The whipper-in should be like the second whipper-in to a pack of fox-hounds ; merely the stable boy, who is to follow the huntsman ; in fact, he should not even stop a hound, or crack a whip, without the huntsman's order. Much noise and rattle are directly contrary to the first principles of hare hunting, which is to be perfectly quiet, and let the hounds alone. There are perhaps few packs of harriers so good as those kept in towns, and which have no professed huntsman to follow them. If they have no one to help them, they have at the same time no one to spoil them, which for hare hunting is very material. Hounds, however, if left entirely to themselves are apt to contract the fault of *running the heel*. Hounds are naturally fond

of scent; if they cannot carry it forwards, they will turn and hunt it back again. In this particular instance, harriers should be mildly checked; for, as it is almost an invariable rule in all hunting to make the head good, the dogs should be encouraged to try forward first; which may be done without taking them off their noses, or without the least prejudice to their hunting. If trying forward should not succeed, they may then be suffered to try backward, which they will be all ready enough to do; as they are sensible how far they brought the scent, and where they left it.

Harriers, like all other hounds, to be good should be kept to their own game. Hounds cannot be perfect, unless used to one scent, and one style of hunting. To run a fox with harriers makes them wild, and teaches them to skirt. The high scent which a fox leaves, the straightness of his running, the eagerness of the pursuit, and the noise which generally accompanies it, all contribute to spoil a harrier.

It is a fault in a pack of harriers to go too fast; for a hare is a little timorous animal that we cannot help feeling some compassion for, at the very time when we are pursuing her destruction: scope should be given for all her little tricks, nor should she be over matched and foully killed. Instinct instructs her to make a good defence, when not unfairly treated; and, as far as her own safety is concerned, she will display more cunning than a fox, and will make many shifts to save her life far beyond all his artifice.

Those who like to rise early will experience much amusement in seeing the hare trailed to her form; and it is of great service to harriers; it also shews their goodness to the huntsman more than any other hunting, as it discovers to him the hounds which have the tenderest noses. "But I confess (says Beckford) I seldom thought it worth while to leave my bed a moment sooner on that account; I always thought hare hunting should be taken as a ride after breakfast, to get us an appetite to our dinner. If you make a serious business of it, I think you spoil it."

When hounds go out late, hare finders become necessary: it is pleasing to know where to go immediately for diversion, and not to beat about for hours before a hare is found. It is more material with regard to the second hare than the first; since, if you are warmed with your gallop, the waiting long in the cold afterwards, is disagreeable, if not dangerous. Yet, it must be admitted, that hounds hunt the game

which they find themselves with more spirit, and the sportsman himself feels a pleasure in expectation which no certainty can give. Further, hare finders make hounds idle, as well as wild. Beckford says, "mine knew the men, as well as I did myself, could see them almost as far, and would run, full cry, to meet them."

Hare finders are of one great service—they prevent hounds from chopping hares, which otherwise they would not fail to do. "I had in my pack, one hound in particular that was famous for it; he would challenge on a trail very late at noon, and had as good a knack of chopping a hare afterwards; he was one that liked to go the shortest way to work, nor did he choose to take more trouble than was necessary."

It is said by those who profess to be deeply skilled in the business, that if you make forms hares will sit in them; and Beckford was informed that this was a common practice of the shepherds on the Downs of Wiltshire: and that by making them on the sides of hills, they could tell at a distance, whether there were hares in them or not. There are many strange tales told on sporting subjects, and these last mentioned are given as the reports of others, and not as matters which have actually fallen under the observation of the writer, or what he implicitly believes.

"The talent of hare finding (says Beckford) is certainly of use, and the money collected for it, when given to shepherds, is money well bestowed by a sportsman, as it tends to the preservation of his game; yet, I think, when it is indiscriminately given, hare finders are often too well paid. I have known them frequently get more than a guinea for a single hare. I myself have paid five shillings in a morning for hares found sitting. To make our companions pay dearly for their diversion, and oftentimes so much more than it is worth; to take from the pockets of men who oftentimes can ill afford it, as much as would pay for a good dinner afterwards, is, in my opinion, a very ungenerous custom; and this consideration induced me to collect but once, with my own hounds, for the hare finders. The money was afterwards divided amongst them; and, if they had less than half-a-crown each, I myself supplied the deficiency.—An old miser, who had paid his shilling, complained bitterly of it afterwards, and said, '*he had been made to pay a shilling for two penny-worth of sport.*'"

When a hare is found the sportsmen cannot be too quiet: the hare is an animal so very timorous, that she is frequently headed back, and the hounds are liable to overrun the scent at every instant. It is advisable, therefore, to keep sufficiently behind them so as to allow them room to turn as soon as they perceive that they have lost the scent; and, if treated in this manner, the dogs will seldom overrun it much. The hounds in fact, through the whole chase, should be left almost entirely to themselves, nor should they be hallooed too much: when the hare doubles, they should hunt through those doubles; nor is a hare hunted fairly, when hunted otherwise. The dogs should follow her every step she takes, as well over greasy fallows, as through large flocks of sheep; nor should they ever be cast, but when nothing can be done without it.

“ I know a gentleman (says Beckford) a pleasant sportsman, but a very irregular hare hunter, who does not exactly follow the method here laid down: as his method is very extraordinary, I will re-

late it to you. His hounds are large and fleet; they have at times hunted every thing—red deer, fallow deer, fox and hare; must in their nature have been most excellent; since, notwithstanding the variety of their game, they are still good. When a hare is found sitting, he seldom fails to give his hounds a view; and as they all halloo, and make what noise they can, she is half frightened to death immediately. This done, he sends his whipper-in to ride after her, with particular directions not to let her get out of his sight; and he has found out that this is the only proper use of a whipper-in. If they come to a piece of fallow or a flock of sheep, the hounds are not suffered to hunt any longer, but are hallooed as near to the hare as possible; but by this time the poor devil is near her end, which the next view generally finishes; the strongest hare, in this manner, seldom standing longer than twenty minutes; but my friend says, a hare is good eating, and he therefore thinks he cannot kill too many of them.”

When a hare is found, Somerville observes:—

At distance draw thy pack; let all be hush'd,  
No clamour loud, no frantic joy, be heard,  
Lest the wild hound run gadding o'er the plain  
Untractable, nor hear thy chiding voice.  
Now gently put her off:—see how direct  
To her known meuse she flies! Here, huntsman, bring  
(But without hurry) all thy jolly hounds,  
And calmly lay them on. How low they stoop,  
And seem to plough the ground; then all at once,  
With greedy nostrils, snuff the fuming steam  
That glads their fluttering hearts. As winds let loose  
From the dark caverns of the blustering god,  
They burst away, and sweep the dewy lawn.

The natural eagerness of the hounds when the hare is first found, will frequently carry even the best of them wide of the scent, which too much encouragement, or pressing too close upon them, may continue beyond all possibility of recovery; this should be always guarded against. After a little while, they become settled to their scent. They may then be approached nearer; leaving, however, room at all times sufficient for them to turn,

should they overrun the scent. On the high roads and paths, the scent is always doubtful, and little should be said to the hounds; but when a hit is made on either side, hallooing will do harm.

A hare generally describes a circle as she runs; large or less, according to her strength, and the openness of the country. Where there is much cover, the circle is generally small, and the task of the hounds thereby rendered extremely difficult.

“ Huntsman! her gait observe: if in wide rings  
She wheels her mazy way, in the same round  
Persisting still, she'll foil the beaten track.  
But if she fly, and, with the fav'ring wind  
Urge her bold course, less intricate thy task:  
Push on thy pack.”

SOMERVILLE.

Besides running the foil, hares frequently make doubles, which is going forward to tread the same steps back again, on purpose to confuse the pursuers; and the same manner in which they make the first double, they generally continue, whether long or short. This information therefore, if properly attended to by the huntsman, may also be of use to him in his casts.

When a hare makes a double on a high road or a path, and then leaves it with a spring, it is frequently the occasion of a long fault. The spring which a hare will make, on these occasions, is hardly to be credited, any more than is her ingenuity in making it—both are wonderful!

“ ————— Let cavillers deny  
That brutes have reason; sure 'tis something more:  
'Tis Heaven directs, and stratagems inspire,  
Beyond the short extent of human thought.”

SOMERVILE.

After running a path a considerable way, a hare will frequently make a double, and there stop till the hounds have passed her: she will then steal away as secretly as she can, and return the same way she came. This is the greatest of all trials for the hounds. It is so hot a foil, that, in the best packs, there are not many hounds that can hunt it; those hounds must be followed which can, and she may be perhaps recovered. It may not be amiss here to remark, that many of the modern harriers are bred *too high*; or, in other words, for the sake of increasing the speed, they are bred tall and light; and, while all possible pains have been bestowed to accomplish this object, the most essential qualification in a hound was never once considered—we mean the excellence of the olfactory organs. The modern fashionable harrier is a sort of small greyhound; and, like the dog last mentioned, has a narrow contracted head; such harriers are considered handsome by modern taste, though we will venture to assert, without the fear of contradiction, that no narrow headed dog can possibly possess olfactory organs in a superior degree, or manifest what some sportsmen call a tender nose.—(See the article HOUND, and also the article SCENT). Lord Molyneux, a year or two back, procured a pack of beagles, with which he *attempted*

to hunt hares—we say, *attempted*, because these little dogs could seldom make any thing of it; unless, indeed, they had every possible advantage of atmosphere and country. His Lordship very soon grew tired of them and gave them up. They were called pretty little dogs, and so they appeared to superficial observation; but, after having followed the chase for more than thirty years, we must honestly confess, that no hound appears handsome in our eyes unless his qualifications, displayed in the field, are such as to entitle him to our regard. When a hare runs the foil, it is a mere accident, if she be hit off again by many of what are called the high-bred harriers. Dogs of this description will run fast when the game is pointed out to them, and while they can see it; but they cannot hunt a cool scent; and even under any circumstances, it is a thousand to one if the first fallow does not stop them. So conscious indeed are such dogs of their own incapacity, that on coming to a fallow field, or any other place of difficulty, they throw up their heads, and stare about, waiting for a distant halloo, or something of the sort, by which to direct their next movements.

But to return.—When the scent lies bad in cover, the hare will sometimes hunt the hounds.

“ ————— The covert's utmost bound  
Slily she skirts; behind them cautious creeps,  
And in that very track, so lately stain'd  
By all the steaming crowd, seems to pursue  
The foe she flies ————— ”

SOMERVILE.

When harriers are at a check, the huntsman should stand as still as possible: hounds lean naturally towards the scent; and if not a word be spoken to them, it

is ten to one but they will soon recover it. “ If (says Beckford) you speak to a hound at such a time, calling him by his name, which is too much the practice, he

seldom fails to look up in your face, as much as to say, *what the deuce do you want?*—when he stoops to the scent again, is it not probable he means to say, *you fool you, let me alone?*”

When the dogs are at fault, not a word should be said by any of the sportsmen, nor should any one stir. “A neighbour of mine (says Beckford) was so truly a hare hunter in this respect that he would not suffer any person to speak a word, when his hounds were at fault:—a gentleman happening to cough, he rode up to him immediately and said, ‘*I wish, Sir, with all my heart, your cough was better.*’”

On a good day, good hounds seldom give up the scent a head; if they do, there is generally an obvious reason for it; this observation a huntsman should always make—it will direct his cast. If he knows his business, he will be attentive as he goes, not only to his hounds, nicely observing which have the lead and the scent they carry, but also to the various circumstances that are continually happening from change of weather and difference of ground. He will also be mindful of the distance the hare keeps before the hounds, and of her former doubles, and he will remark what point she makes to. All these observations will be of use should a long fault make his assistance necessary; if the hare has headed back, he will carefully observe whether she met any thing in her course to turn her, or turned of her own accord. When he casts his hounds, he should begin by making a small circle; if that will not do, he should try a larger; afterwards he may be at liberty to make any cast he thinks proper. As a hare generally revisits her old haunts, and returns to the place where she was first

found, if the scent is quite gone, and the hounds can no longer hunt, *that* is as likely a cast as any to recover her. But the huntsman should remember this in all his casts, that the hounds are not to follow the heels of his horse, nor are they to carry their heads high and noses in the air. At these times they must try for the scent, or they will never find it, and he is either to make his cast slow or quick, as he perceives his hounds try, and as the scent is either good or bad.

A huntsman should also be as careful as possible to prevent his hounds chopping hares. Huntsmen like to get blood at any rate; and when once hounds have been used to it, they are always on the look out for opportunities. Beckford observes, “I remember in a furzy country, that my hounds chopped three hares in one morning; for it is the nature of these animals either to leap up before the hounds come near them, and *steal away*, as it is called; or else to lie close till the dogs put their very noses upon them. Hedges also are very dangerous; if the huntsman beats the hedge himself, which is the usual practise, the hounds are always upon the watch, and a hare must have good luck to escape them all. The best way to prevent it is to have the hedges well beaten at some distance before the hounds.”

Hares seldom run so well as when they do not know where they are.—They run well in a fog, and generally take a good country. If they set off down the wind, they seldom return—the hounds then cannot be pushed on too much. When the game is sinking, you will perceive the old hounds get forward: they, then, will run at head. Thus sings Somerville:—

“Happy the man, who, with unrivalled speed,  
Can pass his fellows, and with pleasure view  
The struggling pack; how in the rapid course  
Alternate they preside, and jostling push  
To guide the dubious scent; how giddy youth  
Oft babbling errs, by wiser age reproved:  
How, niggard of his strength, the wise old hound  
Hangs in the rear, till some important point  
Rouse all his diligence, or till the chase  
Sinking he finds; then to the head he springs,  
With thirst of glory fir’d, and wins the prize.”

Babblers should never be kept; for, although the rest of the pack soon find them out, and do not pay attention to them, yet it is unpleasant to hear their noise; nor are they fit companions for the rest.

No hound should be kept that runs false; the loss of one hare is more than such a hound is worth.

Hounds should sometimes have a hare given them, particularly young hounds; though in respect to blood being indis-

pensible to hounds, we refer the reader to what has been said under the article **FOX HUNTING**.

Beckford very pointedly says, "It is too much the custom first to ride over hounds, and then to cry *'ware horse*. I have known many a good hound spoiled by it. In open ground, speak to them first; you may afterwards ride over them, if you please; but in roads and paths, they frequently cannot get out of your way; it surely then is your business to stop your horse, or break the way for them, and the not doing it, give me leave to say, is absurd and cruel; nor can that man be called a good sportsman who thus wantonly destroys his own sport. Indeed, good sportsmen seldom ride on the line of the tail hounds."

Warren hares, which are caught, and turned down before hounds seldom shew much sport. When they are turned down, they should not have much time, but the hounds should be laid on as soon as they are out of view; or they will very likely stop, which is often fatal. Views are at all times to be avoided, but particularly with trap hares; for as these know not where they are, hounds have too great an advantage over them. It is best to turn them down the wind; they hear the

hounds better, and seldom turn again. These hares run straight and make no doubles; leave a strong scent, and have other objections in common with animals turned out before hounds: they will shew but little hunting. The hounds should be hunted much in the same manner as a pack of fox-hounds, as a trap hare runs much in the same manner as a fox, and will even top the hedges.

Beckford finishes his remarks on hare hunting by observing, "It is very good diversion in a good country; you are always certain of sport; and if you really love to see your hounds hunt, the hare, when properly hunted, will shew you more of it than any other animal,"

Hares should never be hunted beyond the early part of March; and indeed, if the season be forward, they should not be hunted in March at all."

Of all chases, none affords so much pleasure to the pedestrian sportsmen as the pursuit of the hare; as these animals run in circles, and generally return to their old ground, by which means they are enabled to keep, for the most part, in sight of the hounds: it is in fact charming diversion, and admirably described by the poet of the chase:

"Hark! from yon covert, where those towering oaks  
Above the humble copse aspiring rise,  
What glorious triumphs burst in every gale  
Upon our ravish'd ears! the hunter's shout,  
The clanging horns swell their sweet-winding notes,  
The pack, wide opening, load the trembling air  
With various melody: from tree to tree  
The propagated cry redoubling bounds,  
And winged zephyrs waft the floating joy  
'Thro' all the regions near: afflictive birch  
No more the school boy dreads; his prison broke,  
Scampering he flies, nor heeds his master's call;  
The weary traveller forgets his road,  
And climbs the adjacent hill; the ploughman leaves  
Th' unfinished furrow; nor his bleating flocks  
Are now the shepherd's joy! men, boys, and girls,  
Desert th' unpeopled village; and wild crowds  
Spread o'er the plain, by the sweet phrenzy seiz'd."

**HARE NETS.** These are of two sorts. The first has already been described under the head of **GATE NET**; the other is called a purse net, and is made something in the form of a cabbage net, but larger. The purse net may be very successfully used instead of the wire snare, with this difference, however, that the hares are caught alive, and they are even more certain than the wire snare, and more easily

set at the meuses or runs. In the day time, the poacher finds the purse net a very convenient and a very ready instrument for his nefarious purpose. He will place them in a very few minutes round a plantation where hares perhaps are numerous, and then by going in and disturbing the cover, even without a dog, he will completely accomplish his purpose. The hares take the alarm, and in threading

the meuses, throw themselves into the nets, where they become entangled.

**HARE WARREN.** An inclosure for the purpose of keeping hares; and now very little used.

**HARE PIPES** were instruments constructed so as to imitate the whining whimper of a hare. They were formerly used by poachers; but have given place to an improved system of depredation.

**HARK FORWARD!** is a sporting exclamation, and affords to distant sportsmen information that the hounds are ahead, and are right.

**HARNESS.** All the accoutrements of an armed horseman; also, all manner of trappings, furniture, collars, &c. fitted to horses or other beasts for drawing.

**HARRIERS.** Hounds used in the pursuit of the hare.—See the article **HOUND**.

**HART.** The male of the red deer, generally called the stag, to which article we refer the reader. Formerly the word hart was used in all Forest Laws and Records.

**HART ROYAL.** In early times, when the king lost a stag, open proclamation was made in all towns and villages near where the deer was supposed to remain, that no person should kill, hunt, or chase him, that he might safely return to the forest again, and the foresters were ordered to harbour the said hart, and by degrees to bring him back to the forest, and that deer was ever after called a *hart royal proclaimed*.

*White Hart Silver*, as it is called, was a heavy fine laid on some lands, near the Forest of Blackmore, Dorsetshire; the proprietor, T. de la Lynde, a Dorsetshire Baron, in the time of Henry III. having destroyed a white hart which had afforded that prince much amusement (probably had been proclaimed); an acknowledgment of which has been paid into the exchequer so late as the reign of Elizabeth.

**HAUNCH AND HIP** of a horse, have been hitherto used in a similar sense: nice observers might say one begins where the other ends, or that one immediately succeeds the other. The haunch is that part of the hind quarter extending from the point of the hip-bone, down the thigh to the hock; but as it is a part well known, and but little subject to partial disease or accident, it lays claim to no particular description. The term of "putting a horse upon his haunches," implies the making him constantly fix the principal weight of the frame upon his hind quar-

ters, by which practise he bears less upon the bit, and becomes habitually light in hand. Horses hard in mouth, and heavy in hand, frequently undergo the ceremony of being put upon their haunches in the trammels of a riding school, where, by too severe exertions, sudden twists and strains are sustained in the hocks, which terminate in curbs and spavins.

**HAW.** The *membrana nictitans* of an animal. Its appearance over the eye of a horse, when affected with inflammation, has led to an erroneous opinion, that it is a diseased production, and should be extirpated. Accordingly, we find directions for that purpose in many of the books of farriery. Thus Gibson says, "Haws grow sometimes in eyes that are not naturally bad, after surfeits and cold, but moon-blind horses indeed are seldom without them; and wherever this symptom appears, that the haw grows large and spongy, and derive a drain of humours upon the eye, the operation becomes necessary, and is performed by taking hold of the membrane with a small hook, and cutting off so much of the caruncle as looks moist and spongy, with part of the membrane and gristle that make a pressure on the eye. When this operation is well performed, it does great service, and often recovers horses that are not subject to cataracts. The operation is easy, and what almost every farrier pretends to; but the farriers are apt to cut off too much of this substance, and by that means weaken the eye;" and indeed, when the operation is skilfully performed, the animal generally becomes blind.

**HAWKS AND HAWKING.** See **FALCONRY**.

**HAY** is that general and well known article, grass, cut in its most luxuriant and nutritious state, during the months of June and July; when the succulent parts tending most to putrefaction, being extracted by the powerful rays of the sun, it acquires (if the season should prove dry and favourable for the operation) a degree of fragranciness nearly equal to a collection of aromatic herbs. Hay, in this state, is the most attracting aliment to horses of every description, and so truly grateful to the appetite, that it is often accepted when corn is refused.

**HAYS.** Large nets for taking rabbits, in or near a warren.

**HAYWARD OR HAWARD.** A keeper of the common herd of cattle of the town, who is to look that they neither break nor crop the hedges of inclosed lands, and is

sworn in the lord's court for the performance of his office.

**HAZARD** is a game of chance : it is played with a box and pair of dice, and is of considerable antiquity.

**HEAD OF A HORSE.** See **CONFORMATION**.

**HEADS OF DEER.** All those in deer that have double burs on the antlers; royals and croches turned downwards, are properly termed heads.

Heads of so many croches : all heads of deer, which do not bear above three or four, the croches being placed aloft, all of one height, in form of a cluster of nuts, generally go by this name.

**HEAD-STALL** is the part of a cave-son, bridle, halter, &c. which passes round, and on each side the head of the horse, and to which the reins of either are affixed.

**HEARSE.** A hind in the second year of her age.

**HEAT.** A term used by gentlemen of the turf, to denote a certain distance which a horse runs on the course. A race may consist of one or more heats.

**HEATH FOWL.** See the article **GROUSE**.

**HEAVIER.** A stag deprived of his testicles by castration is then called a heavier, which operation was occasionally performed that a supply might not be wanting for the chase during the rutting season. At this period the stag is perpetually ranging from one hind to another, for three weeks or longer; without allowing himself food, sleep, or rest. Towards the termination, he becomes lean and languid, and withdraws himself to seek food and repose. At this period, he is so ill adapted for sport with the hounds, that the operation of castrating was adopted as an alternative to the temporary suspension of the royal chase.

It is said that if a stag undergoes this operation when his horns are shed, they never grow again; on the contrary, if it is performed while the horns are in perfection, they will never exfoliate; and it is remarkable, that being deprived of only *one* testicle, the horn will not regenerate on that side, but will continue to grow, and to be annually shed, on the other side, where the testicle has not been taken away.

**HEAVY IN HAND.** A horse is said to be heavy in hand, when, from want of spirit, he goes sluggishly on, bearing his whole weight upon the bit; as if the hand of the rider alone prevented his pitching

upon his head. Horses of this description should be frequently made to feel the curb and the spur.

**HEEL OF A HORSE.** The lowest hind-part of the foot, comprehended between the quarters, and opposite to the toe.

**HEELER** is the person who affixes the spur to the heel of a game cock, when taken from the pen previous to his being carried to the cock-pit to fight his battle. A hard-hitting cock, who is perpetually fighting with effect, is also called a heeler.

**HEINUSE.** A roebuck of the fourth year.

**HELPS OR AIDS** are terms appertaining solely to the manege and riding-school. Professors technically describe seven helps necessary to complete the lesson given to a horse; as the voice, whip, bit, calves of the legs, the stirrups, the spur, and the ground.

**HEROD, KING.** A bay horse, foaled in 1758, bred by his Royal Highness William, Duke of Cumberland, and sold to Sir John Moore, Bart.

King Herod was got by Tartar, out of Cypron.

At Newmarket in October, 1763, King Herod beat the Duke of Ancaster's Roman, by Blank, 8st. 7lb. B. C. 500gs. At Newmarket, in April, 1764, he won a sweepstakes of 300gs. each, h. ft. (9 subscribers) 10st. B. C. beating Sir John Moore's (afterwards Mr. Wildman's) Tartar, by Tartar, out of Miss Meredith:—At starting 2 to 1 on King Herod. At Ascot-Heath in June, King Herod 8st. 13lb. beat Lord Rockingham's Tom Tinker, by Sampson, 8st. 7lb. four miles, 1000gs.—4 to 1 on King Herod. At Newmarket in October, King Herod, 8st. 11lb. beat the Duke of Grafton's Antinous, 8st. 8lb. B. C. 500gs.—6 to 4 on Antinous. At Newmarket in May, 1765, King Herod, 9st. beat the Duke of Grafton's Antinous, 8st. 5lb. B. C. 1000gs.—7 to 5 on Antinous. In October, at 9st. he was beat by Sir James Lowther's Ascham, 6 years old, 8st. B. C. 1000gs.—3 to 1 on King Herod. At the decease of his Royal Highness, King Herod was purchased by Sir John Moore; and in April, 1766, at 9st. he was beat by Lord Bolingbroke's Turf, 5 years old, 8st. 8lb. B. C. 1000gs.—At starting, 7 to 4 on King Herod. At York, in August, he started for the subscription-purse against Bay Malton, Jerkin, Royal George, Flylax, and Beaufremont; but a blood-vessel burst in King Herod's head, when running the last mile, which caused him to be taken dangerously

ill, and prevented his coming in a better place than last. At Newmarket, in April, 1767, King Herod was second to Bay Malton, beating Turf and Ascham. And in May, at 5st. 7lb. he beat Mr. Shafto's Ascham, 6st. B. C. 1000gs.—6 to 4 on Ascham. The above were the only times of King Herod's running.

King Herod was a remarkable fine horse, with uncommon power, and allowed to be one of the best bred horses this kingdom ever produced, and as a stallion inferior to none, being sire of a larger number of racers, stallions, and broodmares than any other horse either before or since his time.

**HERON, THE,** is about three feet three inches in length. The bill is six inches long, and is of a dusky colour. The feathers of the head are long, and form an elegant crest. The neck is white; the fore part marked with a double row of black spots. The general colour of the plumage is a blue grey; with the bastard wing, and greater quills, black. The middle of the back is almost bare, and covered by the loose feathers of the scapulars; the feathers of the neck also hang loose over the breast. On each side, under the wing, they are black. The legs are of a dirty green, and the inner edge of the middle claw is serrated.

The female has no crest, and the feathers on the breast are short.

Of all the birds that are known, this is one of the most formidable enemies to the scaly tribe. There is, in fresh waters, scarcely a fish, however large, that the heron will not strike at and wound, though unable to carry it off: but the smaller fry are his chief subsistence; these, pursued by their larger fellows of the deep, are obliged to take refuge in shallow waters, where they find the heron a still more formidable enemy. His method is to wade as far as he can go into the water, and there patiently await the approach of his prey; into which, when it comes within his sight, he darts his bill with inevitable aim. Willoughby says he has seen a heron that had no less than seventeen carp in his belly at once; these he would digest in six or seven hours, and then go to fishing again. "I have seen a carp (he continues) taken out of a heron's belly, nine inches and a half long. Some gentlemen who kept tame herons, to try what quantity one of them would eat in a day, have put several smaller roach and dace in a tub; and they have found him eat fifty in a day, one day with another. In this manner a single heron will destroy seventeen hundred store carp in a single year."

The heron, though he usually takes his prey by wading in the water, frequently also catches it while on the wing: but this is only in shallow waters, where he is able to dart with more certainty than in the deeps; for in this case, though the fish does, at the first sight of its enemy, descend, yet the heron, with his long bill and legs, instantly pins it to the bottom, and thus seizes it securely. In this manner, after having been seen with its long neck for above a minute under the water, he will rise upon the wing with a trout or an eel struggling in his bill. The greedy bird, however, flies to the shore, scarcely gives it time to expire, but swallows it whole, and then returns again to fishing.

*Heron Hawking* was formerly a diversion in this kingdom; and a penalty of twenty shillings was incurred by any person taking the

HERON FAWKING.

eggs of this bird. Its flesh was also in former times much esteemed, being valued at an equal rate with that of the peacock.

In breeding-time, the herons unite together in large societies, and build in the highest trees. Sometimes so many as eighty have been seen in one tree. The nest is made of sticks, and lined with a few rushes and wool, or feathers. The eggs are four or five in number, and of a pale-green colour, marked with black spots.

If taken young, these birds may be tamed; but when the old birds are captured, they soon pine away, refusing every kind of nourishment.

The different parts of the structure of a heron, are admirably adapted to its mode of life. It has long legs for the purpose of wading: a long neck, answerable to these, to reach its prey in the water; and a wide throat to swallow it. Its toes are long, and armed with strong hooked talons; one of which is serrated on the edge, the better to retain the fish. The bill is long and sharp: having serratures towards the point, which stands backwards; these, after the prey is struck, act like the barbs of a fish-hook, in detaining it till the bird has time to seize it with the claws. Its broad, large, concave, and apparently heavy wings for so small a body, are of great use in enabling it to carry its load to the nest, which is sometimes at a great distance. Dr. Derham tells us, that he has seen lying scattered under the trees of a large heronry, fishes several inches in length, which must have been conveyed by the birds from the distance of several miles: and D'Acre Barret, Esq. the owner of this heronry, saw a large eel that had been conveyed thither by one of them, notwithstanding the inconvenience that it must have experienced from the fish writhing and twisting about.

The body of the heron is very small, and always lean; and the skin is said to be scarcely thicker than what is called goldbeater's skin. It is very probable that this bird is capable of long abstinence; as its usual food cannot be had at all times.

**HIDE-BOUND.** A horse is said to be hide-bound when his skin sticks so close to his ribs that it seems immovable; but this is not to be accounted an original disease, but only a symptom, which may either be caused by want of sufficient food, or from harassing horses beyond their strength, without allowing them sufficient time for rest and necessary refreshment. Sometimes horses grow hide-bound very suddenly, from fevers and convulsive disorders; and, if that symptom is not suddenly removed, the disorders that occasion it generally prove mortal; but nothing is more common than to see surfeited horses also hide-bound; and therefore, in the cure of all hide-bound horses, regard must be had to the original cause from whence it proceeds.

The diet of hide-bound horses should be cool and opening, as scalded bran or

barley; an ounce of fenugreek seeds should be given in his feeds for a month, or longer. As this often proceeds from worms, it may be necessary to give the medicines common in those cases.

**HIGHFLYER.** A bay horse, foaled in 1774, bred by Sir Thomas Charles Bunbury, Bart. sold to Lord Viscount Bolingbroke, and afterwards to Mr. Richard Tattersall.

Highflyer was got by King Herod, out of Rachel, the dam of Marc Antony, &c.

At Newmarket second October meeting, 1777, Highflyer won a sweepstakes of 100gs. each, p. p. (9 subscribers) colts, 8st. fillies, 7st. 11lb. Ditch-in, beating Lord Grosvenor's Justice, Mr. Douglas's Bourdeaux, Sir C. Bunbury's Sweetmarjoram, and Gen. Parker's Lyra:—6 to 4 against Bordeaux, 2 to 1 against Justice, and 4 to 1 against Highflyer, who was

much out of condition. This was his first engagement.

At Newmarket second spring meeting, 1778, Highflyer won a sweepstakes of 100gs. each, p. p. (26 subscribers) colts, 8st. fillies 7st. 11lb. B. C. beating Lord Clermont's Il'mio, Mr. O'Kelly's Thunderbolt, Mr. O'Kelly's Jupiter, Mr. Sparhawk's Chesfield, Lord March's Fulminé; Lord Grosvenor's ches. colt, by Chymist, out of Barbary's dam; Duke of Bolton's Hanghim, Mr. Hervey's Receiver, and Lord Grosvenor's Justice who broke down:—6 to 4 on Highflyer. In the July meeting, he won the Grosvenor stakes of 25gs. each, (24 subscribers) colts, 8st. 7lb. fillies, 8st. 4lb. B. C. beating the Duke of Grafton's Stormer, Mr. Pigot's Satellite, and Lord Claremont's Dragon:—4 to 1 on Highflyer. On Monday, in the first October meeting, he won the renewed 1400gs. a subscription of 200gs. each, h. ft. (10 subscribers;) colts, 8st. 10lb. fillies, 8st. 7lb. B. C. beating Lord Clermont's Il'mio, Mr. Vernon's Firm, and Mr. O'Kelly's Jupiter:—9 to 1 on Highflyer. On Thursday, at 7st. 4lb. he won the weights and scales purse of 100gs. free for any horse, &c. B. C. beating Mr. Harvey's Pearl, 5 years old, 8st. 5lb.; Sir J. Moore's Vestal, 4 years old, 7st. 4lb.; and Sir C. Davers's Tremamondo, 5 years old, 8st. 5lb.:—very high odds on Highflyer. In the second October meeting, he received forfeit in a post stakes of 200gs. each, h. ft. (5 subscribers) colts, 8st. 7lb. fillies, 8st. 4lb. B. C. amongst those named, were Jupiter, Thunderbolt, Flash, Dragon, Cupid, and Marphisa. In the Houghton meeting, at 8st. he beat Lord Clermont's Dictator, 5 years old, 8st. 7lb. B. C. 500gs.:—2 to 1 on Highflyer.

At Newmarket first spring meeting, 1779, Highflyer, 8st. 3lb. won a sweepstakes of 300gs. each, h. ft. B. C. beating Mr. Stapleton's Magog, 8st. 7lb.—Lord Clermont's Dictator, 8st. 8lb. paid:—4 to 1 on Highflyer. In the second spring meeting, he won a sweepstakes of 200gs. each, h. ft. 8st 7lb. each, B. C. beating Lord Ossory's Dorimant, aged; and Lord Clermont's Dictator, 6 years old:—Shark, aged, paid:—4 to 1 on Highflyer. He was sold to Mr. Tattersall; and at Nottingham, August 4, he walked over for a subscription of 10gs. each, (21 subscribers) with 70gs. added by the Grand Stand, for all ages, twice round the course. On Wednesday, in the York August meeting, he walked over for the subscription purse of 295l. for five-year olds, 9st. four miles.

And the next day he won the subscription purse of 295l. for six-year olds, 8st. 7lb. and aged, 9st. four miles, beating Sir J. Pennyman's Venetian, aged:—20 to 1 on Highflyer. And at Lichfield, September 14, he won the King's purse of 100gs. for five-year olds, 8st. 7lb. three-mile heats, beating Lord Grosvenor's Crosspatch, and Mr. Smallman's Chesfield, who was third and drawn:—10 to 1 on Highflyer, who was lame, and out of condition, notwithstanding he won easy. This was the last time of his running, and the above were his only engagements: therefore, he was never beat, nor ever paid a forfeit, though it has been asserted, to the contrary: he was undoubtedly the best horse of his time in England. The sums he won and received amount to 9336 pounds, 10 shillings, although he never started after five years old.

Highflyer then became a stallion at Ely, (afterwards called Highflyer Hall) Cambridgeshire, where he covered mares in 1780, 1781, 1782, 1783, 1784, 1785, 1786, and 1787, at 15gs. and 10s 6d.; in 1788, at 15gs. and one guinea; in 1789, at 25gs. and one guinea; in 1790 and 1791, at 30gs. and one guinea; in 1792, at 50gs. and one guinea; and 1793, at 30gs. and one guinea. He was a very valuable stallion, and sire of an uncommon number of capital racers, stallions, and brood-mares, several of whose pedigrees, performances, and produce will be given in the course of this volume. He was also a most sure foal-getter, and got considerably more colts than fillies. He got only one or two 'chestnuts, one of which was Mr. Montolieu's Little Luna.

HIND. The stag's female.

HIP-SHOT. The defect so termed is an injury frequently sustained in the hip joint, but not always with the same degree of severity. It is a ligamentary twist, by which the junction of the bones is materially affected, but not amounting to absolute dislocation; although it may proceed from a variety of causes, in sudden shocks from the different prominences of, or cavities in, an uneven and irregular pavement; blows, strains, or wrenches, as well as by sliding, or falling; yet there is little doubt but it occurs much oftener from carelessness, inattention, and brutality, either by a violent blow from the post of the stable door, in being hastily led in or out, than by any other means whatever. A cure is seldom effected; for as the injury is not only deeply, but critically, seated, so if the horse, after any

medical means have been used, is turned out to obtain strength, a repetition of work generally produces a relapse of the injury.

**HOCK OR HOUGH.** See **HAM**.

**HOG-STEER.** A wild boar three years old.

**HOLD HARD!** A well known term used in the chase; and applied to those who ride too forward, or press on too much.—It may perhaps be regarded as the opposite of *Hark forward!*

**HOOF.** The hoof of a horse is that hard and horny substance at the lower extremity of the legs, coming into contact with the ground, and upon which are placed shoes, made of iron, for the preservation of the feet.

**HOOF-BOUND.** We say a horse is hoof-bound when the hoof is so tight round the instep that it turns the foot somewhat into the shape of a bell. This may be occasioned by an excessive hardness and thickness of the crust; but it is more frequently caused by bad shoeing, especially in the attempts of farriers to widen the heel. Sometimes cutting the toes down too much will give that shape to the foot, and cause a horse to go lame; but this is easily discovered both by the eye and by a horse setting his foot down tenderly. Gibson says, he has known horses that have had so much of the toes cut down, that they could not go till all the nails were pulled out before. According to that writer, the only way to relieve the binding of the hoof is “to draw the foot down from the coronet almost to the toe with a drawing-knife, making seven or eight lines or razes through the hoof, almost to the quick; afterwards keep it charged with pitch or rosin, till the lines are worn out in shoeing, which will require several months.” Most people, for this reason, turn such horses to grass till the feet grow down.

**HOOF-CASTING.** A complete separation of the horse's hoof. This may be occasioned by whatever accident may bring an imposthumation in the foot, by which the whole hoof becomes loosened, and falls off from the bone. If the coffin-bone remains uninjured, a new hoof may be procured by the following method: apply to the part any mild ointment or dressing spread upon tow; then make a boot of leather, with a strong sole, to be laced fast about the pastern, bolstering and stopping the foot with soft flax, that the tread may be easy; renewing the dressing every day until the new hoof grow. Some dress the sore with the fine

powder of myrrh, in order to prevent a fungus; sometimes burnt alum or precipitate is added to it, and the luxuriant flesh daily washed with lime-water. The old hoof should by no means be pulled off, unless circumstances happen that require its removal; for it serves as a defence to the new one, and makes it grow more smooth and even; and, indeed, nature will effect this at her own proper time.

**HORSE.** It is not easy to say from what country the horse came originally. It should seem that the colder climates do not agree with his constitution; for although he is found almost in them all, yet his form is altered there, and he is found at once diminutive and ill-shaped. We have the testimony of the ancients, that there were wild horses once in Europe: at present, however, they are totally brought under subjection; and even those which are found in America are of a Spanish breed, which, being sent thither on its first discovery, have since become wild, and have spread all over the south of that vast continent, almost to the Straits of Magellan. These, in general, are a small breed, of about fourteen hands high. They have thick jaws and clumsy joints; their ears and neck, also, are long; they are easily tamed; for the horse by nature is a gentle complying creature, and resists rather from fear than obstinacy.

These American horses, however, cannot properly be ranked among the wild races, since they were originally bred from such as were tame. It is not in the new, but the old world that we are to look for this animal, in a true state of nature: in the extensive deserts of Africa, in Arabia, and those wide spread countries that separate Tartary from the more southern nations. Vast droves of these animals are seen wild among the Tartars; they are of small breed, extremely swift, and very readily evade their pursuers. As they go together, they will not admit any strange animals among them, though even of their own kind. Whenever they find a tame horse attempting to associate with them, they instantly gather round him, and soon oblige him to seek safety by flight. There are vast numbers also of wild horses to the north of China, but they are of a weak, timid breed; small of stature, and useless in war.

But of all countries in the world, Arabia produces the most beautiful breed, the most generous, swift, and persevering.

They are found, though not in great

numbers, in the deserts of that country; and the natives use every stratagem to take them. Although they are active and beautiful, yet they are not so large as those that are bred up tame; they are of a brown colour, their mane and tail very short, and the hair black and tufted.

The value of Arabian horses, over all the world, has, in a great measure, thinned the deserts of the wild breed; and there are few, if any, to be found in those countries except such as are tame. The Arabians, as we are told by historians, first began the management of horses in the time of Sheque Ismael. Before that, they wandered wild along the face of the country, neglected and useless; but the natives then first began to tame their fierceness, and to improve their beauty; so that at present they possess a race of the most beautiful horses in the world, with which they drive a trade, and furnish the stables of princes at immense prices.

There is scarce an Arabian, how poor soever, but is provided with his horse. They, in general, make use of mares in their ordinary excursions; they are less vicious, of a gentle nature, and are not so apt to neigh. They are more harmless also among themselves, not so apt to kick or hurt each other, but remain whole days together without the least mischief. The Turks, on the contrary, are not fond of mares; and the Arabians sell them such horses as they do not choose to keep for stallions at home. They preserve the pedigree of their horses with great care, and for several ages back. They know their alliances and all their genealogy; they distinguish the races by different names, and divide them into three classes. The first is that of the nobles, the ancient breed, and unadulterated on either side; the second is that of the horses of the ancient race, but adulterated; and the third is that of the common and inferior kind: the last they sell at a low price; but those of the first class, and even of the second, amongst which are found horses of equal value to the former, are sold extremely dear. They know, by long experience, the race of a horse by his appearance; they can tell the name, the surname, the colour, and the marks properly belonging to each. When they are not possessed of stallions of the noble race themselves, for their mares, they borrow from their neighbours, paying a proper price, as with us, and receive a written attestation of the whole. In this attestation is con-

tained the name of the horse and the mare, and their respective genealogies. When the mare has produced her foal, new witnesses are called, and a new attestation signed, in which are described the marks of the foal, and the day noted when it was brought forth. These attestations increase the value of the horse; and they are given to the person who buys him. The most ordinary mare of this race sells for five hundred crowns; there are many that sell for a thousand; and some of the very finest kinds for fourteen or fifteen hundred pounds. As the Arabians have no other house but a tent to live in, this also serves them for a stable, so that the mare, the foal, the husband, the wife, and the children, lie altogether indiscriminately; the little children are often seen upon the body, or the neck, of the mare, while these continue inoffensive and harmless, permitting them thus to play with and caress them without any injury. The Arabians never beat their horses: they treat them gently; they speak to them and seem to hold a discourse; they use them as friends; they never attempt to increase their speed by the whip, nor spur them but in cases of necessity. The Arabian horses are small, easy in their motions, and rather inclined to leanness than fat. They are regularly dressed every morning and evening, and with such care that the smallest roughness is not left upon their skins. They wash the legs, the mane, and the tail, which they never cut; and which they seldom comb, lest they should thin the hair. They give them nothing to eat during the day; they only give them to drink once or twice; and at sun-set they hang a bag to their heads, in which there is about half a bushel of clean barley. They continue eating the whole night, and the bag is again taken away the next morning. They are turned out to pasture in the beginning of March, when the grass is pretty high, and at which time the mares are given to the stallion. When the spring is past, they take them again from the pasture, and they get neither grass nor hay during the rest of the year; barley is their only food, except now and then a little straw. The mane of the foal is always clipped when about a year or eighteen months old, in order to make it stronger and thicker. They begin to break them at two years old, or two years and a half at farthest; they never saddle or bridle them till that age; and then they are always kept ready saddled at the door of the tent

from morning till sun-set, in order to be prepared against any surprise.
